 Burning clay for manure 218—burning sod 316.
 Burrall Thomas D. Esq. his address to the Ontario Agricultural Society 194.
 Burying ground, national, remarks on 206.
 Burying dead in populous cities condemned 323, 394.
 Bushes, on the best mode of killing 306.
 Butter, how made 12—to take a rancid taste from 12—to make from scalded cream 12, 159—receipt for curing 12—salt, how made fresh 66—how best made in cold weather 108—method of making good from cows fed on turnips 123—great quantities of made by John M. Graham 119—Mr. Pickering's remarks on 220—general directions for making 324, 364, 391.

C.

C. his communication on the properties of an unit 158.
 Cabbages, on the cultivation of 293, 349—great crops of 363.
 Calendar, farmers', indicated by the budding of trees. &c. 21, 22.
 Calves, best mode of feeding and raising 122, 324.
 Canada thistles, how destroyed 30, 280, 398.
 Canal from Worcester to Providence 186.
 Candles with wooden wicks, notice of 39.
 Capital, necessary for a farmer 29.
 Carrot, on the cultivation of 265, 293.
 Cashmere Goat, and its importation into France, remarks on 188.
 Catarrh in cattle, remedy for 177.
 Caterpillars that destroy grass, Dr. Harris's description of, and remedy against 238, 365—description of Col. Pickering's brush for destroying 308—other modes of destroying 362, 371, 379.
 Cattle, breeds of much improved since 1700, 1—mode of fattening 12, 133—improvement of 134, 156—how to distinguish those which are inclined to fatten 162—diseases of 169, 177, 185, 193, 201, 209, 225, 232, 249, 257—large ones in Germany 19—swollen or hoven, remedy for 46—weight of, how ascertained by measurement 63—breeding of 67—best shape for 109—different kinds 204—remarks on 213, 228—large, owned by Mr. Rice 251—Mr. Wilkinson's remarks on 252, 260, 268—breeding in and in to too great an extent not advisable 270—fine, belonging to Mr. Monmouth Purdy 271—North Devon, their prices in England 299—to remove vermin from 307—on making very fat 313—proper age for fattening ib.—best food for fattening ib.—Col. Jaques' breed, notice of 350—breeds of remarked on by Curwen 362.
 Cattle Sheds, query concerning 347.
 Cattle Shows—at Worcester 43, 71, 74; at Brighton 66, 86, 97; at Amherst, N. H. 79; at Concord 81; at Windsor, Vt. 83; at Burlington, Vt. 83; at Pawtuxet, R. I. 101; at Exeter, N. H. 101; at Middlebury, Vt. 101; at Acworth, N. H. 92; at Pittsfield 93; at Plymouth 94; at Hartford, Ct. 94; at Windham, Ct. 109; at Northampton 114; at Granby, Ct. 115; at New York 130; at Virginia 154.
 Cattle stalls, Col. Pickering's remarks on their inconveniences 108.
 Cement for water cisterns 204.
 Charcoal, pulverized, a cure for dysentery 37—polishing powder from 356.
 Chemistry of use in farming 149.
 Cholera Morbus, cure for 29.
 Church Dr. his Printing Press, notice of 355.
 Churches, how secured from fire 179.
 Churn-dasher, improvement in 12.
 Cider, bottled, how kept from bursting 37—an essay on 76—fixed air should be retained in 149—vessels for the best are hog-heads made of oak and iron bound 155—Col. Pickering's remarks on 220—mode of making adopted by the religious society called Shakers 277.

Cider-brandy, how mixed with cider, to make cider wine 37.
 Cider-oil, or more properly, cider royal, how made 227.
 Cisterns, on the construction of 204. [254.]
 Clearing of land, best modes of 129, 172.
 Clothes of females, when they have taken fire, how extinguished 142, 232.
 Clover hay should be salted at the rate of one peck for a ton 12.
 Clover seed, on gathering and cleaning 202.
 Clover, white, on saving the seed of 395.
 Coal discovered near Detroit 360.
 Cobs of Indian corn, said to be valuable as food for cattle 223.
 Cock-chaffer, a destructive insect, notices of 102, 112, 118, 128.
 Colic in cattle 201.
 Columella, his remarks on educating plough boys 170.
 Combustion, spontaneous, instances of 53, 143, 168.
 Composts, directions for making 321.
 Consumption, caused by carelessness in clothing 293.
 Cookery, country, general cautions respecting 369.
 Cooking food for cattle 22, 30, 33.
 Cooper Thomas, M. D. his axioms in husbandry 66.
 Copperas, Vermont, Dr. Locke's description of 326.
 Corn, sweet, notices of 3, 43. *See Indian Corn.*
 Cosmetic, superior, for ladies 3.
 Cotton, cultivation of in New York and New Jersey 62—on Long Island 216.
 Cow, marks of a good one 21—in her prime at five years old 21.
 Cows, warm water for in winter recommended 108—when fed with cabbages the decayed leaves should be taken off 148—should not be exhausted by too much milking 157—those which give the greatest quantity of thin milk most proper for suckling calves 157—difference of milk in ib.—on the management of when near calving 233.
 Coxe, Wm. his mode of managing a millet crop 299.
 Cream, method of preserving 37.
 Crickets, how destroyed 28.
 Crops, of potatoes, mangel wurtzel, &c. much greater now than thirty years ago 1—fallow, Mr. Pickering's remarks on 36.
 Croup, a remedy for 72.
 Crowninshield Richard, Esq. his remarks on cultivating Wood 387.
 Cucumber, on cultivating 392, 363.
 Currants, how propagated 310.
 Curwen, his remarks on breeds of cattle 362.
 Cutlery, American, in Pittsburgh, notice of 163.

D.

Dairy, a remarkable one, near Baltimore 251.
 Dana, Professor J. F. his remarks on bleaching flax 62—his account of a disease in neat cattle in Burton, N. H. 103—notice of his lectures 254.
 Dana Samuel, Esq. his communication respecting straw for Leghorn hats 212.
 Dandelions, medical uses of 331.
 Davis Gideon, notice of his substratum plough 366.
 Davis Lemuel, his statement relative to raising Indian corn 8, 342.
 Deane's edition of New England Farmer, notice of 3.
 Dentifrice of alum and sage, from Markham's English Housewife 143.
 Diamonds obtained from charcoal 371.
 Diarrhoea in cattle 209.
 Ditching, may be begun in winter 171.
 Divining rods, remarks on 67.
 Dogs, distemper in, cure for 73—the labor they perform in Holland 320.
 Dog-star and dog-days, origin of those terms 24.
 Draining lands, Mr. Elkington's mode of 409.
 Dress, or clothing, useful remarks on 250—females' on fire, how managed 142, 232.
 Drilling Match in Nova Scotia, account of 412.
 Drought in the southern states, notice of 40.
 Drowned persons, directions for recovering 163.
 Dry rot in timber, cause of, and how prevented 340.
 Dung too much rotted of no value 393. *See Manure.*

E.

Eaton Peter, D. D. his address to the Essex Agricultural Society 244.
 Elder, virtues and uses of 3, 113.
 —juice, kills skippers in bacca, &c. 3, 46.

Embankments, dikes, &c. how constructed for reclaiming land from the sea 241.
 Experimental farms, utility of 154.

F.

F. his remarks on preparing wool for market 368.
 Fall fevers, garlic said to preserve against 335.
 Farmer, on the capital necessary for 13—signs of a good one 133.
 Farmer A. his communication recommending the New England Farmer 47—on a worm that destroys grass 47, 77—on the best mode of constructing gates 129—on destroying thistles 230—on securing potatoes in autumn 354—on feeding swine with brakes 378.
 —a Pennsylvania, on farmers who do not work it right 117.
 —a Roxbury, his notice of the products of the season 2, 90, 343.
 —a young, &c. on early cutting grain, plaster of Paris, &c. 94.
 Farming societies recommended 219.
 Farwell, Mr. A. his remarks on making manure from swine 232.
 Fastening for doors and window shutters 359.
 Fences should be attended too early in the spring 286.
 Fessenden Thomas G. his address to the Middlesex Society of Husbandmen and Manufacturers 39.
 Fever, inflammatory, in cattle 169.
 Fish, directions for curing 184.
 Fish oil, or vegetable oil, purified by tan 142.
 Fiske, Dr. his notice of an excellent breed of swine 107, on attention to the selection of seed 222.
 Flax, remarks on the preparation of, in a letter from S. W. Pomeroy, Esq. to Gov. Wolcott 50—Professor Dana's remarks on bleaching of 62—machine for dressing 54, 322—dressed so as to resemble silk 330.
 Food, plain & good, with little meat, how made 20, 21.
 Forest trees, observations on 305, 329.
 Founder in horses, cure for 19.
 Fruit, matured by painting walls black 103.
 —trees, a Norfolk Gardener's remarks on 34—mode of engrafting 121—observations on, by Rev. Abiel Abbot 141—by Mr. Abner Landrum 145—on promoting the growth of 170—to prevent the premature decay of 187—on pruning 278, 309—best time and manner of planting 301—should be pruned in the spring when the buds begin to swell 309—should be secured against cattle 317—quere relative to cutting off the fibres in planting 318—Marshall's directions concerning planting 318—how protected from frost 322—how produced by planting cions 331.
 Fuller's earth, discovered on North River 166—description and uses of 166.

G.

Gardiner Lyceum, a seminary for the education of mechanics, notice of 124.
 Garlic, said to be an antidote to fall fevers 335.
 Garnet, Mr. his address to the Fredericksburgh Agricultural Society 164.
 Gas, how obtained from oil 113.
 Gate, on the best mode of constructing 129.
 German, a, his remarks on taking honey from bees in Germany 322.
 Gestation, period of in different animals 138.
 Glass, easy mode of breaking in any direction 131.
 Gold, on the great ductility of 234—mine discovered in North Carolina 363.
 Goodsell's flax machine, recommendations of 339.
 Gorham, Dr. his analysis of Indian corn 356.
 Grain, should be cut early 94—on preserving and improving the quality of 297.
 Grain-sick, a disease in cattle 249.
 Grapes, mode of propagating 294.
 Grass, on laying down land to 153.
 —land, on sowing 278.
 Grasses, experiments on the evaporation of 235.
 Gravel, said to be cured by the wild carrot 268.
 Green crops, on turning in, Mr. Pomeroy's remarks on 9—Mr. Pickering's do. 221.
 Green-gage, a plum, notice of 19.

H.

Hale, Hon. S. his address delivered before the Cheshire Agricultural Society 234.
 Harris, Dr. T. W. his description of and remedy against the caterpillar which destroys grass in salt meadows 238, 385.

Harris, Rev. T. M. his remarks on destroying insects by lights burning 379.
 Haslam John, veterinary surgeon, his remarks respecting bots in horses 339.
 Hats, premium, notice of 103—made of spear grass 150.
 Hay, should be cut or chafed for feeding cattle 12—should be salted 12, 399—taken off a cart or waggon by hooks 378.
 Hay-making, observations on 373.
 Head aches and apoplexy attributed to wearing too tight cravats 366.
 Hemp, quantity of necessary to fit out a man of war 24.
 Herdsman, his plan for a cow-house 379.
 Hessian Fly, Professor Green's remarks on 113—feeding wheat with sheep supposed to be remedy against 347, 351—remarks on 351, 355, 410.
 H. H. D. a writer with that signature 125.
 Hoeing corn and garden vegetables, remarks on 389.
 Honey, description of a mode of taking 347.
 Honor, modern, ridiculed 147.
 Hoof-ail in cattle, remarks on and remedies for 223.
 Hops, on the cultivation of 73, 395.
 Horn distemper, in cattle, its symptoms & remedy 257.
 Horse, on the points of 33—hoofs of described 33—cure of a broken winded 35—diseases of 45—power of 148.
 Horse-rake, description of 389, 398.
 Horses, how saved from barns on fire 123—English turf, not a useful breed in the United States 267.
 Horse shoes, patent, made in two pieces 149.
 Horse shoeing, new system of 199.
 Hoven or blown, a disease in cattle, symptoms and remedy 193.
 Howe Timothy, notice of his threshing machine 363.
 Hull, Gen. his mode of cultivating carrots and ruta baga 265.
 Husbandry, axioms in 66, 113.
 Hydraulics, description of tools used in boring for water 360.
 Hydrophobia, fatal instances of 19, 151.

I.

Ice, how it may be kept in a common cellar 114.
 Implements in agriculture, new and improved, remarks on 198, 205.
 Indian corn, Mr. Davis' mode of planting 3—Col. Pickering's remarks on 36—a second crop of 88—boiling it for hogs recommended 108—how raised by Thomas Shepherd, Esq. 116—great crops of raised by J. & M. Pratt 117—Col. Valentine's cultivation of 178—too costly food for fattening cattle on 234—new kind of 265—Gen. Hull's mode of cultivating 265—successful culture of by John Lees 332—by Henry Little 332—how planted, &c. 341—remarks on its cultivation 341, 342, 365—on the various modes of preparing and using it 348—how raised for fodder 366—quere whether best to take off the suckers 8, 390—hilling of should not be delayed till haying 397.
 Indicator, his observations relative to the time of putting seeds into the ground, to be learned by the growth of asparagus, &c. 21.
 Indigo plant, wild, notice of 32.
 Inflammation in the stomach of cattle 125—of the liver of do. ib.—of the kidneys of do. ib.
 Insects, remedies against 46, 293, 294—those which destroy fruit trees, remarks on 317—destroyed by soap suds 333—cabbage plants should be guarded against, and how 350—vines, &c. guarded against by boxes, &c. 377—those which destroy Indian corn in the field, antidotes against 371, 377, 378—destroyed by flying at a light 376.
 Instinct, animals, remarkable instance of 376.
 Irrigating lands, remarks on 113, 317.

J.

Janes, Mr. his speech in New York legislature on the bill for repealing the law for the improvement of agriculture 298.
 Jacques, Col. notice of his breed of cattle 302, 350.
 Jaundice in cattle, symptoms and remedy 201.
 Joint oil, loss of in cattle 257.

K.

Kenrick John Esq. his remarks on the best time for felling timber 223, 229, 234.
 Knight, Mr. A. Adams, report on his crop of onions 178.
 Knight, Thomas Andrew, on mildew 414.

L.

loom, notice of 203.
 add William Esq. his address before the Agricultural Society of Maine 236.
 and, worn out, how renovated by sowing with clover, and ploughing in the crop 364, 366.
 andrum, Mr. Abner, his observations on fruit trees 145.
 arch tree, notices of 59.
 aw, Mr. Thomas, his remarks on burning soil 316.
 ead colic, account of 270.
 eaden pipes, water which has stood in over night should be emptied 40.
 ees, Mr. John, his communication respecting the culture of Indian corn 332.
 eghorn hats, on the manufacture of in Italy 192.
 straw, communication respecting, from the Hon. Samuel Dana 212.
 ice on apple trees, description of, how destroyed 333.
 ife-preserver, a dress for swimming so called, notice of 40.
 ighting, wet clothes conductors of 3.
 ime, should not be mixed with fresh dung while hot, or in its caustic state 12—how applied to soils, &c. 92, 218—increases the productions of the earth 139—how to preserve horses feet from its effects 141—method of ascertaining its qualities 277—on using it with manure 306, 334.
 ime-stone, magnesian, remarks on 143.
 incolin, Hon. Levi, extracts from his address to the Worcester Agricultural Society 180—his remarks on ruta бага 315.
 liquid manure, Mr. Young's and Col. Pickering's remarks on 219. *See further Manure.*

 ittle Wallis, on curing bacon 251—on raising English turnips 258—on relieving cattle, when choked with apples, roots, &c. 258, 259.
 ittle Henry, his statement relative to the culture of Indian corn, &c. 332.
 ittle Silas and Joseph, their statement relative to the cultivation of turnips 332.
 ive stock, Col. Pickering's remarks on 220.
 ong life, rules for attaining 312—instances of 376.
 owell John, Esq. his remarks on the manner of conducting the Massachusetts Agricultural Journal 1—on soiling 10—on horticulture, &c. 11—his directions for cultivating and preserving the sweet potatoe 210, 370.

M.

achine, for cutting furs from skios 144.
 agnet, chemical agency of 171.
 angel Wurtzel, autumn ploughing and broad cast manuring recommended for 28—David Little's cultivation of 178—Col. Powell's remarks on 276—Judge Prescott's statement relating to its cultivation 338—D. Little's crop of 340—on feeding sheep with 348.
 lange in cattle 163, 257.
 lanure, does not sink in the soil 36—liquid, Mr. R. Smith's observations on 44, [see also liquid manure] on saving and making the most of 54, 62, 36, 110, 134, 150, 174, 190, 214, 221, 321—how best made from swine 232.
 laple sugar, cultivation of recommended 305.
 married persons, address to from the clergyman at the altar 334.
 Massachusetts Agr. Repository, notices of 1, 390.
 fats, new method of weaving 115.
 leadow land, wet how reclaimed 246.
 leat, tainted, how cured 66—how preserved by charcoal ib. *See further receipts.*
 lidew not remedied by salt 148—how prevented in late sown peas 414.
 liddlesex husbandman, his remarks on the causes and treatment of pauperism 157.
 ilk, remarks on 324.
 illet, the cultivation of recommended 59—crop of raised in Wilmington 83—Col. Powell's statement concerning 277—Mr. Coxe's mode of gathering a crop of 299.
 lineralogical, a series of essays, so entitled 124, 133, 140, 153, 161.
 lineral spring, in Bradford, E. Parish, notice of 351.
 litchell, Dr. his address to the New York Agricultural Society 137.

Mortar, theory of the formation of 44.
 Mortification, balsam of Peru, a remedy for 342.
 Moths, sweet flag a remedy against 227.
 Mowing ground should be harrowed, rolled, and top dressed after haying 413.
 Mowing machine, notice of 398.
 Mowing match, notice of 55.

N.

New England and Virginia, comparison between, as respects expenses of house keeping, &c. 400.
 Nichols Andrew, Esq. extracts from his address to the Essex Agricultural Society 113, 114.
 Nut-galls, native, notice of 38.

O.

Oak, how cultivated 305, 404.
 Oats, eighty-five bushels raised on an acre 55—Mr. H. Stevens' observations on the culture and uses of 253.
 Oil essential, how obtained from flowers 299—of Gilead how obtained 299.
 Old Colony Farmer, his remarks on imported cattle, and the answer 266.
 Onions, Mr. Adam Knight's premium crop of 178—how to cultivate 302.
 Opium, best administered with lemon or lime juice 141.
 Orchardis, American, notice of 230.
 Orchards, remarks on by John Welles, Esq. 372.
 Ovens, how constructed to save fuel 374.
 Ox, weighing 2420 pounds 294.
 Oxen, working, how to manage them when they will not work well together 20—potatoes proper food for in the spring 278.

P.

Paint, fresh, the cause of sudden death 94.
 Painting houses should be done in autumn or winter 314.
 Panda, a delicate diet for a weak stomach, how made 227.
 Paring and burning, new method of 20.
 Parsnips, how cultivated 294, 326—raised to advantage with peas 351.
 Parsons Gorham, Esq. his note to the editor respecting the breed of horses 267.
 Pastures, observations on those which are permanent, not to be ploughed up unless they can be enriched 297—cattle should not be turned into too early in the spring 317.
 Patented machines said to be charged too high 29.
 Patent office, remarks on 208.
 Peaches, mode of drying 227.
 Peach trees, insects injurious to, destroyed by walnut shells 107—Mr. Coulter's method of cultivating 186—remedy for grubs in 317—how they may be forced to bear 326.
 Pear, weighing 34 ounces, notice of 103.
 Peas, on the cultivation of 11, 279—late, saved from mildew by frequent watering 414.
 Perfumes prevent mouldiness 315.
 Perkins' steam engine, notice of 392.
 Peters Lovett, his receipt for diarrhoea in calves 234.
 Peters, Hon. Richard, his account of Tunisian sheep 34, 202.
 Petrification, notice of a dead body petrified 24.
 Petrified animals, curious discoveries of 208.
 Pickering, Hon. Timothy, his remarks on raising peas free from bugs 11—on the folly of regarding the moon in agriculture 11—on the best time for felling trees for timber 17, 250—his observations respecting manure's not being liable to sink in what is called riddle land 36—on live stock, thinks premiums should be given for the most valuable breeds of cattle instead of those which are biggest and fattest 36, 220—on Indian corn sowed for fodder 36—on fallow crops ib.—on deep ploughing 60—on cattle stalls 108—his address to the Massachusetts Agricultural Society 217—on the food of plants ib.—on lime, and the earths which constitute a fruitful soil ib.—on burning clay for manure 218—on the slow progress of knowledge in husbandry 218, 219—on materials for manure 219—on liquid manure 219, 220—on cider 220—on turning in green crops 221, 269—on trench ploughing 221—on premiums for new objects of agricultural improvement, and on new principles 221, 289, 290, 291—on dairy soiling 289—his description of a brush for destroying caterpillars 308—notice of

the part taken by him in the celebration of the 4th of July, at Salem 391.
 Pies, more advantageous for food than roasting or boiling 20.
 Plaster of Paris, new application of to clover, previous to ploughing it down for a wheat crop 44—operated beneficially three years after it was applied 94.
 Pleurisy in cattle, description of and remedy 177.
 Pliny's natural history, extract from 71.
 Plough, Davis' substratum, notice of 366.
 Plough-cleaner, description of 107.
 Ploughing, deep, remarks on by several authors 60—should generally be performed in the fall 278—different modes of on different soils 393.
 Ploughing, horizontally, description of a machine for, and remarks on 14.
 Plumbago, or black lead, discovered in Bristol, New Hampshire 127.
 Plymotheus, his remarks on a worm that destroys corn and grass 61.
 Poetry—Agriculture 16—the milk maid and the banker ib.—the lawyer and the chimney sweep ib.—fly not yet 24—the evils of a mischievous tongue 32—the rich man and poor boy 40—the scholar who lost his key-hole ib.—home 48—the milk maid and her lover 56—a man to my mind 61—a man not to my mind ib.—the fox and the ant 72—on the necessity for laborious work 80—rural life 88—husbandman's holiday 96—love relishes the coarsest fare 112—antidotes to ambition 120—rural felicity 123—scolding wife 136—self puffing ib.—on a purse proud block-head ib.—on the miseries endured by a post horse 144—rural scenery 152—on health 160—the fleece 168—on a man's enjoying the good of his labor 176—on governing the passions 181—the pig and the connoisseurs 192—song, on a farmer's life 200—to a New England poet 208—ceremony, or more compliments than courtesy 216—the wearisomeness of what is called a life of pleasure 224—the sleep of the slug-gard 232—a merry heart doeth good like a medicine 240—farmer's lot 248—a moral lesson 256—on the laughter of fools 261—rural peace and independence 272—the farmer 280—on the vowels ib.—contented farmer 288—an acre of corn 296—on the sensibility of the brute creation to changes in the weather 304—address to the hon. speaker B....w, on peaches presented by him 320—invocation to spring 328—on the art of pruning wall trees 336—American sketches 344—ode to innocence 352—pot luck 360—odes for the celebration of the centennial anniversary in New Hampshire 363—rural scenes 376—the French peasant 384—splendor of the setting sun 392—ode for the 4th July 400—the happy man 408—sonnet 416.
 Pomeroy, S. W. Esq. his essay on the advantages of manuring with green crops 9—his letter on bleaching 71—his letter to Gov. Wolcott on the preparation of flax 50.
 Pomona, an essay on cider, written by 76.
 Ponds, for watering cattle, how made 236.
 Population of the United States, remarks on 184.
 Porcelain clay, American, discovered 247.
 Potatoes, greater crops of raised now than thirty years since 1—best economy to plant large, or at least middle sized 1, 2, 286—may be spoiled by bad management in harvest 5—should be boiled, steamed or baked for feeding stock ib.—not proper for milch cows ib.—raw, good for working oxen in the spring ib.—tops of may make a good fodder 20—pudding made of ib.—bread made of ib.—how preserved by peeling, rasping and pressing ib.—experiments by J. W. on the best mode of planting 53—mode of preserving in fine sand 108—when spoiled, how to be managed ib.—when given raw inferior to boiled or steamed 45 per cent 117—503 bushels of to an acre, raised by Joseph Watson Jr. 259—on the cultivation of 286, 325—best planted whole 286, 330—a farmer's remarks on securing them in autumn 354.
 Potatoes, sweet, best mode of cultivating 210, 307, 370.
 Poultry, how kept by Mr. Wakefield 5—molasses mixed with their food profitable ib.—corn given to should be soaked ib.—should have access to slacked lime or some calcareous substance ib.—should not be scalded 291.
 Poor, Mr. Benjamin, his communication respecting the construction of bee hives 331.
 Powell, Col. John Hare, notice of his improvements in the breeds of cattle 135—his communications on mangel wurtzel and millet 276, 277.

- Prairy Dog, sketches of 303.
 Prescott, J. Esq. his remarks on the culture of mangel wurtzel 338.
 Preston, Samuel, his remarks on guaging 85—on grafting fruit trees 121—on clearing land 172—on the best mode of manufacturing maple sugar 182—on mill machinery, and the measure of water in mill-races 259—his communication respecting the workshop of Archimedes 306—on the strength and durability of timber 306, 354—best time of cutting do. 306—on the moon's influence on vegetation 370.
 Prince, John, Esq. his remarks on bad winter keeping of cows 84—his statement respecting agricultural productions 116—notice of his communication respecting insects in peach trees and other fruit trees 333.
 Proctor, J. W. Esq. his notice of agricultural experiments in Essex county 144.
 Pumpkins, recommended as food for horses 134—remarks on their cultivation 365.
 Putnam, Col. Jesse, description of his premium farm 324.

Q.

- Quincy, Hon. Josiah, description of his farm 2—his exposition of the faults of farmers, as respects the economy of barn yards and stercoraries 29.

R.

- Race Ox, an account of one 156.
 Radish, how cultivated 294.
 Rats and Mice, how extirpated 37.
 Rattle Snake, bite of, how cured 29.
 Receipts, Indian meal the best cosmetic for ladies complexion 3—infusion of elder leaves preserves against insects ib.—several different modes of making bread 4. for making yeast 5—substitute for yeast ib.—to prevent the bite of mosquitoes ib.—for making currant wine 6—to take the rancid taste from butter 12—to make butter from scalded cream ib.—for curing butter ib.—to fine and clarify beer ib.—several for making Ruta Baga puddings 12—for founder in horses 19—potatoe pudding 20—potatoe bread ib.—for cud lost by an ox or cow 21—for American Tokay 21—for destroying ants and spiders 26—for destroying crickets ib.—against vermin that infest swine ib.—for the bite of the rattle snake, or other venomous animal 29—for the cholera morbus ib.—for destroying white weed ib.—for destroying the Canada thistle 30—for the ague ib.—for a broken winded horse 35—several for preserving meats 37—for preserving cream 37—to prevent bottled cider from bursting 37—to prevent skippers in bacon 37—to extirpate rats and mice 37—for making cider ib.—for dysentery and bilious disorders 37—to make salt butter fresh 66—to cure tainted meat ib.—to preserve meat ib.—to destroy bed bugs ib.—to destroy the bee miller 67—to cure the croup 72—for making green grape wine 34—to make Champagne from grapes equal to foreign wine 91—for fattening hogs 113—to prevent bees being destroyed by the worm 108—to prevent cattle from disease in winter ib.—to render washing easy ib.—to preserve potatoes and fruit ib.—to prepare a pickle or brine for beef 110—to preserve eggs ib.—for preserving iron and steel from rust 115—for weaving mats ib.—for making jelly for calves 122—to make hay-tea for calves ib.—to make good butter from the milk of cows fed on turnips 123—for the scab in sheep 123—to preserve potatoes which are frozen 123—for pickling beef 130—my grand-mother's pickle 130—for a cement designed as paint for the roofs of houses 131—for breaking glass in any required direction 131—for making rice glue 139—to remove fruit stains or iron mould from linen or cotton cloths or other substances 141—antidote against contagion 141—substitute for yeast ib.—for preserving lemon juice, or lime ib.—for purifying putrid water ib.—for purifying glass vessels ib.—for freezing wells from fixed air ib.—the best mode of administering opium ib.—for preserving horses feet when ploughing among lime ib.—for the purification of fish-oil and vegetable oils 142—for salting meat ib.—for distinguishing a steel instrument from an iron one ib.—for damp in walls 148—for a dentifrice 148—for making Pomona wine ib.—of a varnish for iron or steel 149—for poison by the oxide of lead or copper 157—wine tests, or methods for ascertaining if there be lead or copper in wine or cider 157—for rice jelly 174—best cure for the gravel 224—for making soap by steam 226—for making cider oil, or

- cider royal 227, 254—for drying peaches 227—for preserving peaches 227—for preserving bacon ib.—to preserve woollen clothes &c. from moths ib.—for making Panama ib.—to increase the strength of vinegar 230—to revive old writings 230—to prevent wine from tasting of the cask 230—to clarify new wine ib.—to restore turned wine ib.—for the relief of cancer by iodine ib.—infallible for the cure of diarrhoea in calves 234—to prevent polished hard ware and castings from taking rust 235—to clear iron from rust 235—for making sausages 243—to make size from potatoes 248—to make cider royal and barley coffee 254—for making maple sugar 255—to make glue from leather 256—to cure sore eyes ib.—for saving cattle, sheep or hogs, choked with roots 258—a cement for cracks in stoves 270—preventives against fleas in hogs, lice in cattle, and ticks in sheep 270—to preserve bacon at all seasons, and in all places 275—to prevent smut in spring wheat 275—for seasoning glass 275—to stop cracks in glass vessels 282—a cement for preserving wood and brick ib.—cement for wood or paper ib.—for preserving vines from bugs 294—to obtain oil essential from flowers 299—to obtain oil or balsam of Gilead 299—to remove vermin from cattle 307—to mix mustard 309—to raise turkeys ib.—for swollen legs, or grease in horses 310—for making sage cheese 323—for restoring and rendering legible damaged parchment deeds, &c. ib.—for making good yellow butter 330—to dress flax so as to resemble silk ib.—to whiten straw ib.—for preserving strawberries ib.—for making hop beer ib.—for washing plaid stuffs, so that they may not shrink or loose their lustre 331—to prevent mortification 342—to prevent worms from breeding in the heads of sheep 342—against weevils 351—for the destruction of flies 355—for making sirup of sugar ib.—for making broth without meat ib.—for making a polishing powder from charcoal 356—for making yeast ib.—for preserving grain from mice ib.—for destroying caterpillars 362—to prevent fishing lines from rotting 363—for curing the gravel 368—for destroying caterpillars 371, 372—for making potatoe yeast 371—for preventing rust in wheat 379—for the whooping cough 390—to keep insects fruit from and vegetables 395—for the asthma ib.—composition to preserve wood 396—to preserve the roof of a house ib.—to sweeten meat and fish that is tainted 411—to purify fly blown meat 411—for sweetening the breath, &c. ib.

Remembrancer, farmer's and gardener's 278, 286, 292, 301, 309, 317, 325, 333, 341, 349, 357, 365, 373, 381, 389, 397, 405, 413.

Repository, Mass. Agricultural, notices of 1, 390.

Rice, Asa jun. his observations on raising and feeding cattle &c. 223—on raising corn ib.—notice of his large cattle 251.

Rising early, recommended 320.

Roller, an implement in agriculture, advantages of 78, 170.

Roots, how preserved 196—more profitable food for cattle than corn 234.

Roxbury Farmer, his remarks on the seasons 2. See further Farmer.

Ruta Baga, drill for sowing 67—cultivated as a second crop by Mr. Buel 246—David Little's statement relative to a crop of 340—Agricola's remarks on its cultivation 388—remarks on by Hon. Levi Lincoln 315.

Rye, should be sown between the middle of August and the middle of September 12.

S.

S. his remarks on destroying caterpillars 262.

Salt cloths, manufactured at Stoneham, near Boston 30.

Salsafy, or oyster plant, on the culture of 42, 43.

Salt said not to be a remedy in milldew 118—various modes of using it for neat cattle and other stock 414.

Scrapings of roads, useful for manure 28.

Secale, remarks on the culture of 42.

Sea-water, watering plants with, in certain cases recommended 357.

Seeds, best kinds of how raised 20—how to tell when sufficiently ripe 60, 293—soaking of when advisable 60—preserving of 61—should be sown with the fruit ib.—to generate the best kinds of ib.—selection of remarks on 112, 222—on the choice of 293—those that are good will sink in water ib.—steeping of with fruit-tying liquids not recommended 330—remarks on collecting 405—different kinds of but of a similar nature should not be raised near each other 405.

Sepulture, remarks on the dangers and duties of, a pamphlet reviewed by the editor 394.

Sheep, long-wooled and broad-tailed, from Africa, notice of 8, 34, 202—scab in, remedy for 123—fish of for ib.—Saxon, imported by Col. James Shepherd 205—number of in England and Wales ib.—disease 205—worms in head of 205, 342—for consumption 205—foot rot in ib.—on the attention they require the spring 301—long-wooled, imported by Capt. 1. notice of 351—remarkable increase of 390.

Shepherd, Thomas, Esq. his mode of raising corn ruta бага 116.

Sherwood, Aaron, sheared 18 lbs. wool from a single sheep 375.

Shoeing horses, new system of 142, 199.

Short horned cattle, breed of recommended 173.

Sick persons, notice of a machine for moving 360.

Silk manufactured by Mr. Jos. Reed, notice of 19.

Silliman, professor, notice of his experiments for obtaining diamond from charcoal 371.

Silver mines discovered in Missouri 383.

Sinclair, Sir John, his remarks on deep ploughing 6—letter to conferring a diploma 331.

Slavery, effects of in Missouri 314.

Smoke, antidote against contagion 176.

Smut in wheat, remedies for 103.

Soap, on the making of by steam 226.

Soap suds, as a manure, and an antidote against insects 333, 395.

Soil, the nature and constitution of 217.

Soils, improvement of 37—analysis of 94.

Sorrel destroyed by lime 12.

Spencer Washington, recommends wild carrot for gravel 368.

Spider, foretells the state of the weather 224.

Squashes, notice of very large ones raised by George Olney, Esq. 95—summer, 180 in number raised one seed 131.

Stables for horses, should not be too close 12—on construction of 27.

Staples, Mr. Daniel, his observations respecting the influence of the moon on vegetation 339.

Steam machine for conveying coal, notice of 139.

Steel instrument, how distinguished from an iron one 258.

Stevens, Henry, his remarks on the cultivation of 258.

Stones useful in some soils 393—on digging and dressing for wall 397.

Straw cutter, Safford's, notice of 279.

Strains and bruises in cattle 249.

Stubble, burning of, remarks on 6, 413.

Stubble fields, on the management of 413.

Subscriber, a, his query on the use of lime with a manure 306—on painting horses 314.

Sugar maple, how made 254.

Sunflower seed, and oil, notice of 148.

System in business, on the advantages of 300.

Swartwout, Samuel, his remarks on a flax dressing machine 322.

Swellings in the joints and bones of cattle 249.

Swine, should not be kept too warm 12—nor in fens 12—should not be full fed when first shut up fattening 12—should be supplied with dry rotten wood as an absorbent 12—remedies against the vermin which infest them 28—weight of, how ascertained—substitute for ringing of 61—breeding stock of 61 to be most profitable 61—notice of an excellent breed of 107—best fattened with acid food 113, 206—recommended in fattening 144—pasture for recommended 278—profitably fed on swamp brakes 371.

T.

T. his remarks on the fattening of cattle 234.

Tail sickness in cattle 257.

Tan or tanner's waste, may be useful as a manure 2.

Tanager, scarlet, a beautiful bird, remarks on 155.

Tea, hyson, cultivated in South Carolina 368, 403.

Teasels, on the cultivation and uses of 272.

Teeth, an essay on the preservation of 188.

Thistles, mode of destroying 398—see likewise Carl thistles.

Threshing machine, Pope's, notice of 302—Howe's, notice of 362—one used by the religious Society in Northbury, N. H. called Shakers 378.

Thorn, Virginia, not so valuable for making hedges as the English hawthorn, or the N. Eng. cock-pur thorn 2.

ber, on the best time of felling trees for 17, 18, 223.
 34, 250, 306—method of trying the goodness of 340.
 othy seed, how saved by Mr. Winchell 364.
 ay, American, receipt for making 21.
 -dressing, remarks on 278.
 id mill, remarks on 155.
 es in young plantations, how secured against rab-
 its, mice, &c. 123.
 well Lewis, his observations on constructing ovens
 as to save fuel, &c. 374.
 isian Sheep, Judge Peters' account of 34. *See fur-*
er, Sheep.
 tips, on the culture of, by Mr. Bud 106, 131—
 ry large 144—Messrs. Little's crops of 178, 179,
 32, 335—remarks on their culture 397.

U.

rs in cattle, remedy for 257.
 n Mr. notice of his plans for improving Salem alms
 use 130.

V.

ntine, Col. report of his premium crop 178.
 ish for iron or steel 149.
 rinary college, remarks on 181.

W.

is communication on salting hay 399.
 s, damp in, how prevented 148.
 ut shells, destroy insects which injure peach
 es 107.

Warts in cattle 249.
 Wash, sour for fattening swine 113, 206.
 Washing rendered easy 108.
 Water, how procured by boring 139—how ascertained
 to be wholesome, &c. 353.
 Watering plants, remarks on 357.
 Water spouts in Lake Erie 63.
 Webster George, on destroying caterpillars by sulphur
 introduced into trees 379.
 Weeds should be placed in compost heaps before their
 seeds ripen 227—on destroying them 365—how made
 useful 406.
 Welles, Hon. John, his remarks on a communication
 of a member of the Berkshire Agricultural Society
 166—his account of the weight and evaporation of
 grasses 235—his essay on forest trees 329—his com-
 munication respecting the draining of land, &c. 347
 —his remarks on orchards 372.
 Wells Mrs. received a premium for a bonnet 3.
 Wells with buckets preferred to pumps 120—how pu-
 rified from fixed air 141.
 Wheat, average crop of in England, in France, and in
 Pennsylvania 29—how prepared to prevent smut 103
 —on the cultivation of 132—by Payson Williams,
 Esq. 178—rust in, prevented by sowing a border
 with rye 379—weeding of recommended 365—har-
 vesting of 405.
 White weed, how destroyed 29.
 Wife, prayer of a young gentleman for 11—on the
 choice of 40.
 Williams Payson, Esq. report on his crop of spring
 wheat 178.

Willow, weeping, a great corrector of bad air 108—
 great advantages of planting in low boggy land 113.

 provements by the religious society called Shakers,
 in Canterbury, N. H. 377.
 Woad cultivated in Danvers 307—remarks on its cul-
 ture 386, 387.
 Wolcott Oliver, Governor of Connecticut, his letter on
 the preparation of flax 50.
 Wool, quantity of imported into the United States 30—
 —11 pounds of sheared from a merino buck 30—18
 pounds from one sheep, by Aaron Sherwood 375—
 how prepared for market in the neighborhood of Al-
 exandria 368—causes of the difference in price be-
 tween domestic and imported 396.
 Wood, on the growth of 302.
 Worms in gardens, observations on 46—in peach trees
 and locust trees ib.—that destroy grass and corn 61,
 67—in the head of sheep 205, 342—in fruit trees 333.
 Wounds, in cattle, how treated 233.

Y.

Yeast, a receipt for making 5—a substitute for ib.
 Yellow fever imputed to animalcule 53.
 Young Arthur, his observations on ploughing 60.
 Young John, Esq. his report delivered before the Nova
 Scotia Provincial Society 337, 345.

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHIFARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I.

BOSTON, SATURDAY, AUGUST 3, 1822.

No. 1.

PROSPECTUS OF THE NEW ENGLAND FARMER.

AGRICULTURE, within a few years, has been improved with a rapidity without precedent in the annals of art; and new discoveries and processes, in its various branches, are still in a train of successful developement. These improvements are of paramount importance, not only to the practical farmer, but to the whole community. Every human being has an interest in that art which is the foundation of all other arts, and the basis of all civilization.

Skill as well as industry is at least as requisite in agriculture, as in any of the finer but less useful arts. The head must direct the hand of husbandry; and in cultivating the earth, the most incessant toil, without the guidance of knowledge, and the superintendence of intellect, is of little avail. The science of agriculture is in a great degree founded on experience. It is therefore of consequence that every farmer should know what has been done, and what is doing by others engaged in the same occupation, and that he should impart to others the fruits of his own experiments and observations. Knowledge of this description can in no way be so cheaply, beneficially and generally diffused as by newspapers chiefly devoted to those topics which are particularly and appropriately interesting to the cultivators of the soil.

Publications of this kind have been found to be of great utility in Europe and in the United States. The *American Farmer*, at Baltimore, and the *Plough Boy*, at Albany, ably conducted and liberally patronized agricultural papers, have rendered services to the country which are generally and highly appreciated. Those papers, however, cannot be so conveniently circulated in New England as a similar publication might if printed in its Metropolis. Besides, the matter contained in those papers is not always adapted to the soil and climate of the Eastern States; and communications proper for an agricultural paper cannot be transmitted several hundreds of miles without more delay, risque and expense, than most are willing to encounter, with no other remuneration than a prospect of benefit to the public.

The NEW ENGLAND FARMER will be edited by a gentleman of science, conversant with the practice as well as the theory of husbandry.—The proprietor has likewise been promised the assistance of several gentlemen who have been distinguished for successful experiments and able essays calculated to improve the agriculture of New England.

Although this paper will be principally devoted to Agriculture, it will likewise contain a concise summary of news, and sketches of topics common to newspapers in general. Indeed, as a mere vehicle of intelligence, without reference to its agricultural contents, it is presumed it will prove more useful to country subscribers than those papers which are nearly filled with ship news, mercantile advertisements, &c. of little or no value to those who live at a distance from our sea-ports. And the proprietor engages

that no more than one fourth part of his paper shall, in any case, be filled with advertisements; and in general a still smaller portion of it will be occupied by advertising customers. Party politics, and polemical divinity shall be likewise absolutely excluded from the columns of the New England Farmer.

Massachusetts Agricultural Repository and Journal.

We know of no publication so well deserving of liberal patronage and general diffusion among an agricultural community, as the above named. We have turned over the leaves of many works of a similar nature issued on either side of the Atlantic, but have seen none, which we think contains, in proportion to its quantity of matter, so much to be remembered and practised upon as the subject of this notice. Some foreign journals which we have seen, contain articles more elaborately written, but at the same time they are generally more speculative, and less useful. Good Sense, Science and Agricultural Experience are exhibited in every number of the Massachusetts Journal, and by their union give results, which cannot fail to benefit that portion of an enlightened community for whose use they are more immediately intended.

We shall not attempt to write a review of this Journal, but merely to give such notices of its contents, as we hope may induce such of our subscribers as are not in possession of its numbers to procure them for their own benefit, as well as to assist in the diffusion of the most useful kind of useful knowledge for the benefit of the public.

The number for June, 1822, commences with "*Remarks on the manner in which this Journal is conducted, and the rules by which the committee entrusted with the publication are governed.*" By J. L. one of that Committee." We shall here give some extracts from this paper, which appear to us of general importance, though made with reference to a particular subject.

"The Committee appointed for the publication of the Journal do not consider themselves as in any degree responsible for the correctness of the statements, or the soundness of the theories of the various writers, whose essays they publish. Their rule is to admit every essay, which appears to contain any new hint in relation either to Agriculture or Horticulture. It is manifestly impossible for them to judge of the correctness in point of fact, of any statement made by a correspondent, and they have believed, that a more free and unreserved communication of all Agricultural experiments, whether the conclusions drawn from them are erroneous or not, is of great use. The cautious farmer, if he is struck with their novelty, may try them for himself," &c.

"It is true that with respect to many subjects intimately connected with the prosperity of our agriculture, our Journal during the last thirty years has contained a great number of opposite, and irreconcilable opinions. But this ought not to diminish the public confidence, since it is avowed to be conducted on the principles of free enquiry, and since it is not more liable to this objection than all similar works, published in this or in the European world. Men of science are found to differ on most essential points. How many theories have been published, have

prevailed for a time, and have gone into oblivion in the important science of medicine! How materially has chemical science changed, not only since the time of Priestly and Black, but since it was supposed to be irrevocably fixed by Lavoisier and the French chemists of his school! How great are the divisions of theoretical opinion among the Geologists, the Wernerians and Huttonians!"

We give the preceding with a view in part to solicit the indulgence of the reader, should our Journal, (as it doubtless will,) exhibit opposite theories and clashing opinions. Light is often elicited by the collision of opaque bodies, and the publication of erroneous theories, will sometimes lead to their refutation and the consequent developement of important principles in science, and the discovery of useful processes in art.

Notwithstanding, however, the difference of opinion, and mutable practices of modern agriculturists, Agriculture on the whole is rapidly improving. Mr. Lowell, observes, "We undertake to say, that thirty years since it would have been believed impossible to raise, as Mr. Hume well of Newton did 112 bushels of Indian Corn to an acre—and I distinctly recollect that when the first accounts in the Bath agricultural papers reached us that they had raised 500 and even 900 bushels of potatoes per acre, it was deemed, if not a fable, yet an experiment peculiar to Great Britain and its soil and climate and not to be looked for among us."

"Still we have seen that in all parts of our country individuals have succeeded in raising from 450 to 500 bushels per acre of this invaluable root. We have seen that the cultivation of other roots to aid the support of cattle during the winter has advanced much faster with us, considering the late period in which we undertook it than in any part of Europe. We hear, not occasionally but constantly, every year, of 600 or 700 bushels of Mangel Wurtzel, or the white beet—of 500 bushels of the Ruta baga or Swedish turnip per acre, and our cattle are and must be of course better fed, and eventually highly improved."

The improvements in the different breeds of cattle, which have been the results of modern husbandry are not less remarkable than the increase of crops. A friend has informed us that "In the Picture of London, for the present year, it is stated, that about the year 1700, the average weight of oxen, killed for the London market was 370 lbs; of calves 50 lbs; of sheep 25 lbs; and of lambs 18 lbs. The average weight at present is, of oxen 600 lbs; calves 140 lbs; sheep 30 lbs; and lambs 50." Could a comparison be made between the present average weight of cattle and sheep, sold in our market, and the average weight of the same sorts sold 40 years since, we believe the improvement would be visible and striking. Still, much remains to be learned in the art of breeding and fattening cattle, and every step facilitates further progress to a degree of ultimate perfection of which at present we form no adequate idea.

The writer of the article alluded to is of opinion that it is better economy to plant at least middle sized potatoes, or cut potatoes, equal in size to those than either to use for planting small potatoes, or to cut the large potatoes into small parts, to scoop out the eyes, or take only the sprouts. The Hon. Josiah Quincy in a letter, published in the Massachusetts Agricultural Re-

pository, vol. v. p. 64, give the details of an experiment with cat potatoes, and whole potatoes planted in the same field, in adjoining rows, which resulted greatly in favor of the whole potatoes. In this case it appears that fact and theory coincide, for, as Mr. Lowell well observes "the potatoe is by nature formed to furnish from its fleshy and watery root the food for the young shoots." It is doubtless the juice of the planted potatoe which enables the young plant to endure early drought better than most other articles of field culture, while a late drought, which assails them after the paternal root has parted with its supply of nourishment proves very injurious to the crop.

Adverting incidentally to Hedge Fences, Mr. Lowell has the following remarks:

"When the Hon. Mr. Quincy published his experiments on Hedge planting for fences they [the Trustees] were aware that it would not be of much value except on farms destitute like his of natural materials for stone walls. In the sandy territory of the old Colony it may be of extensive use, but on farms such as I know, where the rocks must be got out before the plough can move; where they must be carted to a great distance if not used for walls, where, in short, walls are the cheapest mode of disposing of the stones, it is excellent husbandry so to apply them."

"In relation to the species of thorn recommended by Mr. Quincy, truth and long experience enable and require me to say, that the Virginia thorn so much recommended by Mr. Quincy, from whose account Mr. Quincy very properly introduced and recommended it, is not by any means the best adapted for general use, for quick or live hedges. It is too apt to run up, and not sufficiently prone to throw out strong lateral shoots, and it is believed, that either the common White Hawthorn of England, or even our own New England Cockspur thorn is better adapted for this purpose. We make these remarks not with a view of diminishing the merit of Mr. Quincy in making these experiments, and communicating them, but simply to make it known, that what we publish is intended merely as hints which others may follow or pursue, and we feel bound to state from time to time, any doubts which may occur to us on the subject, or any opposite experience."

"We have been more free in speaking of the limited extent to which thorn hedges can be carried in the stony and rocky country of New England, and the defects of the variety of the thorn first introduced because we are ready to say, and say it cordially, that we think all that portion of our country, which resembles the estate of Mr. Quincy, such as a part of Essex, Middlesex, Plymouth, Bristol, and some of the lands on Connecticut river will finally derive great benefit from the introduction of live fences. They are yet in their infancy, and to Mr. Quincy we owe their introduction. It will be many years before they will be extensively used, but they will we presume eventually be introduced in all countries where stones cannot be found, and he will I trust have the credit of introducing them, a credit which will increase as they shall be extended. They are very beautiful. They give an air of cultivation to the landscape—they shelter the crops, and produce a general effect of which no man, who has not seen the difference between French and English scenery can have any adequate conception."

(TO BE CONTINUED)

From the Mass. Agricultural Repository for June.

Comparison of the present with some past seasons.

We have for several years published such a comparison, and farmers and general readers having expressed a certain degree of pleasure from the statement we continue it. It certainly may be made of some use, if cultivators, instead of consulting the Almanack, will attend to the indications of nature. Certain plants will not flower till the earth has arrived at a given degree of temperature.

They vary from five to twenty days in the time of flowering in different seasons. If, therefore, as to the tenderer plants, the Indian corn, squash, pumpkin and melon, we should resolve to plant them, not at a determinate period of the year, but when we should find by the flowering of certain plants, that the soil is so warm as to endanger their rotting in the earth, we think some good would be attained.

We shall take a few plants as a specimen, and compare the present season with some of the earliest during the last nine years.

The Cherry opened its blossoms in 1813, May 10th—1815, May 10th—1816, May 6th—1817, May 17th—1820, May 2d—1822, May 1st.

Asparagus was fit for the table for the first time in 1813, May 14th—1815, May 6th—1816, May 5th—1817, May 15—1820, May 1st—1822, May 1st. It should be remarked that the Asparagus was cut from the same bed in each year—a bed was planted 33 years since, and never changed, and one which has been constantly growing better—an important fact in horticulture.

Plums were first in flower in the year 1815, May 14th—1817, May 7th—1819, May 13th—1821, May 11th—1822, May 4th.

Pears began to blow for the first time in 1813, May 20th—1815, May 12th—1817, May 7th—1819, May 17th—1820, May 9th—1822, May 5th.

Apples first showed their open flowers, in 1813, May 23d—1816, May 13th—1817, May 12th—1819, May 19th—1820, May 11th—1822, May 9th.

It will be seen by this table, that the present season is the earliest on the whole which we have had for nine years.

There is, however, a manifest difference between the relative times of flowering of the different plants in the several years: and this is readily accounted for by the circumstance, that a single turn of cold weather will check the progress of all plants, and the season which may have produced the earliest flowers on the Apricot, the earliest of our fruits, may not be earlier than usual in producing flowers on the Apple.

To give one practical rule which we believe may be of some use, we should say, that when the Apple tree flowers we may safely (be it sooner or later) venture to put our corn, squashes and melons into the earth.

This season was the earliest as to the opening of the ground known on my place for 16 years. I planted potatoes and peas on the 7th of March, fifteen days earlier than I was ever able to do it before—but as I have often before remarked, all these differences disappear as the season advances, and on the whole I doubt whether the present season is in advance more than four or five days of that of common years. It however has been a great relief to the labor of the farmer—the season of labor has been ex-

tended this year at least three weeks in this vicinity, and this is of great value to him. The show of blossoms in all kinds of fruit is very good, nearly double to that of the last year.—The present cool weather is highly beneficial to the fruit. We had a very severe frost on the 6th inst. which in low grounds injured early potatoes, but the damage on the whole was not great. If we can escape another for one week more, we may presume on a fruitful year. The prospect of grass is at this moment above that of ordinary years.

A ROXBURY FARMER.

From the New England Galaxy.

JUDGE QUINCY'S FARM.—We have heard that Mr. Quincy was a practical as well as theoretical farmer, and it is well known that his talents have been industriously employed in raising the standard of agricultural excellence in the neighborhood of Boston, but we do not recollect to have seen any description of his farm, or his mode of cultivating it, till the following, for which we are indebted to Mr. Stone's "Extracts from a Gentleman's Port Folio."

Judge Quincy, in addition to his professional duties, is a theoretical and practical farmer; and I have taken the liberty of introducing the name of this distinguished gentleman because there is a part of his system which was entirely novel to me, and which I think should be more extensively known, as I feel persuaded that many of our agriculturalists may profit by it. His farm is extensive and surrounded by a flourishing hawthorn hedge; but there is not an interior fence on the premises. The whole presents a single field, devoted to all the various purposes of agriculture. No part of it is allotted to pasture, as his cattle are fed in their stalls, and never suffered to run in the field. The advantages of this system are thus given: Formerly there were seven miles of interior fences to be kept in repair, and by keeping the cattle up, the whole of this expense is saved. Formerly sixty acres of this farm, were devoted to pasturage; but now a greater number of cattle by one third, are kept upon the products of twenty acres; and I never saw cattle in better case. The saving by this means is enormous, and that immense advantages arise from it, is too apparent to be dwelt upon. During the summer the cattle are fed upon grass, green oats or barley, cut up the day previously, and suffered to wilt in the sun; and the manure, which is thus saved, will more than pay for the extra trouble and expense. The farm is highly cultivated, and every kind of grain and vegetables grown in the country, appeared to have a place. The cultivation of carrots it was said was found very profitable, and, I passed a lot of five acres.—Near this were also several acres of cabbages, ruta baga, mangel wurzel, millet, &c. &c.—Judge Q. has also an extensive salt manufactory, of 175 cisterns or vats, which, however, he contemplates soon to enlarge. The salt water is pumped by wind, and is let off from one vat to another—first depositing the sediment, and then the sulphate or carbonate of lime, until it becomes pure, when it is suffered to stand and evaporate by the heat of the sun. The crystallizations form on the top and settle to the bottom. I have preserved a beautiful specimen. One man attends the whole of this concern.—The residence of Judge Q. is a charming situation. The house is a neat and spacious building, and the grounds, varied in surface and scenery,

From the American Farmer.

SKIPPERS IN BACON, give much trouble to housewives in the country.

It has been discovered, by a female correspondent in the country, from whom we have received several useful communications, that skippers in bacon may be effectually and speedily destroyed by the use of *elder juice*, but the exact manner of preparing and applying it, are not described. This ought always to be done in giving receipts—the field is yet open for numberless useful discoveries in all the departments of rural and domestic economy.

Since writing the above, we have the following more particular account from our esteemed correspondent :

“Last year we lost at least one third of our ham meat, by the skippers, notwithstanding every attention, but never destroyed the skippers while the meat lasted. Our neighbours were, in this respect, as unfortunate as ourselves.

“This spring, knowing that our meat had been well smoked, and the weather being dry, we neglected airing it as customary, until our old enemy the skipper returned, and had eaten it smartly. Sister, who attends to it had it examined, scraped and sunned; (no one can be more particular.) In a week after, she had it examined and found that there were nearly as many skippers as at first: you may suppose, after the loss we suffered last year, we were very anxious to destroy this troublesome insect. I had known for many years, that elder juice would destroy maggots. If a hog, sheep, or any other animal gets wounded, and the flies get to the wound, they will create maggots; by washing the wound with elder juice, they will roll out by hundreds, if there be so many in it. I proposed therefore to try it on our bacon. The leaves were accordingly beat in a mortar, adding a little water; the flesh side of the meat was rubbed with the leaves thus bruised, and in three weeks after, the meat was re-examined, and the skippers utterly destroyed. The application here described, does not in the least degree communicate any bad taste to the meat. I have little doubt, that this, with many other simple applications within the reach of every housekeeper, might be applied to many other useful purposes, if proper pains were taken to make the trial. If such homely communications, on such homely subjects, are admissible in the *American Farmer*, you can publish what I have written, as you know you can depend on its accuracy, and I shall be amply paid for my trouble by what I know I shall receive, the thanks of many

A HOUSEKEEPER.

We believe that the virtues of elder are less known and appreciated than they ought to be. Mr. Deane's Geographical Dictionary states that Christopher Gullet, Esq. had made some experiments, which were communicated to the Royal Society, of which the following is a brief account :

“He whipt calbages gently with green boughs of elder, just at the time when the butterflies appeared, after which, though they hovered over them, they were never observed to touch them. He whipt the limbs of a plumb tree as high as he could reach. That part remained green and flourishing; but all above shrivelled up, and was full of worms. He concluded that if a tree were sprinkled with an infusion of elder, once a week or fortnight, it would effectually preserve it without injuring the tree or the fruit. He prevented the yellows in wheat, which is caused by an insect, by

brushing the wheat with elder; and preserved a bed of young cauliflowers. He prefers the dwarf elder as it emits the strongest effluvia.

“Perhaps, it may be found, as this writer suggests, to preserve turnips from the fly, and these and other plants from grass-hoppers and all other insects.”

A friend of the Editor, stated to us that he had used an infusion of elder leaves as a preservative against the small yellowish bugs, which infest cucumber vines, squash vines, &c. and he believes with complete success, as the bugs ceased to devour the plants from the time the infusion was applied. It was rather late in the season, however, before the application was made, and it is possible that the bugs had finished their year's work of mischief before they were disturbed by the elder infusion. We hope that further trials will be made.

Carelessness.—Negligent masters and mistresses are considered as lawful prey by their domesticities; and those who are proverbially easy in the management of pecuniary and economical concerns, are at once cheated and despised for a disposition, which, however it may engage the affection and esteem of candid and enlightened characters, seldom fails to excite the rapacity of those who are possessed of it.

That low cunning, which in fools supplies,
And amply too, the place of being wise.

A man who had been a zealous partizan, in politics, but had shifted his course so often that he sometimes strayed so far from the lines of demarcation which separated one party from another that he could not always say which side he belonged to, was asked, what made him turn his coat so often? He replied that “one good turn deserves another.”

Gunpowder and Brandy.—An office in the government of Satan, being once upon a time vacant, “the prince of the power of the air,” convened a counsel, when it was proposed, that on the trial of the skill and abilities of the two demons, he who caused the most misery on earth and brought the greatest number of mortals to the regions of despair, should fill the vacant office and be first in authority.

One went in the shape of *Gunpowder*, the other that of *brandy, rum, gin, &c.* the former was an open enemy and roared with a terrible noise. This made the folks to be afraid, and put them on their guard. But the other passed as a friend and a physician, pretended to make them strong and healthy, was at all the merry makings, frolics and entertainments. By these means he caused them to be off their guard; and at length to become his most willing servants, and that too, “for the wages of death.” Under the “notion” of helping digestion, comforting the spirits, and cheering the heart, he produced the direct contrary effects.—And, having insensibly thrown great numbers into a fatal decay, he was found to people hell and the grave so fast, as to merit the office, in preference to him who went among the people in the shape of gunpowder.

Last week a young man with a slight obstruction in his speech, came into our office to purchase a book—the price happening to be a few pence beyond his means, we told him we would furnish him with a copy a little torn. Not finding one, however, as we expected, he very honestly remarked, that “we might tell tear another.” The joke was certainly worth something, and we instantly furnished him with a *whole* copy.—*Nantucket Inquirer.*

From the Hampshire Gazette.

Sweet Corn.—A writer in the Plymouth paper asserts that sweet corn was not known in New England, until a gentleman of that place, who was in Gen. Sullivan's expedition against the Indians in 1779, brought a few ears to Plymouth, which he found among the Indians on the borders of the Susquehanna. This writer says that if the ears are picked from the stalks for seed, the produce will assimilate to our common corn, but if the seed ears be selected from the suckers, the corn will not lose its peculiar qualities.

Cotton.—Several experiments are now making in New York and Connecticut, to ascertain whether cotton can be raised in this northern climate. Some plants in Albany are now in blossom.

A Cosmetic for ladies complexions, said to be superior to all other washes.—Put over the fire a pint of water, and when it boils stir in fine Indian meal enough to make it a paste; let the ladies use this paste instead of soap every time they wash themselves. If a spoonful of honey and a little rose water are stirred into it when cooling, it will be still better.

Lightning.—Wet clothes are good conductors of lightning, and if a flash in its way to the ground, should strike a person's head, whose clothes are wet, it will run in the wet clothes over the surface of the body, whereas if the clothes were dry, it would go through the body and occasion death.

It is stated in a London paper of 30th May, that among the rewards presented the day before by the society for the encouragement of manufactures, &c. was “the large silver medal and twenty guineas,” to Mrs. Wells, of Weatherfield, Conn. for her imitation Leghorns.

From the Boston Gazette.

Copperas water is a cheap and certain destruction to bugs, which cannot be too generally known.

It is said, that if horses be rubbed down with chesnut-tree leaves, in the morning, they will not be annoyed by flies during the day.

United States' Lead Mines.—A notice from the War Department is published in the western papers, offering to receive proposals, at the office of the Ordnance Department, for leasing any of the lands of the U. States containing mines of lead, upon an annual rent of one tenth of the product of the mines, to be deposited, in pure lead, in a store-house on the ground. The leases not to be for more than three years, and not for a quantity of land to any individual or company, exceeding three hundred and twenty acres, &c. Leases may be renewed at the expiration of three years, at the option of the government, reserving the right to raise the rent, but not to a higher rent than one fifth of the product. The advertisement is dated at the Ordnance Department, June 15th.

BREAD.

There is, perhaps, no subject connected with Domestic Economy of more importance than the manufacture of Bread. We have therefore thought it might prove acceptable to our readers to present them with some recipes for composing the *Staff of Life*; and should any of our friends or patrons be in possession of any better methods of answering the same purpose, they will oblige us, and, we hope, do the public a service by communicating them for publication in our paper.

I. To a peck of flour add a handful of salt, a pint of yeast, and three quarts of water: the whole, being kneaded in a bowl or trough will rise in about an hour; it is then moulded into loaves, and put into the oven. For French bread, they take half a bushel of fine flour, ten eggs, and a pound and a half of fresh butter, into which they put the same quantity of yeast, and tempering the whole mass with new milk pretty hot, leave it half an hour to rise, after which they make it into loaves or rolls, and wash it over with an egg beaten with milk: care is taken that the oven be not too hot.

II. Potatoes, mixed in various quantities with flour, make a wholesome, nutritive, and pleasant bread. Kliogg, who has been styled the rustic Socrates, recommends, that potatoes well boiled and carefully peeled, should be put into a kneading trough, covered with boiling water, and bruised till they be converted into a kind of soup of equal consistence throughout. A half, a third, or a fourth, of this soup, mixed with the flour of wheat, makes a bread of an excellent taste, and extremely salutary and nutritive.

III. M. Dudit de Maizieres, a French officer of the king's household, invented and practised with the greatest success, a method of making bread of common apples, very far superior to potatoe bread. After having boiled one third of peeled apples, he bruised them while quite warm, into two thirds of flour, including the quantity of leaven, and kneaded the whole without water, the juice of the fruit being quite sufficient. When this mixture had acquired the consistency of paste, he put it into a vessel in which he allowed it to rise for about twelve hours. By this process he obtained a very sweet bread, full of eyes, and extremely light.

IV. At Debritzin, in Hungary, excellent bread is made by the following process without yeast: Two large handfuls of hops are boiled in four quarts of water; this is poured upon as much wheaten bran as it will moisten, and to this are added four or five pounds of leaven. When the mass is warm, the several ingredients are worked together till well mixed. It is then deposited in a warm place for twenty four hours, and afterwards divided into small pieces about the size of a hen's egg, which are dried by being placed upon a board, and exposed to a dry air, but not to the sun; when dry they are laid up for use, and may be kept half a year. The ferment, thus prepared, is applied in the following manner: For baking six large loaves, six good handfuls of these balls are dissolved in seven or eight quarts of warm water; this water is poured through a sieve into one end of the bread trough, and after it three quarts of warm water; the remaining mass being well pressed out. The liquor is mixed with flour, sufficient to form a mass of the size of a large loaf; this is strewn over with flour; the sieve

with its contents, is put upon it, and the whole is covered up warm, and left till it has risen enough, and its surface has begun to crack: this forms the leaven. Fifteen quarts of warm water, in which six handfuls of salt have been dissolved, are then poured upon it through the sieve; the necessary quantity of flour is added, and mixed and kneaded with the leaven; this is covered up warm, and left for about half an hour; it is then formed into loaves, which are kept for another half hour in a warm room; and after that they are put into an oven, where they remain two or three hours, according to their size. One great advantage attends this kind of ferment, that it may be made in large quantities at a time, and kept for use; and, on this account, it might be convenient on board of ships, or in camps for armies in the field.

V. The carbonate of magnesia, [common magnesia of the shops] when well mixed with new flour, in the proportion of from 20 to 40 grains to a pound of flour materially improves it for the purpose of making bread. Loaves, made with the addition of the carbonate of magnesia rise well in the oven; and after being baked the bread is light and spongy, has a good taste, and keeps well. In cases where the new flour is of an indifferent quality from 20 to 30 grains of magnesia to a pound of flour will considerably improve the bread. When the flour is of the worst quality 40 grains to a pound of flour is necessary to produce the same effect. As the improvement of the bread depends upon the magnesia, it is necessary that care should be taken to mix it intimately with the flour previous to making the dough. A pound of carbonate of magnesia would be sufficient to mix with two hundred and fifty six pounds of new flour at the rate of 30 grains to a pound.

VI. To every five pounds of flour add one pound of rice that has been previously boiled to a jelly over a slow fire; then, when luke warm, add your usual quantity of yeast, and make up your bread. Should you judge your jelly to be too thick add luke warm water; a method by which thirty pounds of flour and six of rice produce eighteen loaves, each four pounds and an half weight. Five pounds of flour produce eight pounds of bread; but with the addition of a pound of rice twelve and an half.

VII. In order to make bread of turnips the following method is recommended in the "*Museum rusticum commerciale*," an English work. When turnips are plentiful, a number of them should be pulled, washed clean, pared and boiled. When they are soft enough for being mashed, the greatest part of the water should be pressed out of them, and they should then be mixed with an equal quantity in weight of coarse wheat meal. The dough may then be made in the usual manner, with yeast or barm, salt, water, &c. It will rise well in the trough; and after being well kneaded, it may be formed into loaves, and put into the oven to be baked. The person who made this experiment had other bread made with common meal in the ordinary method. The turnip bread was baked rather longer than the other. When they were drawn from the oven, a loaf of each sort was cut; and upon examination, the turnip bread was sweeter than the other, not less light and white, with a slight, but not disagreeable taste of the turnip. When it was tasted twelve

hours after, this taste was scarcely perceptible, and the smell was quite gone off. After an interval of twenty-four hours, it could not be known that it had any turnips in its composition, although it still had a peculiar sweetish taste. After twenty-four hours, it appeared to be rather superior to bread made only of wheat flour; it was fresher and moister; and after a week it was still very good.

VIII. When wheat has grown or germinated, before it is ground, as often happens in wet seasons, magnesia, soda or some other alkaline substance seems indispensable to make good bread. An English writer in the Lancaster Gazette, 1816, mentions his having tried the following mixtures with flour from wheat which had germinated, which, if used without the alkali took twice the usual time, and when baked became a hard thick crust, elevated like a roof over a glutinous saccharine paste, the specific gravity of which was greater than water.

1st. Take new flour, two pounds; soda two drachms.

2d. Take new flour, two pounds; soda one drachm.

3d. Take new flour, three pounds; old do. one pound; soda two drachms.

4th. Take new flour, three pounds; old do. one pound; ground rice, half a pound; soda two drachms.

5th. Take new flour, two pounds; old do. one pound and an half; soda one drachm.

The soda was dissolved in the water in which the flour was to be mixed, and the yeast added in the usual way.

RESULTS.

Nos. 1 and 2 were pleasant tasted bread, similar to brown bread; it was friable, very buoyant in water, and filled like a sponge; it gained nearly one third, but No. 2 was better bread than No. 1; and this is well worth attending to, since it proves that with this flour half the quantity of soda produced the best effect, a circumstance that is of importance in an economical point of view.

No. 3 was better bread than Nos. 1 and 2, and it was but little inferior to the bread procured from our old flour, when the alkali was not used.

No. 4 was heavier than the preceding, but was baked in a tin pan.

No. 5 was also baked in a tin; it was as good bread as that made wholly with the old flour; but it was not very easy to distinguish Nos. 3, 4 and 5, from each other.

From these experiments it appears that by thirty grains of soda, a pound of the new flour, which as loaf bread would not otherwise be eatable, will make about a pound and an half of very pleasant tasted wholesome loaf bread.

REMARKS ON THE FOREGOING.

The four first of the foregoing recipes were taken from the Edinburgh Encyclopædia. The fifth has been proved by an experiment made within the knowledge of the Editor, to be useful. The sixth, seventh and eighth rest upon newspaper authority only. Perhaps it might be well to mix flour from new, or damaged wheat, with lime water, as a substitute for soda or the other alkaline substances mentioned above. The expense of lime water would be very trifling, as lime requires no less than 700 times its weight of water to effect its entire solution, and a single handful of quick lime thrown into a barrel of water, or any less quantity

which may be wanted, will be sufficient. It will require some hours for lime water, thus prepared, to settle, so as to become sufficiently clear for use, when should be carefully poured from the sediment. We do not pretend to vouch for the efficacy of lime-water thus prepared, and made use of. We merely suggest the thing as worth an experiment.

YEAST.

The following methods of making Yeast have been recommended, but we have never known their efficacy tested by actual experiment.

Take a quantity of hops suitable to the quantity of yeast you intend to make, boil them well, and strain off the water in which they are boiled; into this water stir a suitable quantity of sugar, and considerable salt, and then add to this proportionate quantity of good yeast; let this mass rise as much as it will; then stir in fine Indian meal till it is so thick that it can be made to small cakes of the size of a dollar or larger. When the cakes are thus made, dry them in the sun till they are hard, minding to turn them frequently to prevent their moulding, and then dry them by, in a dry place, for use.

When you wish to have yeast, take one of these cakes, crumble it to pieces, pour warm water on it, and let it stand in a warm place, and it will soon rise sufficiently to make good yeast. A quantity of these cakes may be thus made at once, which will last for six months more.

Art of making Yeast with Peas in Persia.

Take a small tea cup or wine glass full of it or bruised peas, pour on them a pint of boiling water, and set the whole in a vessel all night on the hearth, or in any other warm place; this water will be a good yeast, and give a froth on its top the next morning. In a cold climate, especially in a cold season, it would stand longer to ferment; perhaps twenty or forty-eight hours. The above quantity, says Mr. Eaton, made for me as much bread as half a quarter loaf, the quality of which was very good and light. It may be necessary that, in this country in winter it should be put to ferment in a cool oven.

Substitute for Yeast.

A patent was granted, in England, to Mr. Richard Lyster Blunt for his new invented composition to be used instead of Yeast. The substance of the specification, according to the Repertory of Arts, is as follows: To make a yeast gallon of the above mentioned composition, containing eight beer quarts, add in common water eight pounds of potatoes for eating; bruise them perfectly smooth, and mix with them whilst warm, two ounces of treacle, or any other sweet substance, and one quart (being the eighth part of a gallon of yeast) common yeast. And, for making bread, mix six beer pints of the above composition with a bushel of flour, using warm water in making bread; the water to be warmer in winter. Let the composition to be used in a few hours after it is made; and as soon as the sponge (the structure of the composition with the flour) begins to fall the first time, the bread should be made, and put into the oven.

MUSQUETOEES.

To prevent the bite of Musquetoes, rub the face with pennyroyal, a little weakened on the hands and face.

FACTS AND OBSERVATIONS RELATING TO

Agriculture and Domestic Economy.

Under this head, we propose, from time to time, to publish such articles, relating to agriculture and rural economy, as we may be of opinion will prove useful. Some of our statements will not, probably, be new to many of our readers, and others, perhaps, will not be found correct. But those to whom our observations may not convey new ideas, will, we hope, endure them for the sake of the benefits which may accrue to such persons as are destitute of the information they contain, which will be in part derived from writers of acknowledged merit and standard authority. Should our assertions or theories be found erroneous, we should be happy to stand corrected by our friends and correspondents. Our statements may, at least, suggest hints and processes which may lead to valuable improvements. And, as happily expressed in the last No. of the Massachusetts Agricultural Repository, "the cautious farmer, if he is struck with their novelty, may try them for himself. If they are found to fail, he will not repeat the experiment, but he will be very careful to inquire, whether he has faithfully followed the instructions of the first essayist. Whether the soil was the same as that in which the experiment was made, and whether he has taken the same pains to produce the proposed result. If he is satisfied that he has done, and that the novelty recommended is not entitled to his confidence, he will abandon it."

POTATOES

May be spoiled by bad management in harvesting. They should be dug in cool overcast weather, and picked immediately after the hoe free from sun and air, and kept moist with much dirt about them. If dug in fine weather, and they remain exposed to the sun, they will sweat in the summer, and be soft, waxy and strong. By lying to dry in the sun, they turn green, become in a degree poisonous, operate as physic of a purgative nature, and, it is said, sometimes prove fatal.

In gathering a crop of potatoes it has been recommended to run furrows on each side of the rows, and then a pretty deep one in the middle, which turns up most of the roots to the surface. A fork, with four prongs, with the addition of what may be called a fulcrum, fastened by a pivot to the back part of the handle may be used for raising the potatoes, not turned by the plough.

In the report on the agriculture of the county of Hereford, drawn up for the British Board of Agriculture, is a description of an excellent implement, invented by Mr. Yeldall, for taking up potatoes, having four prongs, or barbs of iron, with a fang, in the form of a double mould board, drawn by three horses or four oxen. It enters the ground, under the bed of potatoes, and throws them to the surface.

In feeding stock on potatoes it is best to steam, boil, or bake them. Sir John Sinclair, a famous English Agriculturist, (who, we believe, has corresponded with Gen. Washington on subjects of rural economy,) in his celebrated Code of Agriculture, asserts, that "there is something injurious in the juice of the potatoe in a raw state, which cooking eradicates, or greatly dispels."

We have, however, heard it asserted by farmers that raw potatoes, given, in moderate quantities to working oxen in the spring of the year answer a valuable purpose. They are

said to prove cooling, and opening, and serve at once for food and physic. Where cattle are fed in part on Indian corn or meal, which is in some degree astringent and heating, raw potatoes given occasionally, we have been told, promote the health, and add to the appetite of the animals.

The Farmer's Assistant says, "We never should advise to feed milch-cows with potatoes, either boiled or raw; as we have frequently known cows to be greatly lessened in their quantity of milk, by being fed on this root."

POULTRY.

Mr. Wakefield, a spirited farmer near Liverpool, says the compilers of "The Complete Grazer," keeps a large stock of poultry in the same enclosure with singular success. He has nearly an acre enclosed with a close slab fence, about seven feet high. The top of the fence is every where sharp pointed like pickets, though, perhaps, this may not be necessary. Within this enclosure are put up slight small sheds, well secured from rain, however, for the different kinds of poultry, and it is supplied with a small stream of water. The poultry are regularly fed three times a day with boiled potatoes, which is their only food, except what grass may grow within the enclosure.

The dung of the poultry, which is exceedingly rich, is carefully saved for use; and the turf of the enclosure is occasionally pared off for mixing with composts.

We have heard it asserted that a little molasses, or any other saccharine substance is very useful to mix with the food of poultry, which it is intended to fatten. Perhaps it might be well to boil a proportion of beets, ripe and sweet pumpkins, or squashes with potatoes, for the food of poultry. When corn is given to fowls it should be crushed or soaked in water. Hens it is said should have access, in winter, to slack-lime, or oyster shells, otherwise they will afford no eggs, as something of the kind is necessary to form the shells. Wheat, however, if given to fowls for food, will afford the substance (phosphate of lime) which is necessary to compose their shells.

BEEES.

Dr. J. Anderson in one of his papers on husbandry observes, in substance, that bees are frequently induced by mild weather in the winter, and early in the spring to leave their hives and by sudden changes to cold or wet become chilled, unable to return, and perish. And when they do not venture abroad, warm weather, out of season, often rouses them from their torpid state and obliges them to consume their stores, and they are then starved with hunger.

To prevent such accidents, Dr. Anderson is of opinion, that "no method would be so effectual as that of placing the hives in an ice house at the approach of winter. Here they may be kept till the spring is so far advanced, that no danger is to be apprehended from bad weather. During the whole winter they will remain in a state of torpor and require no food. As soon as the mild weather invites them to appear, they will commence their labors with vigor. The intense degree of cold which bees sustain without the least injury in Poland and Russia, where even quicksilver is sometimes frozen, removes every doubt or anxiety, concerning the safety of bees in an ice house."

We do not know that any thing has ever been attempted to ascertain the correctness of Dr. Anderson's theory, but wish that some person would try the experiment, and give the result to the public.

STUBBLE.—BURNING OF.

Mr. W. CURTIS, of Lynn, Norfolk, found very beneficial effects from burning the stubble of oats, which was left eighteen inches high for this purpose, on a field broken up from old pasture the same year; he afterwards sowed wheat and oats in succession on the same ground, the stubble of both of which was burned in the same manner. The ashes were in every case ploughed in to a small depth, and the verges of the field mowed previous to the burning, to prevent accidents. After the third crop of corn, all of which were abundant and remarkably free from weeds, the field was laid down with clover and grass seeds, and the ensuing crops of both hay and grass proved infinitely finer than those before the ground was broken up.

Another piece of land was cropped for three successive years in the same manner as the first, to which it was similar in every respect of soil, aspect, and previous management, but in which the stubble was ploughed in, instead of being burned; the produce of each crop on it was much inferior to that of the first experiment, and the weeds increased so greatly, that on laying it down to grass, they overpowered the grass seeds so much that it was necessary to re-sow it; and ever after, while Mr. Curtis held it, the grass and hay produced were coarse and full of weeds, and consequently inferior both in value and quantity to those of the other field, on which the stubble had been burned.

In burning stubble, the danger which is to be apprehended from the spreading of the flames, may perhaps be obviated by tracing a furrow round the field, and setting fire to the stubble on the inner edge of the furrow.

We were furnished with the following receipt by a lady, a pattern of industry and all domestic virtues, at whose table we have drunk this wine in great perfection. It is desirable that wine, and beer, and cider should take the place, as far as possible, of ardent spirits, the extravagant use of which has already become the scourge of this young country. It is, therefore, to be wished, that every thing which can increase the means or throw light on the manner of making these simple and wholesome beverages, should be made known for public benefit; and we shall feel much obliged for all information on such matters. The receipt is copied from "Cary's American Museum," for July. *American Farmer.*

RECEIPT FOR MAKING CURRANT WINE.

Gather your currants when full ripe; break them well in a tub or vat, (some have a mill constructed for the purpose, consisting of a hopper, fixed upon two lignum-vita rollers) press and measure your juice, add two thirds water, and to each gallon of that mixture, (i. e. juice and water) put three pounds of muscovado sugar, (the cleaner and drier the better; very coarse sugar first clarified, will do equally as well,) stir it well till the sugar is quite dissolved, and then turn it up. If you can possibly prevent it, let not your juice stand over night, as it should not ferment before mixture

Observe that your casks be sweet and clean, such as never had either beer or cider in them, and if new let them be first well seasoned.

Do not fill your casks too full, otherwise they will work out at the bung, which is by no means good for the wine; rather make a proportionable quantity over and above, that after drawing off the wine you may have a sufficiency to fill up the casks. Lay the bung lightly on the hole to prevent the flies &c. from creeping in. In three weeks or a month after making, the bung-hole may be stopped up, leaving only the vent-hole open till it has fully done working, which generally is about the latter end of October. It may then be racked off into other clean casks if you please; but experience seems to favor the letting the wine stand on the lees till spring, as it thereby attains a stronger body, and is by that means in a great measure divested of that sweet luscious taste, peculiar to new made wine; nay, if it is not wanted for present consumption, it may without any damage stand two years on the lees.

When you draw off the wine, bore a hole, an inch at least above the tap-hole, a little to the side of it, that it may run clear off the lees.—The lees may either be distilled, which will yield a fine spirit, or filtered through an Hippocrates' sleeve and returned again into the cask. Some put in the spirit, but I think it not advisable.

Do not suffer yourself to be prevailed on to add more than one third juice as above prescribed, in hopes that the wine may be richer, for that would render it infallibly hard and unpleasant, nor yet a greater proportion of sugar, as it would certainly deprive it of its pure vinous taste.

By this management you may have wine, letting it have a proper age, equal to Madeira, at least superior to most wines, commonly imported, and for much less money.

In regard to the quantity of wine intended to be made, take this example, remembering that twelve pounds of sugar are equal to a gallon of liquid.

For instance, suppose you intend to make 30 gallons, then there must be,

2 gallons of juice.	24 gallons of mixture,
16 of water,	3 multiplied by,
24 gallons of mixture,	12)72
6 gals. from sugar.	equal to 6 gallons of
30 gallons.	liquid.

and so proportionably for any quantity you please to make.

The common cider presses, if thoroughly clean will do well in making large quantities: the small hand-screw press is most convenient for such as make less.

N. B. An extraordinary good spirit for medicinal and other uses, may be distilled from currant juice by adding a quart of molasses to a gallon of juice, to give a proper fermentation.

American Kinglass.—A manufactory of this useful article has been established at Cape Ann, by Mr. Wm. Hall, late of this city. The material for manufacture is obtained from fish taken from our coasts. The specimens of isinglass manufactured at Cape Ann have been used by the brewers and confectioners in our city, who considered it fully equal if not superior to the imported.—*Boston Patriot.*

NEW ENGLAND FARMER.

BOSTON.—SATURDAY, AUGUST 3, 1822.

TO THE PUBLIC.

It was well observed by an eminent philosopher that "the excellency of manufactures, and the facility of labor would be much promoted if the various expedients and contrivances, which lie concealed in private hands, were, by reciprocal communications, made generally known. There are few operations that are not performed by one or other with some peculiar advantages, which, though singly of little importance, would by conjunction and concurrence, open new inlets to knowledge, and give new powers to diligence." The remarks will apply with as much force to Agriculture as to manufactures. One great and primary object of the "*New England Farmer*," is to serve as a vehicle for "reciprocal communications" of such improvement in husbandry, or domestic economy, as may add stimulus to industry, by insuring to diligence that reward which alone waits on well directed effort. The Proprietor would, therefore, be happy to receive useful hints, statements and essays, oral, written or printed, relative to the objects of his paper, as mentioned above, and more particularly unfolded in the first article of the preceding pages, from persons whose experience, reasoning or observation qualify them to furnish useful information to the community.

It is hoped that no practical farmer will be deterred from forwarding to us for publication any information of the above description from an apprehension lest style should prove deficient in any of the requisites what is called fine writing. All we wish for is that should make his meaning understood, which may be done as well, or better, by plain words and common phrases, than by a pompous diction, consisting of words of "learned length and thundering sound." If a literal correction should be deemed necessary to fit a matter for the press, which we may receive from correspondents, it will be cheerfully rendered by the Editor.

The Proprietor will spare neither pains nor expense to make his paper worthy of public patronage. He proposes, from time to time, to give engravings of improved breeds of animals, agricultural implements, patented machines for facilitating processes in the useful arts, particularly those connected with Agriculture and Domestic Economy.

At the termination of each year from the commencement of the paper, will be given a copious and correct index of the volume preceding.

The Proprietor authorizes and requests all Post Masters to receive subscriptions for the *New England Farmer*, according to the terms stated in the first page of this day's paper, and retain ten per cent. on the amount which they may collect.

We have taken the liberty to forward the first number of the *New England Farmer* to some gentlemen whose names happened to occur to us, although they are not on our subscription list. Should they approve of this specimen of our work, and the plan as developed in this and the initial articles, we hope they will afford us their patronage, and assist in extending the circulation of the paper by such means as they may deem adapted to that effect.

It was stated in our Prospectus that the *New England Farmer* would be printed on a "large royal sheet." It has since been thought best to issue it on a sheet of smaller size, but of superior quality. The price of the paper now used is the same as that at which we originally proposed printing it. We are confident our patrons will be satisfied with the alteration.

FOREIGN SUMMARY.

Intelligence from London as late as the 13th of June, has been received by the ship *Nestor*, arrived in New York from Liverpool. A London article of that date states that advices had been received from Constantinople to the 11th May, confirming the pacific news of the evacuation of Moldavia and Wallachia by the Turkish troops. Russian vessels were clearing at Odessa for Constantinople; and several vessels have been insured at Lloyd's from capture or seizure by the Turks, at one per cent.

It appears that the unfortunate Greeks are still suffering all that the most savage ferocity can inflict under the domination of the Musselmans. Two French gentlemen, visiting the island of Scio, represented the town as pillaged and destroyed, and the streets filled with the festering remains of the butchered inhabitants. The women and children were articles of commerce, both at Constantinople and Smyrna. The Turkish fleet was to sail from Scio about the 5th of May, which gives little hopes of their having been defeated by the Greeks.

The Belgrade accounts are very unfavorable to the Greeks. The Pacha of Salonichi had received reinforcements, and defeated the Greeks. After this he fell upon thirty Greek villages, and carried away the women and children as slaves.

The King of France, in reply to the Address of the Chamber of Peers says, "since the opening of the session I have received accounts which assure that peace will not be disturbed in the East."

It is stated that the accounts received from the South and West of Ireland continue more and more deplorable. The assistance given to the poor has been extremely liberal; but their wants exceed the donations. Dublin paper states that "a million of men, women and children are starving—are actually dying of hunger, and in one of the finest seasons ever remembered; malignant fever, with every appearance of the worst symptoms of pestilence has set in."

The recognition of the Independence of the South American nations, by the United States, has been received in Spain; but no measures have been taken on a subject.

The bill for throwing open the West India Islands to the trade of all nations had passed the House of Commons, been read a first time in the House of Lords, and is said will become a law.

As an illustration of the singular character of the winter, it may be mentioned, that while the thermometer was some degrees above the freezing point in Russia and Sweden, they were skating and driving in ice at Madrid through the whole of January, and several persons were frozen to death in the streets of Lisbon.

The last accounts from Spain, which are to the 31st June, indicate a crazed and unsettled state of society.

Troops of partisans are in arms against the government. These insurgents who style themselves royalists, are commonly headed by priests or monks, and their banners were inscribed, "*The King and the Cross*." They have been often defeated, but rise from every overthrow with apparently renovated strength and fresh exertions. The Cortes were in session, but were said to be perplexed, bewildered and wavering in their councils. They had fixed the standing army in 1822, at 62,043 men.

The Cortes have issued a Manifesto on South American affairs, in which they invoke the Powers of Europe to recognize the Independence of the New States of South America.

A duel was fought in Paris, in the beginning of June, between two members of the Chamber of Deputies, Benjamin Constant and Forbin Desjardins. They were attended by two seconds each. The former being lame, and unable to stand, they were both provided with chairs, and in that way exchanged two shots without effect; when the seconds interposed.

At a splendid levee held by the King of England, on the 12th of June, Mr. Washington Irving was presented by the American Ambassador.

DOMESTIC SUMMARY.

Slaves.—The Emperor of Russia has decided the question submitted to him by the U. States and G. Britain, in relation to slaves carried away during the late war by the British—that the U. States are entitled to a just indemnification for all such slaves carried away.

Riot at the State Prison.

On the first inst. there was a formidable insurrection at the State Prison in Charlestown. It commenced by an attack made on one Chadwick, who had rendered himself obnoxious to the prisoners by giving evidence against Green, not long since convicted and executed. It is said that for nearly two hours the rioters had the ascendancy, and were not quelled till after they had set fire to the workshops in the yard, and had been repeatedly fired upon by the guard. A large number of the citizens of Boston and Charlestown were collected, including Fire Companies, and a party of Marines from the Navy Yard. The principal of the riot, and several others were wounded, the former, it is supposed mortally. The culprits were at length driven to their wards and secured.

Negro Plot.—A plot has been formed by the negroes of Charlestown, S. C. to massacre the white people. They formed themselves into a society, and held meetings at a farm, which they could approach by water to avoid being stopped by any patrols. They intended to have provided themselves with passes so as to deceive the guard, and place themselves at certain parts of the city; then a party was to secure the guard at the guard house, and an indiscriminate massacre was to commence on all whites, who appeared in the streets, and particularly to prevent any company from forming. Also to prevent the bells from ringing to give any alarm. A negro who was solicited to join the gang declined, and gave information to his owners by which means the conspirators were arrested, and some of them condemned to be executed.

Solomon Southwick, Esq., the Editor of the Plough Boy, has been nominated a candidate for Governor of the State of New York, in opposition to JUDGE YATES. This event took place, says the Albany Argus, at "a very numerous meeting of Republicans," in which the "Capitol was crowded to excess, and the citizens animated by the fire of seventy-six and ninety-eight."

It is reported that another challenge has passed between Col. Cumming and Mr. McDuffie, and that the meeting is fixed for the 10th of August.

A writer in the Boston Centinel of the 31st ult. in remarking on certain recent failures, which have taken place in this city, says that "many of the failures were trifling, many others not unexpected, and that the whole will not effect the stamina of the solvent Emporium of New England commerce."

We have published the official decisions of the American and British Commissioners made under the 6th article of the treaty of Ghent; by which it will be seen, that all the islands in the Niagara river, (except Navy Island) have fallen to the United States. Drummond's Island, in Lake Huron, containing a British post, has also fallen to us. This will serve as an exchange for the military works at Rouse's Point, on Lake Champlain.—*Buffalo Patriot* July 10.

Counterfeit.—Counterfeit bills of five dollars, of the Bank of the United States, are in circulation, and have appeared in this vicinity. The engraving is coarse, and the paper much thicker than the true bills.

Salem paper.

We are informed by a respectable physician that a dog, evidently affected with Hydrophobia, was killed at Lechmere Point on Monday last.—*Palladium.*

Worcester Canal.—It is announced in the Providence American, that Mr. Benjamin Wright is engaged to survey, early the ensuing autumn, the route of the proposed Canal from Worcester to Providence, and to make an estimate of the expense of the undertaking.

Edmund Law, Esq. is a candidate for Congress in Florida. He was, we believe, brother to the late Lord Ellenborough, and author of many of the essays on the currency, which appeared in the National Intelligencer a short time since—a gentleman of genius, learning, and extensive and profound erudition.

American History.—The Evening Post intimates, that the Hon. Timothy Pickering of Massachusetts, contemplates writing Memoirs of his own Times, or some similar work. The following is the paragraph conveying the intimation to which we allude:—

"We express a hope, and we have good grounds for the expression, that this venerable statesman will devote the evening of his days to placing on record, the history of those events and transactions so familiar to

his remembrance, so honorable to himself, so glorious to his country. To what better purpose can he devote his time? How can he serve posterity more essentially, than by placing before their eyes, in an impartial light, the picture of the times that have been? He has served his country in the field and in the cabinet; let him close his labors by acting as the historian of his own times."

Mr. Pickering has now reached the age of seventy; and as he is one of the living chronicles of revolutionary events, such a work as he contemplates would no doubt contain many valuable facts which would serve to illustrate our history.—*N. Y. Statesman.*

Charles Thompson.—A gentleman of this city lately visited the venerable Charles Thompson, secretary of the continental congress in the revolutionary war, at his seat, twelve miles from Philadelphia, on the old Lancaster road. Mr. Thompson has reached the advanced age of ninety-three, enjoys tolerable bodily health, and walks with apparent ease and pleasure; himself; his sight is so good as to enable him to read without spectacles, but he hears with difficulty—his mind is evidently in decay; it is the ruins, however, of superior intellect; far from being juvenile, it still bears the impress of greatness, and a familiarity with the best ancient and modern authors. He dwells with peculiar interest on the scenes of the revolutionary war, and relates with great precision, many anecdotes of its prominent characters. On being asked what caused such implicit faith to be put in the documents signed by him, he answered "it was well known that he had resolved, in despite of consequences, never to put his official signature to any account, for the accuracy of which he could not vouch as a man of honor;" and so well was this understood, that when Mr. T. was adopted by the Six Nations of Indians, they emphatically named him "the man of truth."—*Albany paper.*

DEATHS.

In this city, Mr. Thomas Pelham, 38.—Mr. John Burt, 29.—Miss Ann Hughes, 67.—Mr. John Holbrook, 53.—Augustus O. Barton, 39.

In Roxbury, on Thursday last, James Perkins, Esq. of this city, aged 61.

In England, Stephen George Kemble, Esq. the celebrated comedian, aged 64. In private life he was a social, lively companion; and on the stage he was remarkable for playing Sir John Falstaff, without stuffing his jacket.

New Printing Office.

THOMAS W. SHEPARD

RESPECTFULLY informs his friends and the public that he executes all kinds of

Book and Job Printing,

in the most fashionable manner, and on reasonable terms, at the Office of the NEW ENGLAND FARMER,

Rogers' Building.....Congress Street.

Entrance Nos. 4 and 11.

Husbandman and Housewife.

FOR sale at the Bookstore of Charles Ewer, No. 51, Munroe & Francis, No. 4, Cornhill, and at this Office:—THE HUSBANDMAN AND HOUSEWIFE; being a collection of valuable Recipes and Directions, relating to Agriculture and Domestic Economy. By THOMAS G. FESSENDEN, Esq. Price 50 cents.

The following notice of this work is extracted from the *Massachusetts Agricultural Journal* for June 1822.

"We have read it with attention, and think it well adapted to the use of farmers, who would not go to the expense of purchasing larger works. It is a collection of receipts, many of which are from high authority, and all of them, as far as they are accurate, calculated for daily and constant use. That errors should creep into such a work must be expected. The recipes are often taken from such transient works, or sources, that it would be impossible for the compiler to vouch for their efficacy or exactitude—but still its use must be very great to the class of people for whom it was principally intended."

August 3

From the Massachusetts Spy of July 24.

Mr. Editor—The following communication from an intelligent practical Agriculturalist, embraces a subject of reasonable and important interest to the farmers.—The question of the effect produced upon the crop of Indian Corn by removing the *Suckers*, and the proper manner and time for doing it, are yet to be decided by more frequent and accurate experiments than appear to have been made, the results having been very different, in the instances heretofore communicated. As the season has now nearly arrived, in which the experiment may be repeated, it is hoped that every Farmer will give so much of his time and attention to the subject, as to take the suckers from at least a single row of his corn, and carefully note the time and manner of doing it, with the comparative product of a similar quantity on which the suckers shall be permitted to remain—and if he will still further ascertain the difference between cutting the stalks and leaving them to be harvested with the Corn, and communicate the result of all his observations to this Society, he would add much to the stock of useful information, and greatly oblige his fellow-laborers in the business of Husbandry.

L. LINCOLN, Cor. Secretary of the Worcester Agricultural Society.

To the Worcester Agricultural Society.

In the spring of eighteen hundred and twenty-one, I proposed to try the experiment of raising Corn, by planting it in rows. I ploughed the ground, as usual, twice; then carted twenty-seven loads of barn manure on an acre, which took two men with a yoke of oxen one day.—As soon as the manure was warmed by the influence of the sun, I then spread the same, and ploughed the ground for the third time. On the eighteenth of May, I furrowed it out, three feet six inches from centre to centre of the furrow—then carried on twenty-five loads of loam, which was carted into my hog-yard the preceding Autumn, and spread the same in the furrows, which took three men and a yoke of oxen one day—I then planted one half the ground in two rows, six inches apart, the remainder about nine. Immediately after weeding it, I spread two bushels of plaster on the rows—at a suitable growth gave it a second hoeing; the second week in July, hoed it the third time; at that period the growth was very rapid, and there appeared to be a greater quantity of suckers from the bottom of the stalks than I ever saw before. The observation struck me, that it would be worthy the attention of our Agriculturalists to try the experiment of cutting the sucker from the stalk, which I did from most of it. By observing, I found that such a proportion of juice from the stalk went out where the sucker was taken off, that the growth was not so large, and the ear set higher upon the stalk: on the part where the suckers were not taken off, the corn was thicker set and more prominent—the ears set ten or twelve inches higher the ground, and were a good proportion larger. That part of the field that was planted thinnest, was the largest growth; the stalks and ears thicker set, and the corn set higher the ground. The quantity of corn that grew on an acre was eighty-one bushels.—From the best observations that I have made, I would recommend to any gentleman, wishing to try the experiment of planting in rows, to furrow the ground four feet apart from centre to centre—to plant the corn in two rows, nine inches apart, diamond fashion. It is a very simple process, to level the manure when spread in the furrows, and take a pair of small wheels, with cogs in them, made for that purpose, put them on an axle-tree nine inches

apart, which will dot the ground with accuracy, when drawn across the field, so that a child of ten years may drop the corn without the least difficulty.

LEMUEL DAVIS.

Holden, March 13, 1822.

We are inclined to believe that Mr. Davis would have had a larger crop of corn if it had not been planted so thickly. "Three feet six inches from centre to centre of the furrow" with two rows "six inches" or even "nine inches" apart, if the corn was of the common size of our New England corn might, perhaps, ever stock the ground with plants.

We are told that Mr. Stevens, of Harkimer County in New York, raised one hundred and eighteen bushels of Indian corn to an acre. He planted his seed in double rows about eight inches apart, and the seeds were set diagonally (or diamond fashion as Mr. Davis expresses it) the same distance from each other in the rows. Between each of the double rows was left a space of five and an half feet.

Mr. Ludlow, of the same county, raised ninety-eight bushels to the acre. He planted his seed in single rows, four feet apart, with the grains set eight inches asunder. His land was not so highly manured as that of Mr. Stevens.

Mr. Hummwell, of Massachusetts, raised one hundred and eleven bushels of corn from an acre of ground, which was furrowed out at a distance of four feet (if we recollect rightly, as we have not the statement now before us) leaving each furrow a foot wide the seed planted in the drill on each furrow, making three rows to each furrow, and care taken to drop the corn as near six inches apart as possible without wasting time.

With regard to taking suckers from corn we would recommend, in addition to the experiments suggested by the Hon. Mr. Lincoln, that trial be made of bending them to the ground, and covering them with earth sufficient to kill them, which has frequently been stated as the best mode of disposing of them; as they thus, it is said, serve as manure to the principal stocks.

Long Woolled and Broad Tailed Sheep of Africa.

The Hon. Dudley L. Pickman, of Salem, has presented to the Massachusetts Agricultural Society a Ram of this breed, first imported.

A Ram and Ewe, of the first race introduced into this country, were presented by Gen. Eaton to the Hon. Timothy Pickering, then resident in Pennsylvania, by the name of the Barbary Mountain Sheep. The President of the Philadelphia Agricultural Society some years afterwards, gave the following high character of the breed, in the memoirs of that Society:

"I know not any breed of sheep superior and few equal to it. Its fleece is of the first quality; and the valuable parts singularly good. No other African Sheep is to be compared to this species, either for fleece, fattening, or hardiness. It bears our severest winters without shelter. Some of the best lamb and mutton sold in our market are of this breed; which is now spread through many parts of this State and Jersey."—(Memoirs vol. I. page 163.)

General notice is hereby given to the Farmers of Massachusetts, that the Ram now at E. Hersey Derby's, and at the disposal of the Trustees of the Society, will be delivered to any gentleman who is desirous to obtain a cross from this breed, free of cost, and upon the sole condition of good treatment of the animal, and to be kept within the State. Application to be made immediately to either of the subscribers.

E. HERSEY DERBY, Salem.
JOHN PRINCE, Roxbury

From the Mass. Agricultural Repository for June.

Dr. Deane's New England Farmer.

In our last number we mentioned that Messrs. WELLS & LILLY had caused this valuable, and as we think, standard work to be revised at their own expense, and had put it to press. A wis- to render it as perfect as they could, to incorporate in it most of the improvements which have taken place in agriculture since the publication of the second edition, and to expunge from it all superfluous matter, or opinions which are now exploded, has delayed the work to this time.

It will probably appear in the course of a few weeks. We have no other interest in introducing this subject again to the notice of our readers and subscribers, than the wish to diffuse correct agricultural knowledge. Dr. Deane's work was certainly as good a compendium of its size, as could be found in Europe at the time it was published. It had the special merit, for us, of adapting European modes of culture to our soil and climate. Even in its improved state, it is not pretended that the work supersedes the necessity, with intelligent cultivators, of an extensive agricultural library, but it is calculated, and well calculated, to aid the experience, and enlighten and direct the practice of all descriptions of farmers. It has been necessary so far to enlarge it, in consequence of the great modern improvements in agriculture that it may prove too expensive for small farmers, but we think all farmers in easy circumstances will find it a very cheap book. Many things will not be new to them, but even the they will find enforced by new reasons and arguments. Though written principally with view to the New England States, there is a part of the United States in which it will not be found of great value, and perhaps it may not be and ought not to be its smallest recommendation to the farmers of the United States, that excepting the Rev. Jared Elliot's small tract, was the earliest and by far the most respectable agricultural work ever published in the United States. The Farmer's Assistant by Mr. Nicholson, of the State of New York, a very respectable work, is apparently modelled upon it, and I presume the author will admit, what indeed his pages prove, the great assistance derived from this work.

But in New England, it was thought best to republish Dr. Deane's work, with additions and corrections, not with the wish, in any degree, to interfere with the other work alluded to. Far from it, Messrs. Wells & Lilly, to our knowledge, contemplated and proposed to the writers of this notice, the republication of Dr. Deane's work, before the Farmer's Assistant went to the press.

We repeat, that as Editors of this journal and as individuals, we have no other interest, or wish to promote the circulation of a new edition of Dr. Deane's New England Farmer's Dictionary, than the advancement of sound principles in agriculture. We wish to see all agricultural publications of merit, and we have alluded to the Farmer's Assistant, not to add, that we think that work is one which deserves this character. We trust the demand of ten millions of people will be great enough for both, and in a few years, for many others.

From the Mass. Agricultural Repository for June.

AN ESSAY

On the Advantage of Manuring with Green Crops.

BY S. W. POMEROY, ESQ.

First Vice President of the Society for promoting Agriculture in Massachusetts.

That eminent chemist, Sir Humphrey Davy, who has shed so much light on the practice as well as on the philosophy of Agriculture, observes, that "land when not employed in preparing food for animals, should be applied to the purposes of the preparation of manure for plants; and that this is effected by means of green crops, in consequence of the absorption of carbonaceous matter in the carbonic acid of the atmosphere. That, in a (naked) summer fallow a period is always lost in which vegetables may be raised, either as food for animals or as nourishment for the next crop."

The rewards offered by the board of Trustees of the Massachusetts Agricultural Society for more than twenty years successively, for the best experiments on ploughing in green crops for manure, appear to be still unclaimed; there is of course good reason to believe that the practice is very limited in the Commonwealth. To shew the advantages that result from such a system, elsewhere, the following is transcribed from a letter that I addressed to John S. Skinner, Esq. of Baltimore, the able and zealous Editor of the American Farmer, and which appeared in that paper last November.

"Among the various plants applied as green dressings for the restoration of worn out soils, the WHITE LUPIN stands pre-eminent in those climates that will permit their growth between the periods of harvest and seed time. That a trial may be made with them, I have forwarded half a bushel of the seed, which I trust you will cheerfully distribute for the benefit of our Southern brethren. They were sent to me from Fayal; and the following account, which I have collected, of the effects of their culture, will, at least, serve to convince us, that "the Earth, ever subservient to the wants of man," when exhausted by his insatiable demands, requires from him but a little mechanical aid, to enable her still to 'spread his walks with flowers and his table with plenty.' The island of Fayal, though in the same parallel of latitude with Maryland, is subject to a temperature seldom above 80, or below 50 degrees of Fahrenheit. The soil is thin, and incumbent on scoria and other undecomposed volcanic substances; but naturally exceedingly fertile. For a long period of time, every part accessible to the plough, has been in tillage; and, with the exception of selected patches shifted for flax, under alternate crops of wheat and Indian corn, (the latter being the chief food of the laboring classes.) Such a system of severe cropping; the resources for manure very limited, and without the advantage of improved implements or modes of culture, caused a visible deterioration of the soil; the crops lessened from year to year; partial importations were resorted to; and the well born of the island became seriously

apprehensive of the most distressing consequences.

"Providentially, some 15 or 20 years since, the White Lupin was introduced from Italy, and though it came by accident, to a people strongly bigotted to old practices of husbandry, the cultivation soon became general.

"The wheat and corn are harvested in August, the land is soon after ploughed and Lupins sown on the surface, or but slightly covered, at the rate of two bushels per acre. In February they flower, and are then turned in with the wheat, corn or flax in their several rotations. By this management a progressive improvement of the soil has become apparent: there are no longer apprehensions of famine; a very redundant population subsists; and besides supplying 10,000 on the neighboring island of Pico, where scarce any thing but the vine is cultivated, a surplus is often sent to other islands, and in some instances to LISBON!

"Lupins are ranked by Gardeners among the hardy annuals, but I am not able to say what degree of frost they will bear. From a single experiment I am led to believe that, owing to the droughts to which our climate is subject, not much advantage will be derived by sowing them on summer fallows as a dressing for winter crops. Their application to spring crops, in those sections of our country where they can be grown in season for that purpose, will probably become the first object of experiment."

The culture of crops to plough in for manure, is by no means a modern practice. The Romans, eighteen hundred years ago, according to Pliny, cultivated and applied Lupins for manure in the same manner precisely as they now are in Italy, and in Fayal.* But this plant is supposed to be unsuitable for our climate:—we should not despair, however, of finding a substitute.

It has been asserted by Sir Humphrey Davy, that it is a general principle of chemistry, that in all cases of decomposition, substances combine much more readily at the moment of their disengagement, than after they have been regularly formed. And in fermentation beneath the soil the fluid matter produced, is applied instantly, even while it is warm, to the organs of the plant, and consequently is more likely to be efficient than in manure that has gone through the process. He also remarks, that it may be doubted whether there is as much useful manure at the end of a clean (green crop) fallow, as at the time the vegetables clothing the surface were first ploughed in. That the action of the sun upon the surface of the soil, tends to disengage the gaseous and volatile fluid matters that it contains; and heat increases the rapidity of fermentation; and that in the summer fallow (with green crops) nourishment is rapidly produced, at a time when no vegetables are present capable of absorbing it."

Such expositions show the importance of selecting plants that will arrive at sufficient stature and succulence, in season for spring crops; and it may be well to inquire what vegetables

there are within our reach, that can be successfully applied.

CLOVER is unquestionably one of the greatest improvers; but a season is lost by its application. There is another objection—*weeds and wild grasses* that rise with it, the first season, ripen and shed their seeds; the effects of which are severely felt in the succeeding tillage rotations.

BUCK WHEAT has been most used in this country for green dressings; and doubtless with good effects on summer fallows for winter crops; but, besides not coming on early enough for spring crops, it often leaves the land foul with its own seeds; and is allowed, on all hands, to be a great exhauster.

I am aware that an opinion generally prevails that if plants are cut in the milk, as it is termed, or ploughed in before they ripen their seeds, that the soil is not exhausted! I presume this theory is founded on the supposition, that while the stalk and foliage are green, the supplies are drawn from the atmosphere; but as soon as they become shrivelled, the seeds are perfected with food exclusively from the soil.

This reasoning is plausible, and possibly correct as to certain classes of vegetables, but the position should in all cases be admitted to a very limited extent.

The hum of bees in a field of buck wheat, and the flavor of the honey from the hives in the vicinity, afford strong presumptive proof that the atmosphere does not alone produce such sweet results!

There is another consideration that should govern us in the selection of plants for the object in view. It cannot be doubted, but that the soil contains, not only materials suited to particular vegetables, but that several species require the same principles to furnish their food. Now from an experiment, well defined, twenty years ago, with oats cut in the milk, and from constant observation of the effects of their culture on my neighbor's land since, I feel a thorough conviction that they exhaust the soil of those materials or principles necessary for clover and other grass, to a degree very destructive to those all important crops.

And such have been my impressions that their deteriorating effects on the soil would be lasting, that a few years since, I restricted a tenant in a lease which he now holds, from sowing oats, even to cut in the milk, under a penalty of an increased rent of ten dollars an acre,—I wish to be understood, that these observations are meant to apply solely to dry soils—such as are suitable for Indian corn or wheat—and in our dry climate.

MILLET is a plant, the cultivation of which is increasing, and as an important article for fodder, or for soiling, will probably within a short period be more fully appreciated, that seems well adapted to sow on summer fallows for winter crops, or to turn in late in the fall to enrich the land for the ensuing spring tillage or other spring crops. Of the exhausting properties of millet I am ignorant, but from the bulk of the stalk and foliage, it must make large draughts from the atmosphere, and copious re-

* See Pliny's Nat. Hist. Book 17, chap. 9, book 12, chap. 14—27.

turns to the soil. The cheapness of the seed is much in favor of its extensive application.

Of all the vegetables that may be best substituted for the Lupin. Rye, in my opinion, is the most promising. This plant, too much neglected to produce food for brutes, but what is to be lamented, *too much cultivated to furnish poison for men*, possesses all the ameliorating properties for the soil, that we are accustomed to derive from any of those belonging to the *leguminous* tribe. Rye withstands severe drought; and without manure it feeds millions in some countries, from soils little better than blowing sands.

Those soils inclining to loam, that will produce a rank *stubble*, are said to be enriched by a succession of ripened crops; and it is a fact within my own observation, that rich *friable* loams, on the alluvial banks of Connecticut, which have been exhausted by repeated, *unmanured*, crops of *Indian corn*, have been in some measure restored by two or three successive crops of Rye. If it will do this with the *dry stubble*, what may we not expect from it *green*, when buried rampant and succulent in the soil?

In order to insure a sufficient growth, in season, to plough in with *Indian corn* and most of our root crops, Rye should be sown the beginning or by the middle of August, and much thicker than when intended for a crop of grain. If it gets too forward before winter, it should be fed down with *light stock* or mown. Winter Rye, sown early in the spring grows rapidly, and will generally arrive at sufficient stature in season to be turned in as manure for *Ruta Baga*. Rye ploughed in when in full flower and *Millet* sown, which it will bring forward with great luxuriance, and that in its most succulent state, turned in for *Wheat*, may be one of the best fallow preparations for it that can be devised; and is probably the cheapest and most convenient process to restore an exhausted soil. At the same time it should be considered, that *gypsum* acts more powerfully on soils thus prepared.

I have been induced to submit the foregoing remarks, not only from an impression that such a system, as has been imperfectly suggested, will tend to increase our products immediately, and insure a progressive improvement of the soil, but from a firm conviction, that it is one of the most efficient resources that the farmers of New England can command, to enable them to meet the crisis that awaits them; and for which, perhaps, they are not fully prepared.

By the noble efforts of the State of New York, those fertile regions in the west, many hundred miles from navigation, will soon be approximated for every useful purpose, and produce the same effect, as if they were within forty miles of the Hudson. And I apprehend that the question cannot be too soon propounded—How is the *Massachusetts farmer* to meet in the market, on equal terms, the mass of agricultural productions which will then inundate the shores of the Atlantic?

Is it by *Canals*, in an uneven, confined territory, on which the most profitable staple is grazing? We have no inland seas mingled with mighty rivers, to feed levels through rich alluvial tracts of an hundred miles in extent! No inexhaustible reservoirs of *brine*, within twelve feet of the surface, seven times stronger than the waters of the ocean; and from which the

whole Atlantic seaboard may be supplied with the heavy article of SALT, as cheap, and of a *pur-*
er quality, than can be obtained from any part of the world! Neither do our mountains afford those valuable and ponderous minerals, the transportation of which on canals, contribute to the main support of those costly undertakings in Europe!*

On the other hand, would not greater benefits flow, were every dollar of capital that can be spared from commerce and manufactures, appropriated to those vast improvements of which the soil of Massachusetts is susceptible? And should a mania for water works arise, it may have ample and profitable gratification, by cutting *trenches* on the ridges and *tunnels* through the hills, thereby draining the numerous ponds, swamps and bogs, creating luxuriant meadows; and by erecting *hydraulic machines* on the innumerable streams and brooks to irrigate the parched fields on their borders! It is by such enterprizes that the Massachusetts farmers may expect to prosper, aided by a regular system of management, with the application of all the *manures* that can possibly be collected, on one third part of the soil that usually receives them, and by enriching the remainder by that joint process of nature and art, PLOUGHING IN OF GREEN CROPS.

MASSACHUSETTS AGRICULTURAL REPOSITORY AND JOURNAL, FOR JUNE.

(Continued from p. 2.)

Perhaps there is nothing which more serves to prejudice a great proportion of farmers against what they call *book farming* than injudicious attempts to carry into effect any improvement in husbandry without sufficiently regarding soil, climate, proximity to market, scarcity or plenty of land, low or high price of labor, and other circumstances, which may render a proposed system very eligible and proper in some cases, and very expensive and ruinous in others. *Science* may give us facts and theories—but *good sense* must make the application; and the more *knowledge* a man has, if he has not *judgment* to make a proper use of his information, the wilder and more ruinous will be his projects and calculations. But in such cases authors are no more culpable for having given misapplied directions, than the sun is to be found fault with for giving that light which enables a man to travel in a road leading him astray from his object. *Book farmers*, as they are called, are, however, sometimes *wrong*, therefore we should be cautious; but they are sometimes *right*, therefore we should not be too incredulous. If their doctrine is doubted, bring it to the infallible standard of repeated actual experiment; but if it carries conviction with it,—is assented to as soon as named, let us convert it to useful purposes. But we cannot better enforce and elucidate our meaning than by further quotations from the first article in the Journal which is the subject of our present notices.

"Some persons have doubted the applicability of the system of soiling to our country. By soiling, we mean, (as some of our readers may

* The canal from Lake Erie to the Hudson, 363 miles, will probably be finished in 1823. For 240 miles on its line not a single yard of rock is necessary to be removed! The average cost of the whole canal is estimated at \$13,500 per mile. The expenditure for canals in England average \$22,000 per mile. The Middlesex Canal is said to have cost \$17,000. Mr. Gallatin supposed the medium cost of canals in America would amount to \$21,000 per mile. See North American Review for January, 1822, Art. xii.

Brighton, 3d June, 1822

not be acquainted with the term, which we must confess is a barbarous one, having no sort of connexion with its real meaning) the feeding cattle either in the barn or barn-yard thro' the summer months with fresh cut green food. Mr. Quincy has very fully and very satisfactorily proved that it can be profitably done in our country—that its cost, compared to its usefulness is very small.

"We agree, however, with many farmers, that it is not *generally* applicable to our present state of agriculture. It is of great use where fencing stuff is dear—where grass is of great value—where cultivation is carried to great perfection—where population treads very close on the heels of production. But in our country, even in the populous parts of New England, (we say it with great respect for the gentleman who has called our attention to it,) we doubt whether it can be adopted with great advantage, except on lands in the vicinity of great cities, or on farms reduced to a state of great improvement and high cultivation, or on very small farms, where it is invaluable. For example, to myself, its value is beyond calculation. But my next neighbor, has a rocky pasture, to subdue which, to any tolerable state, for any sort of cultivation, would cost the whole value of his farm—but it makes excellent pasture land. The cattle thrive admirably among the rocks and shrubs of this stubborn pasture, which will never be cultivated, till our country shall count as China does its 270 millions of souls.

"Immense woods and pasture grounds exist within 50 miles of Boston, which can be used in no way so profitably as they are now used, for pasture. Till they are taken up and cultivated soiling will be limited, *must* be limited only to small cultivators, or great experimental farmers. If it be asked why *are not* these waste pasture lands taken up for cultivation? my answer is they are not wanted—they will not pay the price of reducing them to cultivation. They will remain as they are, till New England shall have its half a dozen Manchesters and Birmingham, and then soiling will become, and never till then, extensively in use."

Mr. Lowell concludes this valuable paper by stating his opinions relative to such objects as require the attention of those who would ameliorate the present system of Agriculture.

"My own ideas as to the most practicable improvements in the agriculture of this part of our country, are principally confined to the following particulars.

"First. The improvement of the character and qualities of all our domestic animals. It would not be extravagant to say that the expense and profits of raising stock would be beneficially affected by having the best races of every sort that are now known in Europe. New England will never be a grain country, any more than she will become the raiser of tobacco or cotton. But she can probably supply two millions of people with beef, pork and wool.

"Secondly. To do this, she may and must use for half a century her natural pastures, because she cannot afford at present prices, to break up her uncultivated lands, but she can raise, and raise to advantage, by a succession of crops, a sufficient supply of succulent roots, such as the Swedish turnip—the Mangel Wurtzel or white beet, carrots and potatoes, to come in aid of her cultivated and natural grass-lands, to support, and improve the condition of her stock of ani-

mals, to the extent of double, nay, I believe, treble their present numbers.

"They will not, they *cannot* exceed the demand, that must regulate the supply, after all we can say or write, but much may be done to enable us to raise cheaper and better animals. If *cheaper* the demand will be greater. We have done much in this way, but much remains to do.

"Thirdly, we are very deficient in Horticulture. To be sure there is no great profit in cash arising to the farmer from gardening beyond the limits of twenty miles from a great town—but when men have arrived to the degree of comfort which our farmers generally enjoy, they ought to seek innocent luxuries. We cannot hope or expect to see their front yards ornamented like those of the Dutch and English cottages, who are not worth a twentieth part as much as they are, with flowering shrubs and plants, so neat and so beautiful as to realize the description of the poets, who have descanted on pastoral life. This depends in those countries on fashion, and as the more opulent indulge in those luxuries, the others follow as imitators; but a delightful pear—an excellent plum or peach, or an admirable winter apple, fresh in April, would be as sweet to the palate of a farmer as to that of a luxurious and opulent merchant, and why these are neglected, I never could comprehend, as the labour amounts to a trifle in procuring and in preserving them.

"Perhaps New England owes its inferiority in these particulars more to the want of good nurseries, than to any other cause. No farmer ought to be without his asparagus bed, which, once laid down, will last without his labour for forty years—no one ought to be without his patch of green peas—lettuce—early and late beans. If more attention were paid to these comforts, we should hear less of spotted and typhus fevers in our otherwise healthy villages, and our females in the country would be more proud of the grounds about their houses, and take more interest in their neatness and comfort than some, perhaps too many of them now do. We do not mean to say, there are not a great many farmers who pay some attention to these things, but the deficiency is deplorable."

The next paper in the Repository is a letter from the Hon. TIMOTHY PICKERING, President of the Agricultural Society for the County of Essex, to John Lowell, Esq. Corresponding Secretary of the Massachusetts Agricultural Society. In this letter the honorable writer observes, in substance, that the greatest difficulty to be encountered in raising peas is to produce them free from bugs. An effectual remedy for this evil is *late sowing*; but the hot sun of June will so pinch the vines of the late sown peas, that the crop will be small; unless the land be *moist* as well as *rich*. He then details some experiments by which he concludes that this insect is limited to a certain period for depositing its eggs; and that if the tender pods are not found till that period has passed, the peas will be free from bugs. Mr. Pickering quotes the following from a paper, written by the late Mr. Bartram, a distinguished Naturalist of Pennsylvania.

"They (the pea bugs) feed, when in the caterpillar or grub state, on the green garden or field pea, as soon as the pods have arrived to a state of maturity sufficient to shew the peas which are within them. In the evening or on a cloudy day, the female deposits her eggs on the outside of the pods; these eggs or nits soon hatch, and the young larva or worm eats directly through,

and enters the tender young pea, where it lodges, and remains feeding on its contents, until it changes to a chrysalis, and thence to a fly or beetle, before the succeeding spring; but do not eat their way out until the colds and frosts are past, which is about the beginning of April, when we generally begin to plant peas." "After they have disseminated their eggs, they perish." "But that which is surprising and difficult to be accounted for, is, that the worm leaves the *rostellum* or sprout untouched, or at least uninjured; for almost every pea vegetates and thrives vigorously, notwithstanding the *corculum* (the rudiment of the young plant) and *plumula* seem to be consumed."

"One or two years observation," continues Mr. Pickering, "in different climates, may be requisite to ascertain the time when the flight of these insects is over and they perish. As peas of various sorts blossom and form their pods at very different times, some that come late may perhaps admit of such early sowing as to secure a vigorous and ample growth of the vines before the intense heat of summer arrives; in which case a satisfactory crop may more surely be expected."

Mr. Pickering concludes this paper with the following remarks on the opinions which some people entertain of the influence of the moon on agriculture and other sublimary concerns.

"Having noticed the folly of regarding the Moon in relation to the time of sowing pease, I add, that the idea of its influence in any other operations in husbandry, ought to be alike discarded. It is a mischievous supposition kept alive by tradition, and countenanced and supported by the idle remarks and representations in almanacks. The figure of a man marked with the signs, and the prognostications of the weather, ought to be expunged; and every well disposed almanack-maker would banish them if he knew the injuries they occasion, by misleading the farmer in any branch of rural economy. I once heard some farmers—speaking of spreading manure on grass-land in the spring—say very gravely, *that it should not be done when the horns of the moon were turned upwards, for then the manure, instead of sinking into the ground, would rise with the grass, and do no good*. On the contrary, they mentioned one farmer who would not set up his *worm fence* when the horns of the moon pointed downwards—for then the stones placed under the angles of the fence would sink, and the lower rails touch the ground and rot. And an industrious farmer in another state told me that he had slaughtered a fine heifer calf which he wished to have raised, *because it was dropped in the dark of the moon*. If I had not witnessed these facts, I should have hardly thought it possible that such ridiculous notions could have been entertained by any persons who claimed a share of common sense. Even the changes of the weather so generally supposed to be influenced by the phases of the moon, have been found, by long course of observations, to happen at all periods of the moon's appearance indiscriminately. This fact which your father mentioned to me twenty years ago, was this day repeated to me by the gentleman who had noted those observations. Were it otherwise, he remarked,—did the moon's influence determine the weather—then should not this be fair or foul, at the same times, in all countries on the globe?" (To be continued.)

Prayer of a Young Gentleman for a Wife.

From a vain coquette—from a pert assuming Miss, good Lord deliver me. From one whose time and thoughts are employed in dress, ornaments and visits; from one who is enamoured of her own pretty face and accomplishments, and "delighteth with her praise;" from one who talketh loud, affecteth much, and laugheth always, may I by a providence, be delivered.—From one who is not delighted with her home, whose eyes roll with boldness on the faces of men; from one who is insolent, proud and conceited, I earnestly desire to be delivered. From one who appeareth to be delicate beyond what is natural; from one on the contrary, who delights to be seen performing the duties of men; from one who is pleased with a gorgeous apparel; from one on the contrary who is sluttish, neglects her dress, and wanders about barefooted and barelegged, I pray to be delivered. From her who would be thought learned in the sciences, whose ambition is gratified in disputing upon politics and divinity; from one on the contrary who is ignorant, and delighteth not in books, I wish to be delivered. From one who is perpetually finding fault, fretful and uneasy; whose house and family will be kept in continual uproar by her termagant disposition, I ever pray to be delivered. From her whose treatment to her friends is all ceremonious; from her whose manners in company are awkward, who is too bashful to join in the conversation and amusements of polite company; who knows not when to speak and how to speak, may I be delivered. But grant me the hand and heart of that amiable, modest, unaffected, neat and virtuous fair, whose frankness and serenity manifest the disposition of her natural mind. Grant me one who walketh in maiden sweetness; with innocence in her mind and modesty in her cheeks. One who is adorned with neatness in her dress; whose conversation is instructive, pure and decent; one whose eyes sparkle love and kindness; one who delighteth not in slander and obscenity; one whose breast is the mansion of goodness, whose actions are the index of a pure and virtuous mind. Give me the girl who has not yet been taught to disguise the honest simplicity of nature, by the modes of behavior originating from the "beggary refinement of modern education;" one whose great beauty consists in mental accomplishments; and whose heart and conscience dare to avow the sentiments of her mind; one who shall alleviate my troubles by her counsels, and sweeten enjoyments by her endearments; whose answers are all mildness and truth; whose affections mitigate distress; and whose good humor and complacency banish afflictions. Such a young lady shall be the object of my affections. Such an one should be cherished as a blessing from above. The kindness of my behavior shall endear her to my heart. Happy shall I be to find such a wife. She shall be more precious to me than riches.

Dr. Franklin.—Lord Howe in a conversation with Dr. Franklin on Staten Island, in the time of the Revolutionary war, said "I feel a great affection for the people of America, and should be sorry for the fall of the people of this country." "We will endeavor to prevent your sorrow, my lord," replied Franklin.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.

SORREL.

"Over cropping and shallow ploughing, with exhausting crops in succession frequently cause overwhelming growths of sorrel to infest ill managed fields. Lime is the only remedy: and you will see in Lord Dundonald's "*Companion*" &c. the good effects of lime; which destroys the sorrel, and produces the sorreline acid, highly friendly to wholesome and profitable vegetation. Green sorrel grows on fertile soils; but the red sorrel is a certain mark of sterility."

Notices for a Young Farmer, &c. from Memoirs of the Philadelphia Agricultural Society.

All dung should be covered either with earth or a roof, to prevent evaporation and waste of its most valuable ingredients. Mix no hot lime with your muck, dung, or compost heap, before fermentation has ceased, or sufficiently advanced, as it injures moderate fermentation, and often consumes the muck. Instances of even conflagration of strawy muck by hot lime, to a great extent can be given.—*ibid.*

Cut or chaff your hay, straw, corn tops or blades, and even your stalks, with a powerful straw cutter and you will save a great proportion, which is otherwise wasted, or passed thro' the animal without contributing to its nourishment. One bushel of chaffed hay at a mess, given in a trough, three times in twenty-four hours, is sufficient for an horse, ox, or cow. A bushel of chaffed hay, lightly pressed, weighs from 5 to 5 1-2 pounds. An horse, or horned beast, thrives more on 15 lbs. thus given, than on 24 or 25 lbs. as commonly expended, (including waste) in the usual mode of feeding in racks; to which troughs properly constructed, are far preferable. Salt your clover and other succulent as well as coarse hay. But over salting diminishes the nutriment. More than a peck to a ton is superfluous. Half that quantity is often sufficient. Ten or fifteen pounds is usually an ample allowance. Feeding your stock by weight and measure of food will not only save your provender, by its orderly distribution, but frequently, the lives of animals, too often starved by niggardliness or neglect, or gorged and destroyed by profusion. If it be true, as it is that "the master's eye makes the horse fat;" it is equally so, that the master's eye prevents the horse from being pampered, wanton, pursive, bloated, foundered and finally wind-broken and blind.—*ibid.*

Do not commence farming with erecting costly buildings; but apply your time, efforts, and pecuniary means, to your farm; and shift on with tolerable accommodations, until your fields will warrant your providing better. Let your dwelling house and its appendages be to leeward as it respects commonly prevailing winds, (those in winter especially when fires are constant,) of your barn and stack-yard; and sufficiently distant from them to avoid accidents by fire.

Stables for horses should not be too close. Diseases are generated by confined air; and horses kept too warm cannot safely encounter cold and wet. Swine kept in too warm, and more so in filthy pens, are ever subject to diseases and unprofitable feeding. There is no greater mistake than that of gorging swine, when first penned for fattening. They should on the contrary, be moderately and frequently fed; so that they

be kept full, but do not leathe, or reject their food; and in the end contract fevers and dangerous maladies, originating in a hot and corrupted mass of blood; against some of which, dry rotten wood is an absorbent, and, some allege, smith's cinders, thrown in their pens are preventives. In airy and roomy, yet moderately warm pens, paved or boarded, and often cleaned, they are healthy and thriving. They show a disposition to be cleanly, however otherwise it is supposed; and they always drop their ejections in a part of the pen different from that in which they lie down. No animal will thrive unless it be kept clean.—*ibid.*

RYE.

A writer in the American Farmer says: "The great and the only secret with regard to insuring a good crop of Rye is EARLY sowing. From the middle of August to the middle of September, I have always found to be the best time for sowing Rye. From three pecks to a bushel per acre, is amply sufficient for seed. Early sown rye is much more heavy than the later; and further, it affords excellent pasture both in the fall and spring, nor does pasturing injure the crop; in many cases it is a real benefit—particularly when eaten down by sheep. Clover also succeeds much better after rye than after wheat."

BUTTER—HOW MADE.

The dairy house should be kept neat, should never front the south, southeast or southwest. It should be situated near a good spring or current of water. The proper receptacles for milk are earthen pans not lined or glazed with lead, or wooden trays. In warm weather milk should remain in the pail till nearly cool before it is strained, but in frosty weather it should be strained immediately, and a small quantity of boiling water may be mixed with it, which will cause it to produce cream in great abundance, and the more so if the pans or vats have a large surface.

In hot weather the cream should be skimmed from the milk at or before sunrise, before the dairy gets warm, nor should the milk, in hot weather, stand in its receptacles longer than twenty-four hours. In winter milk may remain unskimmed thirty-six or forty-eight hours. The cream should be deposited in a deep pan, kept in summer in a cool place, where a free air is admitted. Unless churning is performed every other day the cream should be shifted daily into clean pans, but churning should be performed at least twice a week, in hot weather; and this should be done in the morning before sunrise, taking care to fix the churn where there is a good draught of air. If a pump churn is used it may be plunged a foot deep in cold water, and remain in that situation during the whole time of churning, which will much harden the butter. A strong rancid flavor will be given the butter if we churn so near the fire as to heat the wood in the winter season.

After the butter is churned it should immediately be washed in many different waters, till it is perfectly cleansed from the milk; and it should be worked by two pieces of wood, for a warm hand will soften it, and make it appear greasy.

Butter will require and endure more working in winter than in summer.

Those who use a pump churn must keep a regular stroke: nor should they permit any per-

son to assist them unless they keep nearly the same stroke; for if they churn more slowly, the butter will go back, as it is called; and if the stroke be more quick, it will cause a fermentation by which means the butter will acquire a very disagreeable flavor.

Cows should never be suffered to drink improper water; stagnated pools, water wherein frogs spawn, common sewers, and ponds that receive the drainings of stables are improper.

The operation of churning may be very much shortened by mixing a little distilled vinegar with the cream in the churn. The butter being afterwards well washed in two or three changes of water. The whole of the acid will be carried off; or if any remain it will not be perceived by the taste. A table spoonful or two of the vinegar to a gallon of cream.

To take the rancid taste from Butter.

When fresh butter has not been salted in proper time, or when salt butter has become rancid or musty, after melting and simmering it, dip in it a crust of bread well toasted on both sides; and in a few minutes the butter will loose its disagreeable taste.

Butter made from scalded Cream.

As soon as the milk is taken from the cow let it be placed on a steady wood fire, free as possible from smoke, and scalded for thirty minutes—particular care must be taken not to let it boil. It must then be placed in a cool situation, and on the following day a thick rich cream will appear on the surface of the milk (which is excellent also for dessert purposes) this may be taken off and made into butter in the common way. This method is practiced in England, and it is said that a greater quantity of butter, and of a better quality can be made by this than by the common mode.

Receipt for curing Butter.

Take two parts of the best common salt, one part of sugar, and one part salt petre; put them up together so as to blend the whole completely: take one ounce of this composition for every sixteen ounces of butter, work it well into the mass and close it up for use.

BEER.

To fine and clarify Beer.

Put into a barrel a piece of soft chalk, burnt, about the bigness of two hen's eggs, which will disturb the liquor and cause it afterwards to be fine, and draw off brisk to the last, though it were flat before.—*Amer. Farmer.*

PUDDINGS.

To make a Ruta Baga Pudding.

One and a half pints of pulped Ruta Baga, two spoonfuls of wheat flour, four eggs, half pint of milk, and one table spoonful of butter. The pan greased and flowered, and baked with a quick fire.

Another Way.—One pint and a half of pulped Ruta Baga, a half pint of wheat flour, four eggs, a half pint of suet, and a pint of milk. The pan as before.

Another.—One pint and a half of pulped Ruta Baga, five spoonfuls of flour, a tea cup full and an half of beef marrow, three eggs, two tea spoonfuls of mace, and one pint and an half of milk. The pan greased as above.

It is said there has been a good crop of Hay in Maine, and that persons in Portland have offered to contract for the delivery of Potatoes at 9d per bushel.

FATTING CATTLE.—*From the Plough Boy.*

MR. HOMESLEY,
I have lately read an essay of Mr. Landon, of Connecticut, on what he deems the cheapest method of preparing cattle for the stall, the substance of which is here given.

In the winter of 1817, Mr. L. fattened an ox, and a heifer, in a way that he found cheaper than even common keeping. He fattened the heifer first. Her food for the purpose was chopped straw, scalded and seasoned with salt, to which was added a little meal of Indian corn and oats, and a small allowance of oil cake, or boiled flaxseed—the whole mixed up so as to form a mash. Of this about three pecks were given at a time. In fattening the heifer, she only eat a bushel of boiled flaxseed. Some boiled hay was also given her. The ox was afterwards fattened in pretty much the same manner, as nearly as we are able to understand the report of the two cases; for Mr. L. appears to have been more of an adept in fattening, than in describing the manner with clearness and precision. According to this account, however, it appears that his profits in pursuing this mode were very uncommon, and he says that the fattening of these cattle afforded him more clear profit than he had derived from all the cattle he had ever before fattened. It would seem, indeed, that he considerably more than doubled the price of his cattle in fattening them, and that the expense of it was very inconsiderable.

This being the usual time for commencing the business of fattening for the winter store, I have thought proper to exhibit the plan of Mr. L. from a belief that it is excellently adapted for fattening cattle with the least expense. It will readily be perceived, however, that the fall pasture is calculated to obviate the expense of using boiled hay; but I have no doubt that when good hay is steam-boiled, which may be done with a little expense, it is just as nutritious for cattle as when in its green state.

A PLOUGH BOY.**FARMER'S CAPITAL.**

There is, perhaps, nothing in which our farmers more frequently err than in undertaking to extend their farming operations beyond the reach of their means. The following remarks from Sir John Sinclair's Code of Agriculture, though written for Great Britain, will apply to this country, with such variations, and allowances for circumstances, as the good sense of the practical farmer will not fail to suggest.

It is indispensable for the success of every undertaking, that a sufficient capital to carry it on, should be at command; and for that of farming in particular. When there is any deficiency with respect to that important particular, the farmer cannot derive sufficient profit from his exertions; for he may often be obliged to dispose of his crops at an under value, to procure ready money; or he may be prevented from purchasing the articles he may require, though a favorable opportunity may present itself. An industrious, frugal and intelligent farmer, who is punctual in his payments, and hence in good credit, will strive with many difficulties, and get on with less money, than a man of a different character. But if he has not sufficient stock to work his lands properly;—nor sufficiency of cattle to raise manure;—nor money to purchase the articles he ought to possess, he must, under ordinary circumstances, live in a state of poverty

and hard labor; and on the first unfavorable season, or other incidental misfortune, he will probably sink under the weight of his accumulated burdens. In general, farmers are apt to begin with too small a capital. They are desirous of taking large farms, without possessing the means to cultivate them. This is a great error; for it makes many a person poor upon a large farm, who might live in comfort, and acquire property upon a small one. No tenant can be secure without a surplus at command, not only for defraying the common expenses of labor, but in case any untoward circumstance should occur. When a farmer, on the other hand, farms within his capital, he is enabled to embrace every favorable opportunity of buying with advantage, while he is not compelled if the markets are low, to sell with loss.

The amount of capital required, must depend upon a variety of circumstances; as 1. Whether it is necessary for the farmer to expend any sum in the erection, or in the repair of his farmhouse and offices; 2. What sum an incoming tenant has to pay to his predecessor, for the straw of the crop, the dung left upon the farm, and other articles of a similar nature; 3. The condition of the farm at the commencement of lease, and whether any sums must be laid out in drainage, enclosure, irrigation, levelling ridges, &c.; 4. Whether it is necessary to purchase lime, or other extraneous manures, and to what extent; 5. On the term of entry, and the period at which the rent becomes payable, as this is sometimes exacted, before there is any return from the lands out of the actual produce of which it ought to be paid; and, lastly on its being 1. a grazing, or 2. an arable farm, or 3. a mixture of both.

1. Grazing Farms.—In pasture districts, the common mode of estimating the amount of capital necessary, is according to the amount of the rent; and it is calculated, that in ordinary pastures, every farmer ought to have at his command, from three to five times the rent he has agreed to pay. But in the more fertile grazing districts, carrying stock worth from 30*l.* to 40*l.* per acre, (as is the case in many parts of England,) five rents are evidently insufficient. When prices are high, ten rents will frequently be required, by those who breed superior stock, and enter with spirit, into the new field of speculation and enterprise.

2. Arable Farms.—The capital required by an arable farmer, varies, according to circumstances, from 4*l.* 4*s.* to 10*l.* or 12*l.* per English acre. An ignorant, timid, and penurious farmer lays out the least sum he can possibly contrive; and thence obtains the smallest produce or profit, from his farm. These, however, will always increase, when accompanied by skill, spirit and industry, in proportion to the capital employed, if judiciously expended. At the same time, attention and economy cannot be dispensed with. It is ill-judged to purchase a horse at sixty guineas, where one worth thirty can execute the labor of the farm; or to lay out sums in expensive harness, loaded with unnecessary ornaments. Prudent farmers also, who have not a large capital at command, when they commence business, often purchase some horses still fit for labour though past their prime, and some breeding mares, or colts; and in five or six years, they are fully supplied with good stock, and can sometimes sell their old horses without

much loss. In every case such shifts must be resorted to, where there is a deficiency of capital.

3. A mixture of Arable and Grass Farming.—This, on the whole, is the most profitable method of farming. Independently of the advantages derived from the alternate husbandry, (which are always considerable,) the chances of profit are much more numerous, from a varied system, than where one object is exclusively followed. Where this mixed mode of farming is practised, the farmer will frequently rely on the purchase of lean stock, instead of breeding his own; and derives great advantage, from the quickness with which capital thus employed is returned. But, in that case, much must depend upon judicious selection.

It is not necessary to enter into any detailed estimates of the capital required for stocking arable or mixed farms, as they have been already detailed in former publications. In general it may be said, that to stock a turnip land arable farm, will require, at this time, from 5*l.* to 6*l.* and a clay land farm from 7*l.* to 8*l.* per English acre.

This capital is necessarily divided into two parts. The one is partly expended on implements, or stock of a more or less perishable nature, and partly vested in the soil; for this the farmer is entitled to a certain annual gain, adequate to replace, within a given number of years, the sum thus laid out. The other is employed in defraying the necessary charges of labor, &c. as they occur throughout the year; the whole of which should be replaced by the yearly produce. These two branches of expense on a farm, are the first to be attended to, both in order of time, and magnitude of amount.

The most satisfactory statement hitherto given, of the profit derived from the expenditure of an adequate capital in arable farming, is that furnished by George Rennie, Esq. of Phantassie, in East Lothian. On a mixed soil of 702 English acres, he states the profits at 1*l.* 5*s.* an acre, or about 14 per cent. on the capital employed. On this subject it has been well observed, that unless something commensurate to their skill, capital, and industry, is made by intelligent and industrious farmers, it would injure both the proprietors of land and the public. Adventurers who possess but little capital, would occupy the farms, probably at too high rents; they would exhaust the soil, instead of improving it; and while the rapacious landlord would be punished the public would suffer.

From the importance of capital to the farmer, it is evident, that where he unites prudence to energy, it would be of very great utility, to enable him to procure the use of capital, on as easy terms, as the manufacturer or the merchant. He ought to gain from 10 to 15 per cent. on the capital he lays out. He can easily therefore pay 5 per cent. for the money he may have occasion to borrow. As the best means of enabling him to give adequate security, it has been suggested, that the farmer shall have the power of sub-letting his farm, or assigning his lease, always securing a preference to the landlord on equal terms. A prudent farmer, of respectable character, would in that case, never want credit when necessary; and his difficulties regarding capital would in a great measure be done away. If this system were encouraged by liberal proprietors, persons possessed of ardent minds, and

a turn for agricultural improvement, with a power of sub-letting under reasonable restrictions, might go on improving one farm after another, and thus be the means of bringing extensive tracts of country, even in remote districts, into a productive state. But this plan cannot take place, where the tenant is not enabled, to pledge the improvements on his farm, as a security to his creditors.

From the American Farmer.

From a Series of Essays on Agriculture and Rural Affairs; by "Agricola," a North Carolina Farmer.

HORIZONTAL PLOUGHING

There is no improvement in agriculture which promises to be of more lasting benefit to our country, than horizontal ploughing.

Such has been the system of agriculture among us for ages past, that hilly or broken lands have been no sooner cleared, than wasted.

To test the correctness of this assertion, we need only cast our eyes over the different parts of our country, to behold thousands of acres of hilly land rendered entirely barren, not so much from the vegetable nutriment being extracted by the crops cultivated thereon, as from the soil itself being washed away and deposited in low and sunken places, creeks, rivers, &c.

What would be the consequences of such a system of Agriculture, if it admitted of no remedy or improvement? As a great part of the United States consist of hilly or broken land, the consequences would not only have terminated in the destruction of the soil; but would have extended to the impoverishment of half a nation, and even the destruction of navigation itself.

I do not, therefore hesitate to believe, that horizontal and deep ploughing, promise to be the salvation of our hilly lands, particularly if combined with enclosing, the use of Plaster of Paris and Red Clover.

Horizontal Ploughing was first introduced into practice in this country by Colonel Randolph of Virginia, son-in-law to Mr. Jefferson. Mr. Jefferson, who has frequently witnessed the great and beneficial effects, resulting from this practice, not only on the farm of Col. Randolph, but also on his own, thus details the mode of horizontal ploughing in a letter to a distinguished farmer in Massachusetts, and published in the Agricultural Repository:

Horizontal Ploughing has been practised here (Virginia) by Col. Randolph, my son-in-law, who first introduced it, about a dozen or fifteen years ago. Its advantages were so soon observed that it has already become very general, and has entirely changed and renovated the face of our country. Every rain before that, while it did a temporary good, did greater permanent evil, by carrying off our soil, and fields were no sooner cleared than wasted; at present, we may say that we loose none of our soil—the rain not absorbed in the moment of its fall being retained in the hollows of the beds until it can be absorbed. Our practice is, when we first enter on this process, with a rather level of ten feet span, to lay off guide lines, conducted horizontally around every hill side, and about thirty yards apart; the steps of the level on the ground are marked by the strokes of a hoe, and immediately followed by a plough to preserve the trace; a man, or a boy of 12 or 15 years old with the level, and two smaller boys to mark the steps, the one with sticks, the other with the hoe, will do an

acre of this in an hour, and when once done, it is forever done. We generally level a field the year it is put into Indian corn, until all have been once levelled: the intermediate furrows are run by the eye of the ploughman, governed by these guide lines, and is so done as to lay the earth in horizontal beds of 6 feet wide with deep hollows or water furrows between them, to hold superfluous rain—the inequalities of declivity in the hill will vary in places the distance of the guide lines, and occasion gorges, which are thrown into short beds.

I have transferred this method of ploughing to a possession I have near Lynchburg 90 miles to the S. W. from this place, where it is spreading rapidly, and will be the salvation of that, as it confessedly has been of this part of the country.

Horizontal and deep ploughing, with the use of plaster and clover, which are but beginning to be used here, we believe will restore this part of our country to its original fertility, which was exceeded by no upland in the State."

As many persons may not have a correct idea of the raster level, the use of which is recommended in this Essay, the Editor has procured the annexed engraved representation of it.

It is necessary to caution the reader, that unless horizontal ploughing be correctly done, it had better not be done at all; because I have observed that many have attempted this mode of ploughing, without understanding its principles: If the water furrows, which are intended to hold the superfluous water, have the least descent one way or another, they will have the effect of throwing the water to one point, where such a quantity will be collected in heavy rains by a number of water furrows leading to the same point, as will inevitably produce a breach thro' the ridges. It is advisable, that before the level is applied to a field its surface be made as even as possible; this is best done, if its unevenness renders it necessary, by flushing up the ground in the fall or winter with a mould board plough, and early in the spring to be well harrowed with a two horse harrow; this last operation will not only level the surface, but will have the additional valuable effect of breaking the clods and thereby effectually pulverizing the ground, which will prove of great advantage to the corn in every stage of its growth. The level, in this case, may be applied in the spring and the ground listed or thrown into horizontal drills for the planting of the corn. Success in horizontal ploughing depends on the exactness of the level to suspend, and the depth of the ploughing to absorb the water. Enclosing is indispensably necessary to make it beneficial, as by that the earth is brought into a

proper state for absorbing more water, and the suspension of the progress of this water by a vegetable cover, allows more time for the operation of absorption.—In heavy rains, when the ground is in cultivation, and however accurately levelled, instances will occasionally occur breaches across the horizontal beds.—The remedy is, to fill them immediately with brush, having the leaves on, well packed.

These instances, however, are very rare and easily thus cured.

Besides the inestimable advantage from horizontal ploughing in protecting the soil against the wasting effect of rains, there is a great one in preventing the rains themselves from being lost to the crop. The Indian corn is the crop which most exposes the soil to be carried off by rains; and it is at the same time the crop which most needs them.—Where the land is not on hilly, but the soil thirsty, (as is generally the case with such lands) the preservation of the rain as it falls between the drilled ridges, is peculiar importance; and its gradual settling downwards to the roots, is the best possible mode of supplying them with moisture. In the old method of ploughing shallow up and down hill, the rain as well as the soil was lost, which not only destroyed the upland, but rushed down and poisoned the valleys. The result of horizontal ploughing in Virginia is extremely encouraging to those who may wish to adopt the practice here. Farms there which are very hilly, whose soils were particularly liable to be washed away, and which were excessively galled and gullied, have been relieved probably nineteen parts in twenty of those calamities by horizontal and deep ploughing in combination with inclosing.

NEW ENGLAND FARMER.

BOSTON.—SATURDAY, AUGUST 10, 1822

THE SCIENCE OF AGRICULTURE AND BOOK FARMING

Agriculture, the oldest of the arts, considered as science, is still in its infancy. It is, we believe, fifty years since chemistry was brought to the aid of agriculture, and this will eventually prove one of its principal pillars. Systematic Rotations of crops—Improvements in breeding cattle—the use of Plaster Paris—Soiling of Cattle—the extensive Field Culture of Roots, for the purpose of feeding cattle—Artificial Grasses, &c. &c. are of modern date, and have brought about great revolutions in the theory and practice of farming. The practical farmer, especially in the old and more populous parts of the country, must understand, and in some degree practice these improvements or he will not only neglect to make the most of his means but probably make so many backward & down-hill movements in the journey of life, that, ten chances to one old age will find him in the vale of poverty. The cultivator who does not keep pace with his neighbors regards agricultural improvement and information, will soon find himself the poorer in consequence of the property that surrounds him. He will be like a stunted oak in a forest, which is deprived of light and air by its more towering neighbors. For instance, A. find out a mode of managing by which he can raise 30 bushels of potatoes with as little expense as B. can raise 200 bushels of the same root. A. can not only undersell B. and thus injure him as an individual rival, but after a while Messrs. C. D. E. F. and so on to the end of the alphabet, adopt A's mode of culture; the market price of potatoes is reduced, B. can no longer afford to raise them for what they will fetch—his occu-

tion is gone, and it is to be feared that he must go with it, either to a poor-house or the state of Ohio.

But we would not advise farmers in middling circumstances to make expensive experiments, nor adopt novelty in husbandry on slight grounds, without being well convinced by testimony, observation or experience, of its beneficial effects. We had better by all follow the beaten track of our ancestors, if it be a little rugged and circuitous, than strike out at once into a wilderness of whim-whams, and theories not sanctioned by actual and repeated experiments. A farmer, unless he be very rich indeed, cannot afford to be "full of notions," but must leave merchandize of that sort to the good citizens of the Metropolis. He should exercise his own good sense on every proposed improvement, and neither consider that it *must* be useful because it is new, and has the sanction of some great names, nor let its novelty be an insuperable objection to its adoption. Many plants, animals, and theories relating to agriculture, &c. which some years since were considered as very useful and meritorious, are now deridedly sunk in public estimation; and those who adopted or introduced them have suffered in consequence of their anticipations not having been realized. Thus the theory of Tull, by which frequent ploughing as to supersede the use of manure; the Lombardy poplar, which was supposed to be more useful and ornamental than any of the countless species of trees which adorn our forests—the Burnet-grass, which was presented as the grass which must eventually root it all other grasses, have had their day and their advocates, and some ardent theorists have undoubtedly suffered in consequence of their carrying into practice their predilections in favor of this or that plant, or plan of cultivation. These things, however, should not check enterprise, but inspire caution, and teach us that at every novelty may not be an improvement, although *very improvement was once a novelty*.

Some farmers tell us that they never knew any good result from what they call *book-farming*. That *gentlemen farmers*, who know nothing about farming but that they get out of their libraries spend a great deal, it never make any profit by their agricultural projects, and schemes of domestic economy. We will examine these positions a little.

It was truly said by Lord Bacon that "*Knowledge is power*." This maxim applies with as much force to agriculture as to any thing which can be the object of human agency. If we *knew* nothing we could effect nothing beneficial to ourselves or others, but must burrow in the ground and subsist upon beech nuts, and then spontaneous productions of the earth. This knowledge, which gives man his supremacy "over the beasts of the field and the fowls of the air," and which bestows on individuals among mankind a pre-eminence much more substantial and less invidious than birth, wealth, titles, or popular applause, can be acquired only by three modes, viz. *observation, conversation and reading*. Observation and conversation are very important inlets to ideas, and reading furnishes perhaps, as great a quantity of useful materials for the mind to operate upon as either of them. *Book-knowledge then is power*, and other things being equal, the farmer who obtains information from books, or other printed works, and has strength of mind, and good sense sufficient to make a proper use of it, has the advantage over his unlettered neighbor, who despises book farming, equal perhaps to one pair of hands and two yokes of oxen. Besides, what is this book knowledge, which some honest cultivators think is so much to be derided? It is nothing more than the result of observation, or experience, which after having passed through the channel of conversation, is at length re-

duced to writing, sent to the press, and the moment it is printed, becomes, according to the objectors to whom we allude, *book farming*; and therefore is to be considered as something very ruinous to the practical husbandman! Thus, we will suppose that A. has found out a safe and easy cure for bots in horses, or an antidote against the Hessian fly, or a method by which he can raise double the usual quantity of Indian corn on an acre; A. communicates his discovery or improvement to B. his near neighbor, who, although he has a great aversion to book farming, makes use of and derives great advantages from it on the strength of A's oral testimony. But A. sends an account of his discoveries and processes to the printer, and it is published in some periodical paper, and perhaps finds its way into some volume written on agricultural subjects. The whole then becomes *book farming*, and not worthy of the attention of real, genuine, practical farmers!

But these absurdities are fast yielding to reason and the lights of science. The time has arrived in Europe, and is fast approaching in America, in which books, and the information which they contain, will be considered as necessary to make a man a complete farmer, as a complete physician, lawyer or divine.

THE SEASON.

We believe that the present season bids fair to be quite as fruitful as usual. The early drought has been succeeded by copious rains, and for some days past cool and pleasant weather has afforded the farmer an excellent opportunity to gather the products of the fields. Grass-hoppers and other devouring insects are not so common nor destructive as they have been for several summers past, and there is every prospect that the year will be crowned with the goodness of the great Bestower of all benefits.

A late arrival from Liverpool at New York furnishes London dates to the 22d June. By these we learn that several bills, annihilating the long continued navigation system of England, have passed through Parliament, and of course a free trade will be allowed to every part of the British dominions, including the West India Islands. This will give fresh stimulus and energy to commerce and navigation, as well as to agriculture and every other species of laudable industry.

The war between Russia and Turkey seems to be suspended for the present, and perhaps will be adjourned without day. Those, therefore, who long for something sanguinary and terrible, will probably have their depraved appetites balked, and must be satisfied with such calamitous accidents by flood and field as these "piping times of peace" can afford us.

The situation of the Greeks, it is to be feared, is desperate. The Emperor of Russia, it is said, refuses to interfere in their behalf, and they suffer all that those can inflict whose tender mercies are cruelty.

There is some vaporing in foreign journals about fighting between France and Spain, but we are inclined to think that the rumors of war were got up for pecuniary purposes, either to accomplish some stock jobbing manoeuvre, or to give interest to the dull columns of newspapers destitute of news.

A Naval Court of Inquiry, at the request of Captain Hull, will commence at the Navy Yard on Monday next. The members are Captains Rodgers, Chauncy, and Morris. The two former are Navy Commissioners.

A highway robbery was committed 14th Tuesday night, between 11 and 12 o'clock, near the draw-bridge, in Fore Street, on a young man, who was knocked down by the highwayman, and rifled of his pocket-book, containing one \$10 bank note, and several others of a smaller denomination.—*Evening Gazette*.

On Wednesday, Ticket No. 1245, which drew the Capital Prize of \$2,000, in 3d class of Canal Lottery, was presented, and paid by Benj. Huntington, No. 21, Exchange st.

Hill, who was wounded in the late insurrection at the State Prison, died on Sunday last.

At New Brunswick lately four persons were poisoned by eating muscles—and two of the persons died.

PRODUCTS OF AGRICULTURE.

The amount of the product of the well cultivated lands of the Eastern States, would astonish any but those who have been accustomed to the river bottoms on the western rivers, or to alluvial lands. We can scarcely believe when we read them; and should not believe it, were not the facts too well vouched to be questioned. We lately met with an account of the premiums given at a Massachusetts meeting some time last autumn, and a few of the results are stated below, for the gratification of the curious in such matters.

Of Potatoes.—Five hundred and fifty-one and a half bushels were raised on one acre of land, by Payson Williams, Esq. of Fitchburg, in the county of Worcester, (from 21 bushels of seed.)

Of Turnips.—Seven hundred and fifty-one bushels of the common English sort, weighing 51 lbs. to the bushel, were raised by Messrs. T. & H. Little, on one acre of ground.

Of Mangel Wurtzel.—Six hundred and forty-four bushels were raised on one acre of ground, by John Prince, Esq. of Roxbury.

Of Cabbages.—Forty-three tons nineteen hundred and ten pounds weight, were raised by E. H. Derby, Esq. of Salem, on one acre, one quarter of an acre, and twenty-seven rods, being at the rate of thirty-one tons to the acre.

Mr. Derby received also the premium of \$30 for having raised the greatest quantity of vegetables, (grain, peas and beans excepted) for winter consumption of the stock on his own farm. He raised the last season on his farm 749 bushels of mangel wurtzel, 530 bushels of carrots, 526 bushels Swedish turnips, 1238 bushels of potatoes, 126 bushels of Russian radishes, 757 bushels of common English turnips, 23 tons and 19 cwt. of cabbages, and 15 ox cart loads of pumpkins.

Of Ruta Baga.—Mr. David Little raised six hundred and eighty-eight bushels on one acre.

Of White Beans.—Thirty-two bushels and four qts. were raised on one acre by William Mears, of Marblehead.—*National Intelligencer*.

THE DUELISTS—A TRUE STORY.

We learn an affair of honor recently took place in this vicinity, between the heroic wife of ensign W. and one of the veteran marines of the illustrious Preble. The parties, instead of using swords and pistols, supplied their hands with weapons more innocent and less honorable, from the odoriferous contents of a *pig sty*;—and disdaining to stand *Cumming* and *Macduff* like, boldly faced each other. The contest was continued with great spirit, and the *utmost politeness*, on both sides, till the locks and garments of either party dripped with liquid odour; and till the fair antagonist fell under the well directed fire of her adversary, and was declared unable to maintain the combat any longer. We are happy to learn that she is "perfectly comfortable;" and that the unquenched animosity of the parties rekindled by the officious intermeddling of the mischief-making public, will probably afford us a renewed exhibition of their martial spirit. Indeed, it is currently reported that a second challenge has been sent and accepted—the official bulletin announcing the same is hourly expected, the result of which we shall wait with as much anxiety as of that which is to take place on the 10th inst. at the South; and we doubt not the parties will retire from the field of combat *equally covered with honor*.—*Salem Gazette*.

DEATHS.

In this city, Mrs. Hannah Farrar, wife of Mr. John A. F. 36.—Miss Mary Waterman, 19.—Mr. William Badger, 80.—Mr. John Lloyd, 39.—Martha Esther, daughter of Ebenezer and Dolly Hill, 2 yrs. 6 mo.

GREAT ADDITIONS TO THE NEW ENGLAND MUSEUM, 76, COURT STREET.

THE Proprietors of this extensive establishment have the pleasure to announce to their patrons and the public, that, besides their usual continual additions of curiosities from all parts of the World, they have just added another *entire Museum*, making now one *Grand Consolidation, of 4 Museums united in one*.

The late additions alone are superior in extent and variety, to any other Museum in this city.

Admittance 25 cents only.

August 10

AGRICULTURE.

Thou first of arts, source of domestic ease,
Pride of the land, and patron of the seas;
Thrift Agriculture! lend thy potent aid;
Spread thy green fields where dreary forests shade;
Where savage men pursue their savage prey;
Let the white flocks in verdant pastures play;
From the bloom'd orchard and the showery vale
Give the rich fragrance to the gentle gale;
Reward with ample boon the laborer's hand,
And pour the gladdening bounties o'er our land
Columbia's sons, spurn not the rugged toil,
Your nation's glory is a cultur'd soil.
Rome's Cincinnatus, of illustrious birth,
Increased his laurels while he till'd the earth.
Even China's monarch lays his sceptre down,
Nor deems the task unworthy of the crown.

THE MILK-MAID AND THE BANKER

A Milk-maid with a very pretty face,
Who liv'd at Acton,
Had a black Cow, the ugliest in the place,
A crooked-back'd one,
A beast as dangerous too, as she was frightful,
Vicious and spiteful,
And so confirmed a truant, that she bounded
Over the hedges daily, and got pounded.
'Twas all in vain to tie her with a tether,
For then both cord and cow clod'd together.

Arm'd with an oaken bough (what folly!
It should have been of birch, or thorn, or holly.)
Patty one day was driving home the beast,
Which had, as usual, slipp'd its anchor,
When on the road she met a certain banker,
Who stopp'd to give his eyes a feast
By gazing on her features, crimson'd high
By a long cow-chase in July.

"Are you from Acton, pretty lass?" he cried;
"Yes," with a courtesy, she replied.
"Why then you know the laundress, Sally Wrench?"
"She is my cousin, sir, and next door neighbor."
"That's lucky, I've a message for the wench,
Which needs despatch, and you may save my labor.
"Give her this kiss, my dear, and say I sent it,
"But mind, you owe me one—I've only lent it."
"She shall know," cried the girl, as she brandish'd
her bough,
"Of the loving intentions you bore me,
"But as to the kiss, as there's haste, you'll allow
"That you'd better run forward, and give it my Cow,
"For she, at the rate she is scampering now,
"Will reach Acton some minutes before me."

THE LAWYER AND THE CHIMNEY SWEEP.

A renegade old Lawyer was planning new sin,
As he lay on his bed in a fit of the gout;
The mails and the day-light were just coming in,
The milk-maids and rush lights were just going out:
When a chimney-sweep's boy, who had made a mistake,
Came flop down the flue, with a clatter and rush,
And bawl'd, as he gave his black muzzle a shake,
"My master's a coming to give you a brush."

"If that be the case," said the cunning old elf,
"There's no moment to lose—it is high time to flee;
"Ere he gives me a brush I'll brush off myself,
"If I wait for the devil, the devil take me!"

So he limp'd to the door, without saying his prayers,
But Old Nick was too deep to be nick'd of his prey,
For the knave broke his neck by a tumble down stairs,
And thus ran to the devil by running away.

APHORISMS.

To bear and forbear is the grand surety of
happiness, and ought to be the grand study of
life. It is that "charity which suffereth long,
and is kind, and is not easily provoked."

Some persons say severe things at random,
without appearing at all conscious of the wounds
which they inflict by

"—The word whose meaning kills, yet told,
The speaker wonders that you thought it cold."

The strongest of all ties is the consciousness
of mutual benefit and assistance.

It is too true that wounds, however small,
which are inflicted on our self-love are never
forgotten, and rarely forgiven; and it is safer to
censure the morals of our acquaintance, than to
ridicule their dress, a peculiarity in their man-
ners, or a fault in their persons.

We are all of us too apt to repeat stories to
the prejudice of others, even though we do not
believe them. Well indeed does St. James say
that "the tongue is an unruly member."

Whatever may be the ill conduct of a hus-
band, that wife must be deluded indeed, who
thinks his culpability an excuse for hers, or seeks
to revenge herself on her tormentor by follow-
ing the bad example which he sets her. She
is not wiser than the child, who to punish the
wall against which he has struck his hand, dash-
es his head against it in the vehemence of his
vengeance, and is himself the only sufferer by
the blow.

There is nothing more dangerous to the vir-
tuous and to the interests of virtue, than associa-
tion with the guilty who possess amiable and at-
tractive qualities.

Opportunities for conferring large benefits,
like bank bills of \$1000, rarely come in our way,
but little attentions, friendly participations, and
kindnesses are wanted daily, and like small
change are necessary for carrying on the busi-
ness of life and happiness.

Many a conjugal union, which has never been
assailed by the battery of crime has fallen a sac-
rifice to the slowly undermining power of petty
quarrels, trivial unkindnesses, and thoughtless
neglect.

Attention to decorum is one of the greatest
bulwarks of female virtue.

It is a painful but well known fact that the
envy and rivalry of near relations is the most
bitter and inveterate.

All persons given to anger are apt to dwell on
the provocation that they have received, and
utterly forget the provocation they gave.

ANECDOTES.

When Themistocles was a boy, he was on a
certain time returning from school. Pisistratus
happening to meet him, the master said to The-
mistocles, "stand out of the way, and give place
to the prince." "What," said Themistocles,
"has he not room enough?" thus intimating
the little respect he paid to a tyrant.

Some people are proud of dress, others are
proud of their singularity. Some are proud of
being extravagantly *in*, and others of being ri-
diculously *out* of fashion. Some are proud of
their *humility*. A Greek philosopher being at
a celebrated festival saw some young men of
Rhodes magnificently arrayed. Smiling he ex-
claimed "this is pride." Afterwards meeting
some Lacedaemonians in a mean and sordid dress
he said "and this also is pride."

In England, it is well known that the Yan-
kees are ridiculed with the name of *Bumpkins*.
An English lady, on a tour through the northern
part of this country, passing a field of pumpkins
enquired what they were? Her companion re-
plied that they were *pumpkins*. "*Barbarous
wretches*," exclaimed the lady, (mistaking the
name for *bumpkins*.) "*barbarous wretches, to
bury their friends with their heads out of ground*."

FILTER PUFF—AUCTIONEER,

Dyer and Man Milliner—mends clocks and
makes wigs; tunes piano fortes and cuts corns
man-midwife and horse-shoer; bellows-maker
and teacher of psalmody; has a diploma from
Gretna Green, and another from the University
of Aberdeen; attends at all times and places
from break of day till three o'clock the next
morning to unite the votaries of Hymen, inocu-
late children, bleed horned cattle and other
reptiles; rings pigs noses and the parish bells
and performs all kinds of manual operations by
steam, water, and thirty-ass-power, without
touching hand or foot to the machinery.

Irish paper.

A gentleman in *Cork*, of much taste fitted up
a house in a style of great elegance. On show-
ing it, however, to a friend, the latter objected
to the thinness of the partitions, which divided
the rooms from each other, observing that al-
though that was said in one room might be heard in the
next. To this the owner replied that he would
immediately try the validity of the objection by
an experiment which would not fail. He ac-
cordingly called his servant Patrick, directed
him to go into the next room, to carefully shut
the doors, and then listen in order to ascertain
if he could distinguish any words spoken in the
other room where his master remained. When
the master thought Pat was properly stationed
he called out to him "do you hear me?" Pa-
trick answered "no Sir."

New Printing Office.

(↗ Entrance Nos. 4 and 11.

Husbandman and Housewife.

FOR sale at the Bookstore of Charles L.wer, No. 51
Munroe & Francis, No. 4, Cornhill, and at this
Office:—THE HUSBANDMAN AND HOUSEWIFE
being a collection of valuable Recipes and Directions
relating to Agriculture and Domestic Economy. By
THOMAS G. FESSENDEN, Esq. Price 50 cents.

The following notice of this work is extracted from the
Massachusetts Agricultural Journal for June 1822.

"We have read it with attention, and think it well
adapted to the use of farmers, who would not go to the
expense of purchasing larger works. It is a collection
of receipts, many of which are from high authority, and
all of them, as far as they are accurate, calculated for
daily and constant use. That errors should creep into
such a work must be expected. The recipes are often
taken from such transient works, or sources, that it
would be impossible for the compiler to vouch for their
efficacy or exactitude—but still its use must be very
great to the class of people for whom it was principally
intended."

No. 3.

From the American Farmer

the immense importance of durable timber for farming as well as naval purposes, gives an interest to every judicious, or even plausible speculation on the subject. The communication from a person of Commodore Porter's intelligence, will of course attract attention: especially when viewed in connexion with his official station, which peculiarly demands the best attainable knowledge of the matter. Believing the opinion he has given, which is, and probably has been for ages that generally received, to be erroneous; and thinking it possible that I might throw some light on the subject;—I submit to your readers the following observations on the

FELLING OF TREES FOR TIMBER.

In the 22d number, volume III, of the American Farmer, is a letter from D. Porter, (Commodore Porter) on "The best time to fell Timber with a view to its durability"; in answer one from the Editor, requesting a communication on the subject. The commodore, "availing himself (as he says) of the knowledge and experience of others, in support of his opinion," states this to be, that "the most proper season for felling timber with a view to its durability, is in the winter, when the sap has ceased to circulate." This corresponds with the opinion I have heard generally expressed, ever since I noticed observations on the subject; and the precise time in the winter is fixed, by tradition, to the old of the moon in February."

Many years (perhaps half a century) have elapsed, since I have been inclined to doubt whether the animal and vegetable kingdoms are under the government of the moon. The commodore thinks its "influence nearly if not quite as powerful as [that of] the sun." He asks, "why that body [the moon] whose attractions can raise the tides and influence all animal creation, should not have the power to put the sap of vegetables into circulation, assisted as it is by capillary attraction?"—As heat is essential to give motion to the sap in plants, and the heat of the sun is adequate to that effect, it is not necessary to seek for any other cause; still less to resort to one merely conjectural. No means yet tried have discovered any heat in the rays of light from the moon.

If any effects on vegetation were ascribable to the moon's attraction, yet in an entire revolution, at different distances are not so considerable, as to produce very different effects. Besides considering its different periods, it is as near the earth in its decrease, as in its increase; and its power of attraction must be the same in both cases. The sowing of seeds, therefore, and their vegetation, and the growth of the plants proceeding from them, cannot, (as the commodore seems to suppose) be influenced by the phases or appearances of the moon. The notion of the moon's "influence on all animal creation," if not a novelty, I believe to be altogether visionary. Anciently, indeed, mad people were supposed to be affected or influenced by the moon; and hence were called lunatics: but that opinion seems now to be exploded. I am indeed satisfied (contrary to the general belief) that changes in the weather have no dependence on the moon; but happen indifferently at all periods of its increase and decrease. It has not heat to raise wa-

tery vapours from the earth, or to suspend them in the air; and under the same aspect of the moon, the weather is fair at one place and foul in another.

No one can doubt that "dryness is favorable and moisture unfavorable to the durability of timber;" and in winter the sap of trees is probably inspissated to a considerable degree; but no living tree is then "devoid of sap."—The important question, therefore, in relation to the felling of timber trees, is, I am inclined to think, not simply when trees have the smallest quantity of sap; but at what season the sap they contain will most easily escape or be expelled. The facts I am going to state may show this to be in the spring, when the sap is thinnest and flowing in the greatest abundance.

In the year 1800, divested of public employment, and about to commence husbandman, I made a visit to the late Joseph Cooper, of New Jersey, one of the most intelligent farmers I ever knew, to converse with him on the subject of his vocation. Among other things, he spoke of timber; and stated the following facts. His farm lying on the Delaware river nearly opposite to Philadelphia, was exposed to the ravages of the British army while occupying that city. Pressed for fuel, his fences first fell a prey to their necessities. In the month of May 1778, they cut down a quantity of his white oak trees: but circumstances requiring their sudden evacuation of the city, his fallen timber was saved.—The trees he split into posts and rails. The ensuing winter, in the old of the moon in February, he felled an additional quantity of his white oaks, and split them also into posts and rails to carry on his fencing. It is now, said he two and twenty years since the fences made of the May-felled timber were put up, and they are yet sound; whereas those made of the trees felled in February, were rotting in about 12 years. He then pronounced confidently, that the best time for felling timber trees, for durability, was when their sap was vigorously flowing. He said, also, that white oak and hickory trees felled at that season, would not be attacked by the worms, producing what is called "powder post." And added that hoop-poles of oak and hickory ought, for this reason to be cut the same season.

In the same year, accident threw in my way the late Oliver Evans' book on the construction of mills; to which was subjoined a treatise of a Mr. Ellicot, a millwright, on the same subject. Turning over some of the leaves of this treatise, I lighted on the passage in which the author directed hickory timber, intended for the cogs of wheels, to be cut when the sap was running, that they might not become powder post.—In the following winter (1801) being in Boston, and conversing with a friend from the country on subjects of husbandry, I repeated Mr. Cooper's observations, as above stated. This friend then mentioned a farmer, the well pole (or sweep) of whose well happened to break at a very busy time: that to supply its place, he cut down the first small tree that came to hand, and this was a white birch. The sap then running freely, he stripped off the bark, and put up his pole; and it lasted seventeen years. Had he put it up

with the bark on, it would probably have rotted in a year; the closeness of the birch bark preventing the escape of the sap. A close coat of paint, laid on unseasoned wood, operates like the close birch bark, by confining the sap, and hastening its decay.*

More than fifty years ago, seeing a quantity of logs with the bark on, piled up by a chair maker's shop, I asked him why he did not split them, that they might the sooner get seasoned. He answered, that so long as the bark remained on the logs the sap remained in them, and they were more easy to be dressed and turned. Unless timber trees be cut when the sap is running, the bark cannot be stripped off; tho' with considerable labor it may be removed by the axe and drawing knife; but less perfectly.

The late Mr. Bordley (who was vice-president of the Philadelphia Society of Agriculture, from its formation in 1785, until his death) once told me, that when riding in the vicinity of Philadelphia, he met a master ship-builder, who had been viewing some trees for ship timber. Mr. Bordley mentioned to him the greater value of ships built with the timber of trees allowed to remain standing a length of time after their bark had been stripped off. The shipwright said he was fully sensible of it; the ships would last so much longer. Why then, asked Mr. Bordley, do you not adopt that practice? Because, said the shipwright, such timber becomes very hard, and costs much more labor to work it.—I have heard new settlers dispute, which was the best way of clearing woodlands; whether by girdling (chopping the bark all round the trees to stop the circulation of the sap, when they gradually die) and letting the tree stand; and at once seeding the land for a crop: or by cutting all down at first, and burning. The advocates of the latter mode, said, that by girdling and letting the trees stand, they became dry, and so hard as greatly to increase the labor of afterwards cutting them down.

"Dr. Plott [who wrote in the 17th century] says, it is found by long experience, that the trunks or bodies of trees when barked in the spring, and left standing naked all the summer, exposed to the sun and the wind, are so dried and hardened, that the sappy part in a manner becomes as firm and durable as the heart itself. This is confirmed by M. Buffon, who in 1738, presented to the Royal Academy of Sciences at Paris, a memoir, entitled "An easy method of increasing the solidity, strength and duration of timber;" for which purpose he observes, "nothing more is necessary than to strip the tree entirely of its bark during the season of the rising of the sap, and to leave it to dry before it be cut down."†

* In confirmation of the opinions advanced by Col. Pickering, we can add, that poles cut from the green willow, the tenderest and least durable of our trees, in June, and stripped, became extremely tough and hard, so as to be applicable to many uses, such as ladders, &c. for which spruce is used. The loppings of all trees cut off in June become extremely hard, and will endure for years without rotting. These we know to be facts.

EDITORS.

† See British Encyclopædia, article Tree; also Rees' Cyclopædia, article Timber.

But why should timber trees be felled in May, (or when the sap is freely running,) as in the case stated by Joseph Cooper; or barked and left standing until dry, according to Buffon, be more durable than timber felled according to the prevailing & popular notion, of the old of the Moon in February? For an answer I offer the following conjecture.—The thinner and more fluid any body is, the sooner and more perfectly it will evaporate. The sap of trees is doubtless more inspissated, or of thicker consistence, in winter than in the spring, when it is apparently thin and watery. In the latter state it will find its way, and escape, through the pores of the wood, with vastly greater ease and expedition than when, as in winter, it is much inspissated. Molasses, condensed by the winter's cold, runs very slowly through tubes of a large size. In summer, the same molasses swelling to a large volume, and becoming very thin, will pass through very small tubes, and, I believe through the pores of some sorts of wood. The same substance (molasses) exposed, in a small quantity, to the hot sun of summer, would soon discharge its more fluid parts, and at length leave, as I suppose, a solid substance behind; but if much diluted with water, would not the whole substance be nearly if not quite carried off by evaporation?—the same reasoning may apply to trees left standing, after being divested of their bark in the spring.

It appears by some English books that their usual time for felling oaks is in the month of April, when the sap is running, and they can strip off the bark for tanning. But the commodore states, “that in all their contracts for timber for naval purposes, the influence of the moon on the sap is more guarded against than any other;” and he adds, what seems very extraordinary, that “more attention is paid to the time of the moon when timber should be cut, than to the season of the year; for (as before remarked) seeing the moon is at the same distances from the earth during its decrease as its increase, its power of attraction must be the same in both cases; and consequently all the different effects which tradition has ascribed to the waning and the waxing moon must be visionary.

The maturity of timber is quite another thing; and probably of more importance than the time of felling it. There is a point of *ripeness* when trees acquire their greatest solidity, strength and durable quality for timber. The late Dr. James Anderson,* says—“It is now well known that the best fir timber which comes from Riga, and other places on the Baltic, is the produce of the same tree that is commonly cultivated here [in Scotland] under the name of the *Scotch fir*; but having grown more slowly in those countries than the planted trees do here, and having been allowed to attain a much greater age, that wood is beyond comparison closer and four times or least more durable, in any kind of work, than the young *raw* deals [boards and planks] which are made of wood the usual growth of this country.

Dr. Anderson, in early life a practical farmer, a man of letters, and an ingenious and philosophical observer of nature, appears, nevertheless, to be entirely mistaken in his ideas of the cause of the hardness and strength of wood, and in ascribing to the same cause in part, its durability. Mentioning the rings in trees which

mark their growth, he says—as one of these rings is added to the circumference of the tree each year of its growth and forms the whole increment of the tree for that year, it follows, that the less that increment is, or in other words, the slower the trees grow, the less will be the breadth [thickness] of these rings, and of course, the closer the grain of the wood, and the harder also it will be.” Just the reverse of this is the fact. Every farmer and carpenter, in the United States, knows that the thicker the annual ring, or, in the common language, the larger the grain, the harder and stronger is the wood. Hence the butt-ends of white oak are preferred for the spokes of wheels, and of hickory for axe helvies. Every wood-chopper also knows how much easier it is to fell and cut up the trees growing with small grains in a close forest, than trees of the same kinds which have grown singly and faster in open grounds. And every man who has used husbandry tools, a fork or rake for instance, whose handles are of ash, knows how much harder, stronger, and heavier, because more solid, they are when made of timber with large grains, which had grown fast in good soils, or at such distances from tree to tree as not to rob one another of their food,—than when of small grained slow growing timber. But the timber of trees, pasture oaks for instance, standing singly and at distances from others, and which are of rapid growth and consequently with large annual rings, or grains, though twice as tough and strong, is found, I have long understood less durable than the timber of oaks of slower growth. The reason is obvious. The oaks in forests do not attain the sizes fitting them for ship timber, until they have reached the age of maturity or ripeness. In this state they may probably continue stationary for some years; but if left standing for many years after they are of full age, the toughness and strength of the wood are greatly impaired. But pasture or other fast growing oaks, attaining, in much fewer years, sizes suitable for ship-building and other uses, are sometimes cut down before they come of age, before they are mature, or perfected by time; and hence the early decay of such timber. The fact stated by Dr. Anderson, in comparing the *raw* Scotch and the mature Baltic firs, exemplifies this doctrine. And in correspondence with it, I will mention a maxim which probably had been handed down from generations, and was repeated to me by my father when I was a boy, upwards of sixty years ago, which I perfectly remember, and have repeated to others: “My father used to say (so the maxim was introduced to me) young wood for fire, old wood for timber.”

In reference to the memoir of M. Buffon, before mentioned, the authors of the British Encyclopædia, say that “By many experiments, particularly described in that essay, it appears that the tree should not be felled till the third year after it has been stripped of the bark; that it is then perfectly dry, and the sap [sap wood] becomes almost as strong as the rest of the timber, and stronger than the heart of any other oak tree which has not been so stripped; and the whole of the timber stronger and heavier,* and harder; from which he thinks it fair to conclude, that it is also more durable.” And they

* It is harder when of the same bulk with common timber, its fibres must be closer together, be they more or less previous to moisture, and consequently more durable.

add, that the navy board, in answer to the enquiries of the commissioners of the land revenue in May, 1791, informed them that they had then standing some trees stripped of their bark two years before, in order to try the experiment of building one half of a sloop of war with the timber, and the other half with timber felled and stripped in the common way.”—“We are sorry that we are not able to inform our readers of the result of the experiment.”

Commodore Porter and his colleagues of the American Navy Board, may have it in their power to make, and carry into complete effect the same experiment. So may farmers possessed of timber trees. To render the experiment more fair and conclusive, trees as nearly as possible of the same size, and growing in the same soil, should be selected. Growing in the vicinity of each other, the equality of size will be an indication of an equality of age,—a point probably, of material importance.

These experiments I hope will be made extensively by farmers, in preparing their trees for fencing, and for carts and other implements much exposed (often unnecessarily) to all changes of the weather. For however plausible theories may appear, careful experiments alone can determine their correctness.—Experiment by farmers may very easily be made, in their fences; by having some panels (or lengths of rails) of timber prepared in one way and then a like number of timber prepared in the other. At the same time too, they can try an experiment to ascertain whether, in post and rail fences, the rails, with their heart edges downwards, will last longer (as the commodore supposes) than with those edges upwards, in the mode universally practised. He suggests that the concentric rings (the annual growths) in trees split into rails, and these placed in fences with their edges upwards, form so many cups or hollows, into which the rains and dews falling on the rails enter; and having no other way to escape, soak through the rings to the sap wood and bark on the under side, and thereby hasten the rotting of the heart wood above. I much doubt the correctness of this theory. Rails placed with their heart edges upwards, have very steep roofs, by which water speedily runs off. Their heart-wood soon seasons, and its surface becomes close, without visible cracks. But place the broad bark side upwards, the falling water rests longer upon it, and enters the sap wood, often an inch or more in thickness, and as soon as this shall become rotten, it will be a sponge to receive and hold water, to soak into and gradually rot the heart-wood below. Such is my view of this subject; but let experiments be made. For the purposes of the navy, or other shipbuilding, experiments may also be easily made; though not so satisfactorily as by constructing a vessel with the two sorts of timber as designed by the English Navy Board. An equal number of pieces of timber felled in the two different ways, may be dressed to the same sizes, and equally exposed to the weather in all its changes; and to expedite the result, they may be often immersed in water, so as to be almost daily wet and dry.

Hickory (in New England generally called Walnut) grows in many parts of our country. It is a tough and hard wood; but when exposed to the weather, soon decays; yet may, it seems be advantageously used in salt waters infested

with worms. Eighteen or twenty years ago, passing by a saw mill placed on tide water, I observed some hickory planks. I asked the Sawyer for what use they were intended. He answered, for the sluice ways or other water works, of tide mills; because, not liable, like oak, to be eaten by the worms. Passing a few days ago by some tide mills on the same stream, I mentioned the fact just stated to one of the proprietors. They continue to use hickory for the same purpose, because, said he, "the worms can't touch it." Any person inclined to make trials of this wood for such purposes may previously ascertain the fact, by sinking two pieces, one of oak and the other of hickory, in waters where worms are known to abound; and after a few months taking them up again.

TIMOTHY PICKERING.

Salem, Sept. 10, 1821.

From the New England Palladium.

DOMESTIC COFFEE.

I have learned, to my great concern, that the good people of Boston, and some parts of its vicinity, have lately acquired the practice of sing what they call "Domestic Coffee," by way of economy; and after making some inquiry concerning it, I find some of it to be a compound of half Rye and half imported Coffee round together. When I made this discovery, was at no great loss to account for the vast number of persons, who, of late, have suffered much from weakness in their limbs, and debilitated systems. Rye is peculiarly calculated to reduce that effect, in whatever way it may be used—more especially when it has been roasted and ground with coffee where every particle of fluid is extracted and absorbed in the coffee. Let Rye be ground into meal, and bread made of the meal be eaten without sifting, and it will have an effect similar to opium. Let rye bran be given to pigs, and it will make them lie down and swell with weakness; but a person may eat of the fine meal without witnessing any ill effects. The reason of this is, that the debilitating fluid is attached to the hull of the grain.

Let a horse eat as much Rye as he will, and will destroy him, by taking away first the strength of his limbs, and then that of his whole body.

A Friend to Health.

HYDROPHOBIA.

The Baltimore Chronicle gives an account of a distressing case of the hydrophobia which occurred in that city last week. Mr. Samuel Dunham, who was bitten by a mad dog nine weeks since, died on the 20th ult. in horrid agonies. He was convulsed in every joint; rothed at the mouth; and it required the strength of two men to hold him in his bed—withstanding he was bitten so long ago, it was only on Thursday last that he exhibited decided symptoms of the hydrophobia, and before Friday night he was a cold corpse. The deceased, amidst all his spasms and agonies, retained the clear possession of his reason to the last. He has left a wife and several children.

A Cucumber grew this season, in the garden of Mr. Lovell Eames, in Framingham, measuring 18 inches in length and 7 inches in circumference.—*Spectator*.

To the Editor of the American Farmer.

FOUNDER IN HORSES.

Paris, Bourbon Co. Ky.

Dear Sir,

After a journey devoid of interest, owing to the lateness of the season, I have arrived in Kentucky, and being desirous of communicating a cure for "Foundering," recently known; I make one effort to conduce to the value of your present work, the American Farmer.

One of the writers in your "Farmer" calls foundering, "chills and founder," and compares it to inflammatory rheumatism; I apprehend he does not understand the disease in all its stages;—it evidently proceeds from *surfeit*. A horse rode until heated and fatigued, and fed too plentifully while warm and hungry—and swallowing his food too greedily, that he may lie down and rest his wearied limbs;—and the stable being wet or damp, and the horse in a copious sweat, are reasons the best that can be given, for the formation of the disease.

Instead of rising up refreshed, the poor animal is stiff and useless. If he had got leave to cool perfectly, and been fed sparingly, he would have escaped *this* sore complaint.

The cure is a lump of alum the size of a walnut, reduced to powder and dissolved in warm water; the horse must be drenched with this liquid, which in a short time will throw him into profuse perspiration, and he will be able to pursue his journey the next day, and if not badly foundered, in a few hours.

You will keep it out of sight that this communication comes from a woman, as I wish to escape the

"World's dread laugh, which scarce

"The firm philosopher can scorn."

Yet it is a fact that I always prized fine horses, and endeavored, by every means in my power, to alleviate their pain.

Pray do not put yourself to the expense of sending seed you have to purchase. I hope you received the last seed I sent you enclosed in a letter from Missouri, particularly the "Prairie Sensitive Plant" seed.

P.S.—The valuable remedy for the founder was communicated by Col. E. Chambers, who experienced its good effect on his own horses, and others.

The authoress of the above is amongst our most valued and useful correspondents, worth a million of indolent men, who neither write nor think any thing useful to society—and yet who call themselves the Lords of the creation—acting the whole part of sluggish drones—*fruges consumere nati*.

From the New York Mechanic's Gazette.

AMERICAN SILK GOODS.

Mr. Jas. Read has done us the favor to call at our office to show a piece of elegant blue striped silk, manufactured by him for a suit of chair and sofa coverings, for the Hon. Mr. Crawford, secretary of the treasury. It is made of Italian and American silk, the latter of which is made at Mansfield, Conn. where we understand that the silk worm is cultivated to a considerable extent. Mr. Read's vest patterns, and watch chains have heretofore received public notice; they are said to be equal to the best English, and can be afforded on equal terms, but the specimen of silk above referred to (about forty

yards) far surpasses any thing we expected to see of domestic manufacture for many years to come, and is a flattering specimen of taste and ingenuity, which cannot fail to meet with encouragement. We hope that Mr. Read will be favored with similar orders from our wealthy citizens, who can have their taste gratified with any color and pattern they may select.

From the Boston Patriot.

DOMESTIC WINE.

We are informed that an enterprising agriculturist in Newton, through whose attention and application to the raising and cultivating of fruit trees many of the farms and gardens in the vicinity of our city have been furnished with the best of fruit, has this season manufactured seven hundred gallons of Currant Wine. This, it will be recollected, is manufactured by one individual. Should the same spirit of enterprise prompt one individual in each town in the Commonwealth to produce an equal quantity of this pleasant beverage, we should soon need no importations of common wines, but might rely wholly upon the product of our own gardens, for a supply for domestic consumption.

On Monday, says the Newark, N. J. Centinel, we were presented by Mr. Leonard Richards, with a Green Gage, (a species of plum) of an extraordinary size. It measured six inches in circumference, and weighed 2 1-2 ounces.

From the Hampshire Gazette.

Tobacco.—Experiments are making in Pennsylvania with the Cuba Tobacco, so celebrated for its fine flavor; it promises well and several loads have been cut and housed; some of the leaves are 25 inches long, and 16 broad. This kind of tobacco is said to be worth \$80 per hundred in the Havana.

Cattle.—It is stated in a Hamburg paper of April last that two oxen raised in the county of Holstein Ditmarsen, Germany, weighed, after being killed, as follows. Largest ox 4452 English pounds, the second 4034 pounds.

Leeches.—It is stated in a London paper that a gentleman after applying eight leeches to an inflammation, deliberately cut off their tails; notwithstanding which they continued to adhere as before, whilst the blood poured thro' them in an uninterrupted stream. The editor observes that these leeches resemble some state leeches, called ministers of state.

The following experiments were made with a thermometer, at the Navy Yard, in Norfolk, Va. on the 2d inst.

At half past 11 the temperature in a house was 83 degrees. The thermometer was then suspended in the open air, sheltered from the rays of the sun by a *brown linen* umbrella, when it rose in a few minutes to 93. It was next placed under a *silk* umbrella, and in the same period rose to 97. Exposed to the sun it stood at 112.

A very general alarm prevails respecting the danger from canine madness. Measures to afford greater security to the Citizens have been adopted in most Cities, and are conceived by many, to be greatly needed in this.

Palladium.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.

POTATOES

Should be dug and housed as soon as they are ripe, and before the vines are entirely dead. In this state they generally adhere to and may be pulled out of ground with them; but if they remain in the ground until the vines are quite dead they separate from the vines, and the expense of digging them will be greatly increased. A sort of an hoe, with prongs or claws like a fork, and fixed at the end of an handle like a common hoe, and which may be had at the Agricultural Establishment of Lincoln Fearing & Co. No. 20, Merchant's Row, near the old Market, Boston, is said to be very useful, and much superior to the common hoe for digging potatoes, as well as for various other purposes.

It is said that a very good kind of fodder for horned cattle may be made of potatoe tops, by spreading and drying them on grass ground in the vicinity of the potatoe field. We are told that in the Southern states, they reap about two thirds the length of the potatoe tops, and dry them on mowing land in the usual way of hay-making. Several tons may thus, sometimes, be collected from an acre, and no damage be done to the potatoes, if the tops are not gathered till the potatoes are ripe.

The following method of preserving potatoes was communicated by Mr. Millington (England) to the Society for Bettering the Condition of the Poor:—

I caused, (says this gentleman) three pounds and a half of potatoes to be peeled and rasped; then put in a coarse cloth, between two boards, and pressed them into a dry cake, hardly so thick as a thin cheese. They were then placed on a shelf to dry. There was about a quart of juice expressed from the potatoes. To this was added about a like quantity of water, and in about an hour it deposited more than sixty grains of white starch or flour, fit to make pastry. A cake of this was prepared and sent to the Society. In bulk it occupied only a sixth of the compass of the potatoes; in weight it had lost about two-thirds by the process; but the cake, when dressed with steam or otherwise, will produce nearly the same quantity of food as three pounds and a half of potatoes, properly dressed for the table would do. Some potatoes, quite frozen, have been prepared this way, and the cake was perfectly sweet; whereas some of the same parcel that were left, and not pressed, were spoiled in a few days.

PARING AND BURNING.

A new method of "burning without fire" has been lately discovered. This consists in substituting quick-lime for fire. The lime in its most caustic state, fresh from the kiln, is laid upon the vegetable surface to be consumed; and before it is weakened by exposure to the air, a quantity of water just sufficient to put it in powerful action, is applied. This process unites the advantages of burning and liming, and is probably the readiest and cheapest mode of fertilizing soils, which superabound with vegetable matter, and for which lime would prove a suitable manure.

French mode of making Brandy-Peaches.

Preserved fruit is generally cloying, and often times unwholesome to the stomach, because

of its *unmixed sweetness*, arising from the manner in which they are usually prepared.

The most grateful preparation of the peach we have ever seen, is that which is accomplished by the following process:

Scald them in hot water, then dip them in hot strong lie, rub them with a cloth and throw them into cold water; make a syrup of 3-4 of a pound of sugar to one pound of fruit, and when cold put in an equal quantity of brandy.

Amer. Farmer.

BUTTER.

The following is given as an improved method of preventing the bitter taste which butter has from cattle feeding on turnips, cabbages, leaves of trees, &c. Boil two ounces of salt petre in a quart of water, and put two or more spoonfuls, according to the quantity of milk, into a pail before milking; if this is done constantly, it will prevent the taste of turnips, but it will not be effected if even once neglected. This has been proved by twenty years' experience, and if it does not succeed the farmers may rest assured that the fault arises from the neglect of their dairy maid.—*ibid.*

"To generate the best kind of seeds, the most healthy plants must be chosen, and those which are most early in respect to the season; these should be so insulated, as to have no weak plants of the same species, or even genus, in their vicinity, lest the fecundating dust of weaker plants should be blown by the winds upon the stigmata of the stronger, and thus produce a less vigorous progeny.

"When new varieties are required, the male dust of one good variety, as of the nonpareil apple, should be shed upon the stigmas of another good variety, as of the golden-pippin; and it is probable that some new excellent variety might be thus generated."

Darwin's Phytologia.

Working Oxen.—When oxen refuse to work equally well on either side, or when they pull off against each other, yoke them on the side you wish them to work, and turn them out to feed in that way; they soon become accustomed to it, and work afterwards on either side alike.—*Amer. Farmer.*

Dr. Lettsom observes that in general, pies are more advantageous than roasting or boiling. This he illustrates. Of mutton, 64 ounces in a *pye*, made with 24 ounces of wheat flour, and eaten with 3 1-4 ounces of bread, in all 96 1-4 ounces, dined eight persons fully; whilst 60 oz. of mutton *roasted*, and eaten with 33 ounces of bread, in all 93 ounces, dined only five of the same persons.

Potatoe Pudding.

12 oz. of potatoes, boiled, skinned and mashed.
1 do. suet,
1 do. milk, that is, two spoonfuls,
1 do. cheese,

Mix all together with boiling water to a due consistence. Bake it. Instead of cheese, there may be an ounce of red herring pounded fine in a mortar.—*Lettsom.*

Potatoe Bread, in England.

A skillet of potatoes, with cold water is hung at some distance over the fire, that the water may not boil, till the potatoes become soft.—Then skin, mash, and mix them with their weight of wheat flour, and also with the yeast,

salt and warm water wanted. Knead all together. Lay the mass a little before a fire to rise; then bake in a very hot oven. Flour of rice or barley may be used instead of that from wheat.

Another mode is given by the *Board of Agriculture*. It directs, to select the most mealy sort, and boil and skin them. Break and strain 12 lbs. of potatoes through a very coarse hair sieve, or a very fine one of wire, so as to reduce the pulp as near as possible to a flour. This quantity makes nine loaves of 5 lbs. each, in dough; or when baked about two hours, 42 lbs. of excellent bread.

Dr. Fothergill says, if potatoe bread is cut before it is a day old, it will not appear enough baked; because of the potatoe moisture. He adds, never slice potatoes with a knife, raw or boiled, but break and mash with the hand or a spoon, otherwise they will not be soft.

Doctor Lettsom next proceeds to give the best soups; according to Mr. Justice Colquhoun.

1. Potatoe Soup.—Colquhoun.

Stew 5 pounds coarsest parts of beef or mutton, in 10 quarts of water till *half done*. Add quantity of potatoes skinned, and some onions pepper and salt.—Stir frequently and boil enough. Bones of beef added would increase the soup in richness or quantity.

	MILLS
Estimate in mills.	
5 lbs. coarse beef at 60 mills	300
Bones, to enrich it	50
Potatoes 24 lbs. or 1-3 bushel	20
Onions, a bunch	20
Pepper and Salt	60

49.

It gives 10 quarts of soup, meat and potatoes and dines 10 men at nearly 5 cents. A *red herring* is said to be a good substitute for onions pepper and salt; but red pepper may be added.

II. Barley Broth.—Colquhoun.

It admits of a mixture of almost every kind of garden vegetable, and is never out of season. Onions or leeks and parsley are always a pair of the ingredients; besides which, cabbage or greens, turnips, carrots, and peas may be added. A teacup of barley suffices for a large family.—*Pearl barley* is dearer, yet not so good as the *common husked* or *Scotch dressed barley*. Water 4 quarts, beef 4 pounds, with bones, barley 4 ounces, [Count Rumford says *barley meal* is better than whole barley for thickening broth, an making it more nourishing.] Stew all together two hours. Then add the herbs cut small, an salt. The whole then *boils* till tender. Skir off the fat or not, as you like it. Onions or leek must not be omitted.

III. A plain good food, with very little meat, as wholesome as can be obtained from wheat or barley.—Colquhoun.

Cut half a pound of beef, mutton or pork, into small pieces; add half a pint of peas, 3 sliced turnips, and 3 potatoes cut very small; an onion or two, or leeks.—Put to them 7 pints of water and boil the whole gently, over a slow fire for 2 1-2 hours. Thicken with a quarter pound of ground rice, and one-eighth pound of oat meal (or 1-4 lb. pound of oat meal or barley meal without rice.) Boil 1-4 hour after the thickening is put in, stirring it all the time. The season with salt and pepper, or ground ginger. As only a pint will be lost in boiling, it is a meal for 4 persons, and will cost 2 cents each person.

IV. Cut into very small bits, 2 pounds of beef, mutton, or pork, out of the tub, or hung beet

reshened in water; and put them in a pot with ix quarts water. Boil *stew* near three hours, or rather *stew* till tender. Add 1-4 lb. carrots or parsnips, and 1-2 lb. turnips, all sliced small. Sometimes instead of them a few potatoes sliced; also add some greens, cabbage, cellery, spinach, barley, and two ounces onions or leeks. Thicken with a pint of oat meal, (or a quart to make it very thick.) Boil it well together, and season with pepper or ground ginger and salt. It will serve a family of six for a day. Or it may be thickened with any kind of meal, or barley, peas, beans or rice.

V. Take 4 lbs. beef, onions 3-4 lb. turnips 2 lbs. rice 1 1-2 lbs. parsley, savory, thyme, of each a large handful, pepper and salt; water 17 quarts. Cut the beef into slices, and after boiling it some time, mince it small. The turnips and onions infused, and sweet herbs may be minced before they go to the pot. Boil the whole gently together about three hours on a slow fire. Scarcely two quarts will be wasted in boiling. The rest will serve 18 persons for one meal. Cost 2 cents each.

Where fuel is scarce, the materials in the three above receipts may be stewed in a pot, all night, in an oven, and will next day require but a quarter hour boiling.

VI. Bake in an earthen pot, a shank of beef, a six quarts of water, with a pint of peas, a leek, and four or five turnips sliced

COW.

The principal distinguishing marks of a good Cow are said to be these: wide horns, a thin head and neck, dew lap large, full breast, broad back, large deep belly; the udder capacious, and not too fleshy; the milch veins prominent, and the bag tending far behind; teats long and large; buttocks broad and fleshy; tail long, shaggy and small in proportion to the size of the carcase, and the joints short. To these outward marks may be added a gentle disposition, a temper free from any vicious tricks, and perfectly manageable on every occasion. On the other hand, a cow with a thick head and short neck, prominent back bone, slender chest, belly tucked up, small udder or a fleshy bag, short teats, and thin buttocks is to be avoided, as totally unfit for the purposes either of the dairy, the suckler or the grazer.

The milch cow is generally in her prime at five years old, and will continue in a good milking state till ten years of age or upwards. Cows should be milked regularly, morning and evening, and always as nearly at the same hours as may be. Some have recommended milking them three times a day, at five, one and eight; and it is said if they are full fed they will give half as much again milk if milked thrice as if only twice a day. Those farmers who would make the most of their cows should provide a bull to run in the herd.

ON STALL FEEDING.

"Stall feeding of bullocks with potatoes, given in different states of preparation, has been for some time extensively practised in Sussex, and is much approved of by many. They there find that a beast of from one hundred and forty to one hundred and sixty stone* weight eats from one to two bushels of the roots in the course of the day, but consumes but little hay, or not much more than ten or twelve pounds in

that space of time." "And a careful experimenter, who was largely in the practice of fattening oxen with them, it is said, gave them up—from the conviction that with every advantage of breed, attention, warmth, and cleanliness in regard to the animals, they would not pay more than four pence the bushel."

"Further, the Swedish turnip when it is cultivated in a proper manner, is a most valuable root, when used with this intention."—"In some trials which we have lately attended to, it was found to have the advantage, nearly in the proportion of one fourth; and in other experiments, it is said to have gone still farther in this use."

"And the proportion in which they are consumed by the fattening stock, has been found to be something more than a third of the weight of the cattle by some; but by others, about a third in the day, as stated in the Gentleman Farmer. However, in other experiments carefully made, an ox of from seventy to eighty stone has been ascertained to eat something less than three hundred weight in the course of a day, besides chaff and hay; and small cows of about thirty stone, one hundred weight and three quarters in the same time. And in the Rev. Mr. Close's trials it was found, that when consumed in stalls and sheds, an acre of good turnips, will completely winter fat an ox of fifty score."

"When this root is given in the stall, from its very succulent nature, it becomes necessary to employ as much dry food as possible during the use of it, in order to the expeditious fattening of the cattle by such means."

Recs' Cyclopaedia.

Cud lost by an ox or cow, —REMEDY FOR.

Mix together an equal quantity of sour leaven and common salt, then add a piece of loam or brick clay, equal in weight to the whole: break and mix all these well together, and then add as much urine as will serve to beat it up into a paste. Make this into two or three balls as big as the creature can swallow, force one of these down his throat every three days and it is said it will effect a cure.

Receipt for American Tokay.

A barrel of good new cider from the press. Let it ferment, carefully brushing off the froth, as it comes out of the bung-hole. When the fermentation ceases, draw it off and add as much honey as will give it strength enough to bear an egg; return it to the barrel which should be washed clean. It will now undergo a second fermentation, which must be treated as the first, and when that ceases, add half a gill of French or peach brandy, for every gallon. Bung it tight and so let it remain until the March following, when in a calm, clear and dry day, it should be bottled.—*Amer. Farmer.*

MASSACHUSETTS AGRICULTURAL REPOSITORY AND JOURNAL, FOR JUNE.

(Continued from p. 11.)

The next article to those which we have before remarked upon, has the signature, "*A Roxbury Farmer*," and is entitled "A comparison of the present with some past seasons." This article we have given at large in the 1st No. p. 2. It appears to be one of a series of similar notices which have for a number of years been published by the same author. Such a Kalendar, regularly kept from year to year, cannot fail of proving of great importance, "if cultivators, instead of consulting the almanack will attend to the indications of nature."

Dr. Bacon, in his *Farmer's Dictionary*, observes, "That great naturalist Linnaeus, did not approve of farmers confining themselves to certain set days, or weeks, for committing their seeds to the earth. The seasons are much forwarder in some years than in others; therefore, he, who thus governs himself, will assuredly sow his annual seeds sometimes too early and sometimes too late."

"That a better practice might be introduced, he recommended it to his countrymen to take notice at what time the trees unfolded their leaves, &c."

"In order to reduce to practice so ingenious a hint, an account should be made out of the first leafing, and I may add the blossoming of a variety of trees and shrubs. I suppose trees and shrubs to be most suitable for this purpose, as they are more deeply rooted, and therefore more steady and uniform in their appearances, than any plants which are perennial only in their roots. They are especially much more so than annuals."

"It is certain that such an account taken in one place will not answer alike for every part of the country; because the vegetation in every part is not equally forward. Therefore, I would earnestly recommend, that in each degree of latitude, throughout New England at least, some attentive naturalist would make a list of a considerable number of trees and shrubs, which are near at hand; carefully watch their appearances, and minute the times of the first opening of their leaves, and also of their blossoming. By comparing the accounts, the absurdity will immediately appear, of sowing the same kinds of seeds at the same time of the month or year, in the 42d, 43d, 44th and 45th degrees of latitude."

"When these accounts are obtained, let trials be made by sowing a certain kind of seed before, at, and after the foliation, or the flowering of some particular plant, and the produce compared. Let accurate experiments of this kind be yearly repeated, with all the most useful spring plants; by this, in a few years, complete kalendars may be obtained for every degree of latitude in this country. The consequence will be that the farmer will be able to read the true times of sowing by casting his eye upon the trees and shrubs that are about him. We have already such a rule as this with respect to Indian corn; but it perhaps ought to undergo a further examination."

"But such rules, after all that can be done, ought not to govern us invariably. The right times of seedling admit of some latitude, on account of the degree of dryness of the soil, and of its exposure to the solar warmth. Land should have the right degree of moisture when seeds are sown on it; and a southern exposure will afford an earlier vegetation than a northern."

The statements and views of *A Roxbury Farmer*, are ably corroborated by the writer of the next article, who uses the signature "INDICATOR." This gentleman remarks that

"If each farmer or gardener will make his own observations within his own grounds, and always upon the same plants, while in health, and under the same degree of cultivation; and make his notes with care when the state of the blossom is at the same stage of forwardness, there can be no doubt of its correctness. Let him take his own asparagus bed as an index of the warmth of the ground in the early part of May, and he can judge with great correctness, provided the asparagus bed be always forked and dressed on the same day, or nearly, in the month of April, and with the same quantity and quality of manure: for on this plant the warmth of the soil acts immediately on the root alone, and therefore there can be no better guide for

* Meaning probably eight pounds to the stone.

ascertaining the temperature of the ground at that season. If we can plant corn and squash seed the middle of May when the asparagus is in a state to be cut the 7th of that month, why not plant those seeds the 7th when the asparagus is fit to cut the first of May? A peach tree, cherry tree, or a plum tree in good health, is also a fair indication of the temperature of the earth, as is the apple and pear tree, if always kept in a good state, or in a cultivated or ploughed piece of ground; but in the orchard, where the grass is allowed to check the circulation, three years out of five, trees are not so correct an index as the asparagus bed, or as they themselves are when growing in a garden or ploughed field where the ground is always open, so that the rays of the sun and the warmth of the atmosphere enter with less obstruction.

I have said that the *same* plant should always be taken as the standing index, because peaches, for instance, of different sorts or varieties, and cherries of different sorts, as well as pears and other fruits, open their buds and blossom sooner or later according to the respective habits of each individual or variety; so that a person who should take one year an early peach, and the next the late peach as his index, might find himself very far from correct.

With respect to the rains which prevail in the month of May, by which seeds are rotted in the ground, I apprehend that if the ground be warm enough to excite the germ of the seed early in May, it will as soon be out of danger from rot, as if it be planted the middle of May; for the rains prevail as much towards the last as the first of the month. And as respects the late frosts which are dreaded so much by many people when the spring is early open, I confess, that so far as my own observation goes, I should fear it less when the spring is forward than when it is tardy. I don't mean to say that premature heat, which we sometimes have, is not like to be followed by frosts in May; but when the spring continues to put forth new evidence daily of its settled state in a regular and natural manner, so as to bring forward vegetation early, and with unusual vigor in May, I think there is much less danger of late frosts than when the cold blasts from the Canada borders are constantly interrupting its progress—because in one instance the earth is gradually warmed, and creates within its influence a warm atmosphere that prevents frost from taking place; whereas in the other case the earth continues cold, and the temperature of the atmosphere near its surface is less capable of resisting the night chilling dews which fall upon the young plants that are putting forth. I believe that if recourse be had to the state of the weather for any ten years together from the 25th March to the 5th May, it will be found that late in the season frosts have occurred much more frequently when the average temperature of the spring months has been below rather than when it has been above any given point.

We think, with the above quoted writers that it would be a matter of but little difficulty for every farmer to make him out a *Veritable Almanack*, from the productions of his own soil; and thus turn, as it were, the *Book of Nature* into a *Perpetual Calendar*. This might be done without any reference to the artificial 12, or of days, as set down in common almanacks,

and, we think, would prove not only simple, but correct and useful. For example:

The Gooseberry buds begin to swell.	Sow early peas.
Willow buds do, do.	Sow flax, early Spring wheat and spring rye.
Lilac do, do, do.	Plant potatoes, early use.
Asparagus fit for table.	Plant a potatoe patch, also some pumpkins near your hog sty.
Currants put forth leaves.	Plant garden beans.
Apple trees blossom.	Sow carrots, beets, &c.
White oak leaves as big as a mouse's ear.	Plant Indian corn.*

We give the above as something like the form which might be adopted for the purpose of enabling the young and inexperienced agriculturist to adopt some general rules for seeding his grounds. The substance of the Calendar must be established by actual observation, and be the result of good sense operating upon experience.

An advantage, which perhaps has not been adverted to, may be anticipated from recording annually articles like that of *A Roxbury Farmer*, in which the times of the annual budding and flowering of plants are noted. The practice will afford data for ascertaining with considerable precision the effects of cultivation as regards climate. Some philosophers tell us that by depriving the earth of its forests, and opening its surface to the more direct influence of the sun's rays, the springs come on earlier upon an average, and the mean temperature of the climate is increased. Others deny these positions, and say that the mean temperature of the climate can neither be increased nor diminished by any changes on the earth's surface, as the quantity of caloric emanating from the sun will be the same in corresponding latitudes, whether such surface be comparatively rough or smooth; and that when we expose the earth to the more direct impulse of the solar rays, we likewise deprive it of a mantle which covered it in some degree from the frigid influence of those northern blasts which so often bid "winter chill the lap of May."

(TO BE CONTINUED.)

* This we believe is the Indian maxim alluded to by Dr. Deane as above.

NEW ENGLAND FARMER.

BOSTON:—SATURDAY, AUGUST 17, 1822.

The Editor would be happy to make his best acknowledgments acceptable to certain conductors of newspapers and others whose talents and stations give them influence, for the favorable notices which they have taken of this establishment. The indications of good will, and expressions of approbation, with which he has been honored, having been received from gentlemen well qualified to appreciate the value of literary and scientific efforts, cannot fail to add stimulus to industry, and elicit every possible effort to realize the favorable anticipations which appear to be entertained by men, the recognition of whose good opinion is an object of high and laudable ambition.

Among those to whom we are under great obligations for announcing our paper in terms well adapted to introduce it to general patronage, we shall hold in great remembrance the Editor of the *Manufacturers and Farmers' Journal*, a valuable paper, printed at Providence, R. I. We hope we shall not be accused of egotism in giving the following extract from an editorial article which appeared in that paper of the 12th inst. since it relates principally to our *object*, which it cannot be supposed to have escaped notice to the laudable,

and gives, among other topics, a lucid exposition of the benefits which cultivators may hope to receive from the *New England Farmer*, by making it a channel for communicating to the public their own discoveries and improvements.

"There are many good reasons for the establishment, in the northern section of our country, of a paper mainly devoted to the interests of Agriculture. The most prominent is, the great difference between the climates of the Southern and Northern States. This difference, requiring the cultivation, in one section, of crops which cannot be cultivated with advantage in others, produces, of necessity, different systems of farming. Every enlightened cultivator, wherever he may live, has a system of his own, adapted to the peculiar situation of his land, as well as to the general character of the climate under which it lies; which system is the result of experience. A number of such men stipulate, for their mutual benefit, that each shall communicate to the whole, the result of his own experience, and to make a paper, like the one under consideration, the vehicle of communication. Now the utility of such an agreement depends on the limits which are prescribed to it, and the fidelity with which it is executed. It is plain, that those only who cultivate the same crops can be mutually serviceable to each other. The planters of Georgia and Carolina, whose crops consist principally of cotton, rice and sugar, cannot communicate much useful information to the farmers of the northern and middle states, who cultivate grain and keep large stocks of animals, in a climate where the season is from two weeks to two months shorter than it is with them—nor can they learn of the latter any thing which may be generally useful in their planting. The difference of soil and climate, even between the northern and middle states, is so considerable, as to require, in the one, a system of cultivation, widely different from that which is practised in the other. In every section of our country, therefore, distinguishable from the others by peculiarities of climate and soil, and following a system of husbandry materially different from the systems in practice elsewhere, there ought to be established a paper which should be made a common medium, through which every experienced farmer may convey to his brethren the result of his own experience. This paper should be supported and made useful, by a punctual payment of the subscription money, and by a constant supply of original matter."

Since the above was in type we have been indebted to the kindness of Mr. SKINNER, of Baltimore, not only for the common civility of a proffered exchange of papers, but for a complete file of the current numbers of the 4th vol. of that excellent work, the *American Farmer*, together with an elaborate index of the 3d volume, containing three printed sheets. To these highly valued favors is added a friendly letter, in which is evinced a disposition to "strengthen our hands and encourage our hearts," in the duties of our present employment. We are happy to be assured of a fact, (which indeed we had anticipated from Mr. Skinner's reputation for liberality and regard for the interests of the community,) that the able Editor of the *American Farmer*, a publication, which has, not only given a highly beneficial impulse to American agriculture, but whose establishment may be considered as the commencement of a new and brilliant era in its annals, is willing to regard us as a coadjutor, worthy to second his efforts in "extending the knowledge of all discoveries in the science, and all improvements in the practice of Agriculture and Domestic Economy." Mr. Skinner's approbation cannot fail to be of essential advantage to us, and we would tender in return our tribute of gratitude, and proffer the best services in our power to render to him or his establishment.

COOKING FOOD FOR CATTLE.

Among the most useful improvements of modern husbandry may be numbered the practice of steaming or boiling food for domestic animals. Some account of the origin of this practice in Great Britain may be

found in the "Complete Grazier," an excellent English work of high authority, from which the following is extracted.

"Steamed food may be given to milch cows with great advantage. For this important fact in rural economy, we are indebted to the ingenious and persevering experiments of J. C. Curwen, Esq. M. P. whose attention to the comforts of his tenants, and judicious zeal for the improvements of agriculture are too well known to require any eulogy. In prosecution of a system which he had long practised of giving cooked food to animals, Mr. C. turned his attention to the cheap mode of supplying milch cows with it; and in a communication to the society for the encouragement of arts, &c. (which was honored with their lesser gold medal) he states his belief that he has at length been completely successful. He uses a steam boiler of 100 gallons contents,* on each side of which are fixed three boxes, containing 11 stones each of chaff, (the husks of wheat, rye, &c.) which, by being steamed gain more than one third of their original weight. The steam is conveyed by various stop cocks into the lower part of the boxes; and thus two or three boxes may be steamed at the same time; the quantity of fuel required is about 2 lbs. for each stone of chaff.

"In giving the steamed chaff to the cattle, 2 lbs. of oil cake are mixed with one stone of chaff; and the milch cows are fed with it morning and evening, having an allowance of one stone at each time. On being taken from the steamer the food is put into wooden boxes, which are mounted on wheels to be drawn to the place where it is intended to be used; and the chaff requires to stand some time before it is fit for use.

"The average of milk on a stock of thirty-six milch cows, was nearly 13 wine quarts, for 320 days. The cows were never suffered to be turned out; and to prevent their being lame, their hoofs were properly pared, and they stood with their fore feet on clay. One great advantage attending this method was, that most if not all the milch cows were in such a condition that, with a few weeks feeding after they were dry, they became fit for the snaffles, with very little loss from the first cost. As a substitute for chaff and oil cake, Mr. C. recommends cut hay; which, when steamed, would make a much superior food, and he entertains no doubt would greatly augment the milk, as well as benefit the health of the animals. Mr. Curwen gives cooked food from October to June, nearly eight months out of twelve, and his plan of treatment has been adopted by several farmers in different parts of the kingdom with great success."

The practice of cooking food for cattle is by no means a novelty in New England. A simple apparatus or that purpose has been for some time in use among farmers of our acquaintance. The following is a brief description of it. A kettle, holding twelve gallons or more, is set in a furnace of brick or stone, and over his a hog-head with one head taken out and the other closed full of holes. This is set so close that the steam of the kettle, when boiling, can only rise through the holes, and thence ascend among the articles to be boiled in the hog-head and pass off at the top. In this way a hog-head of potatoes will be nearly as soon boiled as a small part of them could be if placed in the kettle underneath.

As the kettle is so closed as to prevent any steam on passing off, but through the bottom of the hog-head, a pipe or tube is set in such a manner that with the aid of a funnel water may be poured into the kettle often as is necessary. After poured in, the tube is stopped with a plug for that purpose.†

*An engraving of it is given in the 30th volume of the Society's Transactions.

†14 lbs. a stone.

‡The "Complete Grazier" contains a drawing and description of this simple apparatus, which it calls a "steamer," and observes that it was introduced into England from America. It states that the top of the hog-head, which in America "is usually left open, may be advantageously be covered with a thick coarse cloth, which is much better, after the vessel is filled with the steamed roots, it is closely clayed all round, and the head

Grain of all kinds may be steamed boiled by this apparatus, to great advantage, for feeding or fattening cattle; but in that case, it is requisite to have the bottom of the hog-head covered with a cloth, to prevent the grain from running down through the holes.

Experiments have been made in Pennsylvania, by which it appears that Indian corn and potatoes will fatten swine one third faster when boiled or steamed than when given to them without any preparation.

An Address delivered to the Maryland Agricultural Society, by their President, Mr. Robert Smith, and published in the American Farmer, No. 11, Vol. 3, contains the following observations on this subject:

"Economy in the feeding of stock is an object of the highest importance, interesting alike to the public and to the individual. The great waste of hay, straw, corn fodder, chaff and other feed, apparent on every estate, under the prevailing practice of our country, has suggested to me the expediency of having at my dairy farm a steaming apparatus. This I have recently established on a plan so simple and so cheap, that any person in any part of our country may have a similar one, greater or smaller, according to the extent of his farm and the proposed number of his stock. It consists of an iron boiler and two wooden boxes. The boiler contains 100 gallons. One of the boxes is eight feet, the other five feet long; both three feet wide and three feet deep. The boiler is globular, and was made by screwing together the rims of two salt pans. There is also attached to it a hog-head for any extra cooking.

"The boiler is fixed in brick work, calculated to afford the greatest degree of heat, with the smallest waste of fuel. Without pretending to give directions as to the particular construction of such a furnace, I would merely remark, what the physiologists have told us, namely, that heat being produced by the combined operation of the fuel and of the air feeding the fire, that portion only of the air, which passes in contact with the burning fuel, contributes to the production of heat, and that, therefore if the fire place should be larger than the heap of burning fuel, a certain portion of air will insinuate itself without going through the fire, and of course, not being decomposed will contribute nothing to the heat.

"To the water in the boiler is given all the heat necessary to generate the required steam. The steam is conveyed into the boxes by copper pipes attached to the upper part of the boiler, and is introduced between the bottom of each box, and a false bottom, consisting of several sheets of copper perforated with holes. Into this chamber, four inches high, formed by the two bottoms, the steam is conveyed, and passing through the holes of the false bottom, diffuses itself throughout the whole contents of the box, and thus effectually cooks the great mass of food therein contained. When sufficiently boiled, the steam, by means of a common stop cock, is turned into the other box. At one end of each box, and near the bottom, is a spigot and faucet, by means of which are drawn off the condensed steam and liquid matter, which had oozed out of, and been extracted from the cooked materials. This decoction is of a deep chocolate color and highly flavored. It may be given to the calves, or it may be returned to and mixed with the steamed food. It, however, may not be amiss to remark, that when a liquid feed is proposed the false bottom is not used.

"In the corner of the steam house, next to the pump, there is a hog-head of water in which is inserted a leaden tube, the other end of which is immersed in the water of the boiler and nearly to the bottom of it. The admission of the requisite supply of water from this reservoir into the boiler is regulated by a stop cock. And the cold water being specifically heavier than the warm, will necessarily take its place at the bottom, whilst the hot water will remain at the top. This simple plan is preferred to the self-supplying valve, which is apt to get out of order. At the top of the boiler there is a safety valve for the escape of all redundant steam, the electric force of which would otherwise endanger the whole establishment."

(To be continued.)

rusten I down to confine the steam; and, if necessary, a short wood-plug may be inserted for the purpose of admitting air, and which may be removed at pleasure."

LATEST FROM EUROPE.

The ship Triton, Capt. Bussy, arrived at this port on the 12th inst. in 30 days from Liverpool, and brought London papers to the 9th and Liverpool papers to the 11th ult.

Turkey and Russia have of late made no striking movements, nor assumed new attitudes either of a hostile or pacific nature. The Turks, however, according to the latest advices, continued to exercise the most atrocious cruelties on the miserable Greeks—stretching their ferocity to the utmost limits of their power. In the mean time the great Potentates of Europe appear to be gazing quietly on these scenes of suffering, and scarcely exhibit a symptom of sympathy for the sufferers; thus giving fresh proof of the correctness of the assertion of the moral poet, who says, "there is no flesh in man's obdurate heart." "Pity 'tis" that they have no pity, and well would it be, if changing places with the sufferers, these heartless monarchs could "be what they behold," till the actual endurance of calamity should teach them to put a stop to its infliction.

Spain continues in a state of confusion, and "civil dudgeon" adds domestic calamity to foreign menaces. The king proreigned the Cortes on the 30th June, on which occasion he made a clever and gracious speech, according with the spirit of the constitution. This, however, did not prevent tumults from taking place in Madrid. Some shouted for an absolute, some for a constitutional king, and others evinced a disposition to submit to no king. In the mean time France threatens the Spanish frontiers with about 60,000 men in arms, ready to take advantage of those domestic disturbances.

The distresses in Ireland continue undiminished, and it is said the funds of charity are exhausted. In London it has been proposed that every family should go without a dinner one day, and contribute the saving to the relief of the Irish sufferers. "War," says one of the Irish papers, "with all its horrors, is mercy, is paradise, to the condition of Clare, Kerry, Cork, Galway, Mayo and Sligo."

The Yellow Fever has made its appearance in New York, and several persons have fallen victims to that dreadful disorder.

MARRIAGES.

In Utica, N. Y. Mr. Franklin Sherrill, of Utica, to Miss Mary Ann Edwards, daughter of Thomas Edwards, Esq. of this city.

In this city, Mr. John W. Gammage, to Miss Hannah Sawyer.—Mr. Joseph R. Tatt, to Mrs. Mary Manning.

DEATHS.

In South Boston, Mr. Joseph Hill, of N. Hampshire, supposed to have fallen overboard in a fit.

In this city, Mrs. Fear Scudder, wife of Mr. Charles Scudder, 33.—Mr. James Furness, 32.—Mrs. Lucy Watts, widow of Mr. Prince W. 61.—Widow Jane Hammond, 73.—Mr. Caleb Clark, 2.—Sydney B. Williams, son of Robert W. Esq. 14.—Mrs. Lydia Maria Greole, wife of Mr. Samuel G. 31.—Mr. John Sullivan, 42.—Drowned, Master Samuel S. son of Mr. Samuel Norwood, 13.

GREAT ADDITIONS TO THE NEW ENGLAND MUSEUM.

76. COURT STREET.

THE Proprietors of this extensive establishment have the pleasure to announce to their patrons and the public, that, besides their usual continual additions of curiosities from all parts of the World, they have just added another entire Museum, making now one

Grand Consolidation, of 4 Museums united in one.

The late additions alone are superior in extent and variety, to any other Museum in this city.

Admittance 25 cents only.

August 10

From the New Monthly Magazine, for June.

AIR, "FLY NOT YET."

When eastern skies are tinged with red,
And fairest morn with hasty tread
Up-springs to ope Heaven's golden gate,
And chase the ling'ring stars that wait

To spy the blushing dawn;
While rays from Phœbus' glowing car
Gleam brightly on your casement's bar,
And pour a flood of glorious light
To shame the slothful sons of night,

Oh haste—oh haste
To snatch the fresh and fleeting hour
Ere noon has sipp'd each dewy flower
That decks the spangled lawn.

Oh shake off slumber's drowsy spell,
In morning's pleasant haunts to dwell;
And haste to join the feather'd throng,
To greet the dawn with choral song,
Or skylark's earlier lay:
With careless footsteps freely rove
O'er sunny plain, or leafy grove,
While new-mown hay its sweets bestowing,
Perfumes the air that's freshly blowing;

Oh haste—oh haste
To meet the bee on busy wing
O'er opening flowerets hovering,
And watch the squirrel's play.

To taste the gifts of earth and air,
That Phœbus' fiercer beam will scare,
On new-born buds of every hue
To trace the glittering drops of dew,

The timid hare to spy,
Who stealing forth, now hopes unseen,
To banquet on the humid green,
And oft, the while she fearless grazes,
Admires her leveret's frolic mazes,

Oh haste—oh haste—
Joys like these will never stay,
But melt like summer's mist away,
From days too piercing eye.

MISCELLANEOUS.

DOG-STAR AND DOG-DAYS.

The ancient Egyptians, in their observations on the stars, noticed that when a certain star of considerable magnitude first appeared above the horizon in the morning, just before dawn—the overflowing of the Nile immediately followed. Being warned by this precursor, they retired to the highlands to escape the inundation, carrying with them things necessary for their retreat. As this star performed for them the service of the house-dog, by warning them of approaching danger, they called it the dog-star, and supposing that this star was the cause of the extraordinary heat, which usually falls out in that season, they gave the name of dog-days to six or eight weeks of the hottest part of the summer. They ascribed an extraordinary influence to this star, paid it divine honors, and from its color formed prognostics, what the season would be. The Greeks and Romans also held the opinion that the dog-star was the cause of the sultry heat, usually felt about this time. Its influence was esteemed so great by the Romans, that they sacrificed a brown dog to it every year to appease its rage.

All these notions of the ancients, and all similar opinions that prevail at the present time, on this subject, are mere idle fancies. The dog-

star has no more influence in producing heat or sultriness, than any other star that decks the sky, and the days usually denominated dog-days, might with as much propriety be said to begin on the 20th or 15th of July, as on the 25th. The atmosphere suffers no greater change on the 21st and 25th of July, nor on the 5th and 6th of September, than it does on other days preceding and subsequent to those days. If the term dog-days has any appropriate signification it is because the word is intended to denote forty or fifty days of the most hot and sultry part of the year, but as these days vary almost every year in their commencement and termination, any notice in the almanack, or elsewhere, pretending to define the time when dog-days begin and end, is futile and of no more importance than the predictions concerning the weather.

PUTNAM'S ROCK.

The last number of the American Journal of Science, edited by Professor Silliman, of Yale College, contains the following "Extract of a letter from Professor Dana, of Dartmouth College, to the editor, dated Feb. 5th, 1822.—"I have received an account of Putnam's Rock, which is in the river, opposite West Point. It was given to me by my friend Col. Tucker, of Gloucester, Mass. and the history, as connected with the American Revolution, cannot fail to be interesting.

"This famous rock, originally a native of the highlands above West Point, was situated on the extreme height of *Butter Hill*,* when the morning fog was descending from the hill it had a very beautiful appearance not much unlike a horseman's tent or hospital marquee riding on the cloud. It was a common amusement for the officers when off duty to roll large rocks from the sides of those hills. These often set others going with them, to the great terror of those persons who were below. One day when this laborious amusement was over, Col. Rufus Putnam proposed going up to take a peep off this curiously situated rock; it was found situated on a flat rock of great extent, and near the brink of a considerable precipice, and hung very much over it. Col. Putnam believed that it was moveable, and if once moved that it would roll over; and falling from twenty to fifty feet, commence its rout to the river. A few days after we formed a party of officers, with our servants, who took with them axes, drag-ropes, &c. in order to procure levers for the purpose of moving the rock, which we soon found was in our power. The levers being fixed with ropes to the ends of them all, Col. Putnam, who headed the party, ordered us to haul the ropes tight, and at the word *Congress* to give a long pull, and a strong pull, and a pull altogether. This we did, the levers fell, the rock rolled over, tumbled from the precipice, and took up its line of march for the river! The party then had the satisfaction of seeing the most majestic oaks and loftiest pines, bowing down in homage and obedience to this mighty traveller, which never stopped till it had reached the bed of the river, where it now lies on the edge of the flats and far enough from the shore for a coasting vessel to sail round it. The party followed after in its path, and were astonished to see that rocks of many

tons weight, and trees of the largest size, were ground to powder. On arriving at the river, the party embarked, and landed, to the number of sixty or seventy on the rock, when Col. Putnam broke a bottle of whiskey and named it "*Putnam's Rock*." I may have forgotten some of the minutæ of the transaction in the lapse of forty-three years; but it is a fact that the rock now in the river was removed from the extreme top of the *Butter Hill* by the officers of Col. Rufus Putnam's regiment, in the revolutionary war, in the service of the U. States, some time in the month of June, in the year 1778."

From an Ohio Paper of July 2.

Petrification.—An elderly gentleman, who recently died in Fayette county, Kentucky, previous to his death requested that his daughter's remains should be disinterred and deposited by the side of his own. His daughter had been buried about eleven years, in the county of Bourbon, Ky. After his decease, the old gentleman's request was complied with. To the great surprise and astonishment of those engaged in raising the daughter's remains her body was found to be entire, and of its full size. On a minute examination it was discovered to be perfectly petrified; its specific gravity was about the same as that of common lime stone.—The coffin was entirely decayed. Her countenance had undergone so small an alteration that her husband, it is said, on beholding her, fainted

In Petersburg, Va. a man is exhibiting serpents, and among them a rattlesnake four feet in length, five or six inches in circumference fangs and rattles entire, which is completely domesticated, and as obedient and affectionate to his master as a dog, and will coil himself up on his shoulder, caress him, and kiss his cheek. There is no disputing about tastes.

The sails and cordage of a first rate man of war require 180,000 lbs. of rough hemp for their construction; and it is said to average five acres of land to produce a ton of hemp: thus one of those monstrous towers of human ingenuity consumes a year's produce of 424 acres of land to furnish its necessary tackle.

The following curious circumstance, (says a London paper) which occurred during a fire at Bankside, may be relied on as a fact:—In one of the houses that appeared as one sheet of fire, the firemen perceived a cat sitting on some bags which were in the midst of the flames; the cat cried "mew! mew!" most bitterly finding her escape impossible. One of the firemen saw and heard her, cried out to Solomon, a Jew, who assisted them to work at the engine, "Solomon, y hear the cat calls out—Jew! Jew!" Solomon emphatically cried, "you shall not be disappointed the Jew, it, at the risk of my life, I can save you." I threw up a rope, to which there was a hook attached which fortunately stuck in the sack, and with a quick jerk, he pulled the sack from the midst of the flames and also the cat, whose hair was all singed from the fire. During an hour afterwards, whilst he worked the engine, the cat never quitted him, but held fast his shoulder, or sat near him on the engine; and afterwards brought his cat home to his own house.

A German Priest walking in procession at the head of his parishioners, over cultivated fields, in order to procure a blessing on their future crops, when he came to those of unpromising appearance, would pass saying, "here prayers and singing will avail nothing, this must have manure."

* This hill is 1520 feet above tide water, and 1302 above its base, according to Capt. Partridge.

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston, at \$2.50 per annum, in advance, or \$3.00 at the close of the year.

Vol. I.

BOSTON, SATURDAY, AUGUST 21, 1822.

No. 4.

CATTLE SHOW.

Exhibition of Manufactures, Ploughing Match, and Public Sale of Animals and Manufactures, at Brighton, Mass. on Wednesday and Thursday, the 9th and 10th of October, 1822, to commence at 9 o'clock, A. M. on each day.

THE Trustees of the Massachusetts Society, for the Promotion of Agriculture, encouraged by the patronage of the Legislature of this State, intend to offer in Premiums, not only the sum granted by the Government for that purpose, but also the whole amount of the income of their own funds. They, therefore, announce to the public, their wish to have a CATTLE SHOW, and EXHIBITION OF MANUFACTURES, &c. &c. at Brighton, on *Wednesday and Thursday, the 9th & 10th of October, 1822*; and they offer the following PREMIUMS:

FOR STOCK.

For the best Bull, raised in Massachusetts, above one year old,	\$30
For the next best do. do.	20
For the best Bull Calf, from 5 to 12 months old	15
For the next best do. do.	8
For the best Cow, not less than three years old	30
For the next best do. do.	20
For the next best do. do.	15
For the best Heifer, from one to three years old, with or without calf	15
For the next best do. do.	10
For the best Ox, fitted for slaughter, regard to be had to the mode and expense of fattening	40
For the next best do. do.	20
For the next best do. do.	20
For the best pair of Working Cattle	30
For the next best do. do.	25
For the next best do. do.	20
For the next best do. do.	15
For the next best do. do.	10
For the best pair of Spayed Heifers, not less than one year old	25
For the best Spayed Sows, not less than four in number, and not less than five months old	20

The claimant to be entitled to either of these two last premiums, must state the mode of operation and treatment, in a manner satisfactory to the Trustees.

For the best Merino Wethers, not less than six in number, having respect to form and fleece	20
For the next best do. do. do.	10
For the best native Wethers, not less than six in number do.	10
For the next best do. do. do.	5
For the best Merino Ram, do.	15
For the next best do.	10
For the best Merino Ewes, not less than five in number, do.	20
For the next best do. do. do.	10
For the best Ewe, not exceeding two years old do.	10
For the next best do. do. do.	5
For the best Sow	10
For the next best do.	5
For the best Pigs, not less than two in number, nor less than four months old, nor more than eight	10
For the next best do. do.	5

None of the above animals will be entitled to premiums, unless they are *wholly bred* in the State of Massachusetts.

For the best Ram which shall be imported into this State, after this advertisement, and before the 15th day of October next, of the improved Leicester breed of long woolled sheep, or of the best Dishley Breed, or of the fawn and long

woolled sheep of the Netherlands, the length and fineness of whose wool shall be found superior to those of our present breeds, \$50, or a gold medal of that value, at the option of the importer.

For the next best do. do.	10
For the best Ewe, of any of the said breeds imported under the same terms, and for the like superior qualities	30
For the next best do. do.	20

No animal, for which to any owner one premium shall have been awarded, shall be considered a subject for any future premium of the Society, except it be for an entirely distinct premium or for quantities different from those for which the former premium was awarded.

Any of the above Stock, when raised and still owned at the time of the exhibition, by the person who raised them, will entitle the claimant to an allowance of ten per cent. in addition. But Sheep, to be entitled to any of the above premiums, must be raised by the person entering them.

FOR AGRICULTURAL EXPERIMENTS.

To the person who shall raise the greatest quantity of Indian Corn on an acre, not less than seventy bushels	\$50
To the person who shall make the most satisfactory experiment, to ascertain the best mode of raising Indian Corn, in hills, in rows, or in ridges; not less than half an acre being employed in each mode, in the same field, the quantity and quality both of land and manure to be equal and uniform in each mode; all to receive a cultivation requisite to produce a good crop	30
To the person who shall raise the greatest quantity of Carrots on an acre, not less than six hundred bushels	20
To the person who shall raise the greatest quantity of Potatoes on an acre, not less than five hundred bushels	20
To the person who shall raise the greatest quantity of Parsnips on an acre, not less than four hundred bushels	20
To the person who shall raise the greatest quantity of common Beets on an acre, not less than six hundred bushels	20
To the person who shall raise the greatest quantity of Mangel Wurtzel on an acre, not less than six hundred bushels	20
To the person who shall raise the greatest quantity of Ruta-baga on an acre, not less than six hundred bushels	20
To the person who shall raise the greatest quantity of common Turnips on an acre, not less than six hundred bushels	20
To the person who shall raise the greatest quantity of common Turnips, after any other crop in the same season, being not less than four hundred and fifty bushels	20
To the person who shall raise the greatest quantity of Onions on an acre, not less than six hundred bushels	20
To the person who shall raise the greatest quantity of Cabbages on an acre, not less than 25 tons weight	20
To the person who shall introduce any Grass, not before cultivated in this State, and prove, by actual experiment, and produce satisfactory evidence of its superiority in any one quality, to any now cultivated	30
To the person who shall give satisfactory evidence on "Selling Cattle," not less than six in number, and through the whole season, together with a particular account of the food given, and how cultivated	30
To the person who shall make the experiment of turning in grass or peas as a manure, on a tract	

not less than one acre, and prove its utility and cheapness, giving a particular account of the process and its result 30 |

To the person who shall, by actual experiment, prove the best season and modes of laying down lands to grass, whether spring, summer or fall seeding, or preferable, and with or without grain on different soils 20 |

To the person who shall raise the greatest quantity of dry Peas on an acre, not less than thirty bushels 20 |

To the person who shall raise the greatest quantity of dry Beans on an acre 20 |

To the person who shall give proof of having produced the largest quantity of dressed Flax, raised on an half acre 10 |

To the person who shall take up in the season, on his own farm, the greatest quantity of good Honey, and shall at the same time exhibit superior skill in the management of Bees 10 |

For the best Cheese, not less than one year old, and not less in quantity than 100 pounds 10 |

For the next best do. do. 5 |

For the best Cheese less than one year old 20 |

For the next best do. do. 5 |

To the person who shall raise the greatest quantity of Vegetables, grain, peas and beans excepted, for winter consumption, of the stock on his own farm, and not for sale, in proportion to the size of the farm and stock kept, having regard to the respective value of said vegetables as food, stating the expense of raising the same, and the best mode of preserving the same thro' the winter 50 |

To the person who shall raise the greatest quantity of winter Wheat on an acre 30 |

To the person who shall raise the greatest quantity of spring Wheat on an acre 30 |

To the person who shall prove to the satisfaction of the Trustees, that his mode of rearing, feeding, and fattening neat cattle is best 20 |

For the best Butter, not less than fifty pounds 10 |

For the second best do. do. 5 |

For the best Side Leather, not less than five sides 10 |

For the second best do. do. 5 |

For the best dressed Calve Skins, not less than twelve in number 10 |

or the second best do. do. 5 |

For the best five barrels of superfine Flour, manufactured in the State of Massachusetts, from wheat raised in this state 25 |

For the greatest quantity of Butter and Cheese, made between the 15th of May, and the 1st of October, from not less than four Cows, the quality of the Butter and Cheese, and the number of Cows to be taken into consideration, and specimens to be exhibited at the Show, of not less than twenty pounds of each, and the mode of feeding, if any thing besides pasture was used 20 |

To the person who shall prove by satisfactory experiments, to the satisfaction of the Trustees, the utility and comparative value of the cobs of Indian Corn, when used with or without the grain itself, ground or broken 20 |

To entitle himself to either of the Premiums, under this head of Agricultural Experiments, the person claiming, must cultivate a tract of at least one acre in one piece, with the plant or production for which he claims a premium, (except flax) and must state, in writing, under oath of the owner, and of one other person, (accompanied by a certificate of the measurement of the land, by some sworn surveyor,) the following particulars:

1. The state and quality of the land, in the spring of 1822.

2. The product and general state of cultivation and quantity of manure, employed on it the year preceding.

3. The quantity of manure used the present year.

4. The quantity of seed used, and of Potatoes the sort.

5. The times and manner of sowing, weeding, and harvesting the crop, and the amount of the product, ascertained by actual measurement, after the whole produce, for which a premium is claimed, and the entire expense of cultivation.

And in relation to all vegetables, except Potatoes, Onions and common Turnips, the fair average weight of at least twenty bushels must be attested; and if there be hay scales in the town, in which raised, not less than three averaged cart loads must be weighed.

The claim under this head, together with the evidences of the actual product, must be delivered, free of postage, to Benjamin Guild, Esq. Assistant Recording Secretary of this Society, on or before the first day of Dec. next. The Trustees not intending to decide upon claims under the head of Agricultural Experiments, until their meeting in December.

FOR INVENTIONS.

To the person who shall use the Drill Plough, or Machine, and apply it most successfully to the cultivation of any small Grains or Seeds, on a scale not less than one acre

To the person who shall invent the best Machine, for pulverizing and grinding Plaster to the fineness of twenty-five bushels per ton, and which shall require no more power than a pair of oxen or a horse, to turn out two tons per day, and so portable that it can be removed from one farm to another without inconvenience

To the person who shall produce, at the Show, any other Agricultural Implement, of his own invention, which shall, in the opinion of the Trustees, deserve a reward, a premium not exceeding 20 dollars, according to the value of the article exhibited

In all cases proofs must be given of the work done by the Machine, before it is exhibited; and of its having been used and approved by some practical farmer.

FOR FOREST TREES.

For the best plantation of White Oak Trees, not less than one acre, nor fewer than one thousand trees per acre, to be raised from the acorn, and which trees shall be in the best thriving state, on the first of September, 1823

For the best Plantations of White Ash, and of Larch Trees, each of not less than one acre, nor fewer than one thousand trees per acre, to be raised from the seeds, and which trees shall be in the best thriving state, on the first of September, 1823

For the best Live Hedge made of either the White or Corkspear Thorn, planted in 1820, not less than one hundred rods, and which shall be in the best state in 1823

FOR DOMESTIC MANUFACTURES.

To the person or corporation, who shall produce the best specimen of fine Broadcloth, not less than 15-8 yards wide, exclusive of the list, 30 yards in quantity, and dyed in the wool

For the second best do. do. do.

For the best superfine Cassimere, not less than 3-4 yard wide, nor less than forty yards in quantity

For the second best do. do. do.

For the best superfine Sattinet, 3-4 yard wide, not less than fifty yards

For the second best do. do. do.

To the person or corporation, who shall produce the best specimen of Cotton Cloth, manufactured in this State, not less than fifty pieces

To the person who shall produce the best specimen of any other fabrics of Cotton, manufactured in this State, in public factories, not less than fifty pieces

FOR HOUSEHOLD MANUFACTURES.

For the best Woollen Cloth, 3-4 wide, not less than twenty yards in quantity

For the second best do. do.

For the best double milled Kersay, 3-4 yard wide, not less than twenty yards in quantity

For the second best do. do.

For the best Coating, 3-4 yard wide, and not less than twenty yards in quantity

For the second best do. do.

For the best Flannel, 7-8 yard wide, not less than forty-five yards in quantity

For the second best do. do.

For the best yard wide Carpeting, not less than thirty yards in quantity

For the second best do. do.

For the best 5-8 yard wide Stair Carpeting, not less than thirty yards in quantity

For the second best do. do.

For the best pair of Blankets, not less than 6-4 wide and 10-4 long

For the second best do. do.

For the best Woollen Knit Hose, not less than 12 pair in number

For the second best do. do.

For the best Men's Half Hose, (woollen) not less than twelve pair in number

For the second best do. do.

For the best Men's Woollen Gloves, not less than twelve pair in number

For the second best do. do.

For the best Linen Diaper, 5-8 yard wide, and not less than thirty yards in quantity

For the second best do. do.

For the best 4-4 yard Diaper, (for table linen) not less than thirty yards in quantity

For the second best do. do.

For the best specimen of Sewing Silk, raised and spun in this State, of good fast colors, not less than one pound

For the second best do. do.

For the best Linen Cloth, (for shirting or sheeting) one yard wide, and twenty-five yards long

For the second best do. do.

All the above Manufactures, except when of Cotton, must be of the growth and manufacture of the State of Massachusetts. And all Manufactures, when presented, must have a private mark, and any public or known mark must be completely concealed, so as not to be seen, or known by the Committee, nor must the Proprietors be present when they are examined; in default of either of these requisitions, the articles will not be deemed entitled to consideration or premium.

Animals, Manufactures, or Articles, may be offered for premium at Brighton, notwithstanding they may have received a premium from a County Agricultural Society.

It is understood, that whenever, merely from a want of competition, any of the claimants may be considered entitled to the premium, under a literal construction, yet if, in the opinion of the Judges, the object so offered is not deserving of any reward, the Judges shall have a right to reject such claims. Persons to whom premiums shall be awarded, may, at their option, have an article of Plate, with suitable inscriptions, in lieu of money. Premiums will be paid within ten days after they shall be awarded.

That in any case in which a pecuniary premium is offered, the Trustees may, having regard to the circumstances of the competitor, award either one of the Society's gold or silver medals in lieu of the pecuniary premium annexed to the several articles.

That if any competitor for any of the Society's premiums shall be discovered to have used any

dissimulous measures, by which the objects of the Society have been defeated, such person shall not only forfeit the premium which may have been awarded to him, but rendered incapable of being ever after a competitor for any of the Society's premiums.

All premiums not demanded within six months after they shall have been awarded, shall be deemed as having been generously given to aid the funds of the Society.

The Trustees of the Massachusetts Society for Promoting Agriculture, hereby give notice, that they intend, on the second day of the Cattle Show, viz: on the 19th day of October next, to give premiums to the Owners and Ploughmen of the three Ploughs, to be drawn by oxen, which shall be adjudged, by a competent Committee, to have performed the best work, with the least expense of labor, not exceeding half an acre to each plough, and of such depth as the Committee shall direct.

First Plough \$20	Second Plough \$12	Third Plough \$8
Ploughman 10	Ploughman 6	Ploughman 4
Driver 5	Driver 3	Driver 2

In each case, if there be no Driver, both sums to be awarded to the Ploughman.

The persons intending to contend for these Prizes, must give notice, in writing, to S. W. POMEROY, or GORHAM PARSONS, Esqrs. of Brighton, on or before the 2d day of October, so that proper arrangements may be made for the purpose. No person, will, on any consideration, be admitted without such notice. The competitors will also be considered as agreeing to follow such rules and regulations as may be adopted by the Committee, on the subject. The ploughs to be ready to start at 9 o'clock, A. M.

The result of the last Ploughing Matches at Brighton, and the satisfaction expressed by so many of their agricultural brethren, will induce the Society to continue these premiums annually, in connexion with the Cattle Show, as an efficacious means for exciting emulation and improvement in the use and construction of the most important instrument of agriculture.

Persons intending to offer any species of Stock for premiums, are requested to give notice thereof, either by letter (post paid) stating the article, or to make personal application to Mr. JOSEPH WINSHIP, at Brighton, on or before the 8th day of October, and requesting him to enter such notice or application; so that tickets may be ready at 9 o'clock, on the 9th. No person will be considered as a competitor, who shall not have given such notice, or made such application for entry, on or before the time above specified.

All articles of manufactures must be entered and deposited in the Society's Rooms, on Monday, the 7th of October, and will be examined by the Committee on Tuesday, the 8th, the day before the Cattle Show; and no person but the Trustees shall be admitted to examine them before the Show. The articles so exhibited, must be left till after the Show, for the satisfaction of the public.

The applicants will be held to a rigid compliance with this rule relative to entries, as well as to the other rules prescribed.

The examination of every species of stock, (except working oxen) will take place on the 9th; and the trial of Working Oxen, examination of Inventions, and Ploughing Match, on the 10th of October.

The Trustees also propose to appropriate, on the second day of the Cattle Show, their Pens for the public sale of any Animals, that have been offered for premium, and also of any others, that are considered by them, as possessing fine qualities; and their Halls for the public sale of Manufactures. Both sales to take place at half past eleven o'clock, precisely. And for all Animals or Manufactures, that are intended to be sold, notice must be given to the Secretary, before 10 o'clock of the 10th. Auctioneers will be provided by the Trustees.

By order of the Trustees,

J. LOWELL,
J. PRINCE,
G. PARSONS,
E. H. DERBY, } *Committee.*

January, 1822.

From the Boston Daily Advertiser.

CONSTRUCTION OF STABLES.

Most of the horses brought into this town from the country, become soon diseased, generally in the course of the first week, and frequently in 24 or 48 hours after they are placed in our stables. It has been frequently asked what can be the cause of this sudden alteration in the health of the animal, and it has almost as frequently been answered, a change of air and of food. There is no doubt a change of food has some influence, but the effect is principally attributable to a change of air. It is not however the kind of change, that is generally supposed. It is not the bringing horses from a fresh atmosphere to a salt one, that produces the disease I allude to. It is the bringing them from a pure atmosphere, and confining them in crowded stables, where the air being vitiated by respiration, and the effluvia from animal bodies, a malignant quality, which being inhaled by horses unaccustomed to it, soon deranges the system and generates disease; and so long as our stables are constructed, as they now are, so long will our country horses be sick, when brought into them. We have all of us heard of jail fever, hospital fever, plague and typhus; and much has been said about the domestic origin of yellow fever, but what jail, hospital or prison ship; or what situation in our streets, or about our wharves, can be found, where the air is so vitiated as in a common stable? Imagine for instance 30 or 40 horses confined in a space 30 by 30 feet, and 9 feet high, (the scaffold is generally about 9 feet from the ground) surrounded by a brick wall, without windows, and no ventilators through the roof; and no outlet for the hot air, except at the doors, and those closed at night; and then consider the fact as stated by Dr. Hales, that a man cannot live in 74 cubical inches of air, one minute, without danger of suffocation. It is obvious, that a horse so situated, must breathe the same air over and over again, and not only the air which has repeatedly passed through his lungs, but that which has been breathed many times by other horses, and is filled with exhalations, arising from animal secretions and excretions; and perhaps too, the planks and timbers of the very stall he stands in, may have been saturated, for years, with excrementitious matter, which can emit only noxious effluvia, or what is called animal miasms.

It has been stated by a writer of some eminence, that three thousand men confined in the

compass of one acre of ground, would make an atmosphere of their own steams, seventy feet high, which would soon become pestilential, if it were not dispersed by the winds. After considering these facts, who can doubt what generates disease in horses brought into our stables from the country? The only doubt that naturally suggests itself is, how our horses get along so well as they do. After getting over their first sickness, or seasoning, as it is called, (which requires more or less time, according to the constitution of the horse, and the stable in which he is placed) they go on tolerably well. Their constitutions become assimilated to their situation, as to the air which they breathe, and its effects are not so injurious; in the same manner as a man, may become so accustomed from habit, to the use of tobacco, opium, and arsenic, that they will not make him sick, yet none will say, that these are not injurious to the human constitution; and I believe few will say, when the subject is properly understood, that the air in our stables is not equally so to the animal.

In making these remarks, I have but one motive, which is to draw the attention of the public to this subject, in hopes that an alteration in the construction of our stables may be the consequence. We have many excellent buildings in this town, occupied as stables, and with a few alterations, they might be made very healthy and comfortable dwellings, for horses.

In constructing a stable, the first object ought to be a proper system of ventilation. This may be effected in the following way. Let a hole 3 by 4 inches be knocked through the brick wall, immediately above the head of each horse, and another of the same dimensions opposite to it, and parallel with the floor of the stall. This will occasion a perfect and constant ventilation. As it is the property of hot air to ascend, every time the horse makes an expiration, the air expelled from his lungs, being more rare than the surrounding atmosphere, will go out at the upper hole, and a corresponding quantity of pure air will come in at the lower hole.

No danger is to be apprehended from cold air coming in at the upper hole, upon the head of the horse, as the current will constantly be turned upwards. The rarified and unwholesome air will escape at the upper hole, and the wholesome air will come in at the lower.

As some stables may be so situated, as to render this method of ventilation impracticable, I would recommend, where this is the case, that one, two, three or four openings be made through the roof. The number ought to be in proportion to the length and size of the stable. This may be done in the following way. Let a hole be cut through the scaffold about 3 feet square, and another directly over it, through the roof, about 2 feet square, and let a box be inserted, open at each end, of a shape and size, to correspond to these two openings, and sufficiently long to extend from the under side of the scaffold, through the roof. Then let holes be cut through the doors, or through some convenient parts of the stable, on a parallel with the floor, of equal number and dimensions, as those through the roof. By this method a regular and systematic ventilation will be produced. If any one doubts the justness of these remarks, and believes that our present method of stabling a good one, and that horses ought to

be kept in a hot air, and covered up with woolen blankets, let him try the experiment upon himself; let him sleep in a heated room, with ten or fifteen others, covered up with clothes, sweat it out for the night, and try the condition he will be in for any kind of employment whatever.

I cannot refrain here from making one or two remarks upon the very common, but very absurd practice of blanketing horses in the stable, though this is a subject which more properly belong to the management of horses than the construction of stables.

It must be obvious to every one, who reflects at all upon this subject, that if a horse requires one blanket in a warm stable, he ought to have two when he goes out in a cold storm. Instead of this, when the horse is taken from the stall, his blanket is thrown off, and he is exposed perhaps for the day to the inclemency of the weather, and frequently without much exercise to counteract the effects of cold. Even the constitution of a horse cannot withstand this treatment. He soon becomes infirm, decrepit, and broken down. His usefulness is diminished and his life shortened by this kind of management.

From the Rhode Island American.

FARMERS—ATTEND.

James Sisson, Esq. who lives at Warren Neck, about three miles from the village of Warren, is well known to the public as an enterprising Agriculturalist. He is always seeking improvements in what is most useful to his fellow-citizens, viz. Orchards, the introduction of new kinds of Grain, the best mode of cultivating his farm, &c. He imported from Bremen, in November, 1820, two pairs of the largest kind of Geese, supposed to be the largest in the world, weighing when fattened, 20 pounds, and it is confidently asserted, some weigh 30 pounds. At first he was rather discouraged, as they would not eat Indian corn, and the spring following they sat early and both Geese reared but one to maturity. That one, however, this spring, brought off two litters, and the two old pairs each brought up a litter; he now has 17 young and 5 old ones, all perfectly white and healthy, and of full size. They feed and set as well as any of our common Geese; the young come off healthy and strong, and yield about double the quantity of feathers. I was at his farm a few days since, and was highly gratified in viewing on the lawn directly in front of the house, two beautiful flocks of snowy whiteness (he has the common geese, feeding near them, and they resemble ducks in point of size) and I have no hesitation in recommending to the farmers of New-England that they introduce this valuable breed of poultry into their barn yards. Mr. Sisson will dispose of a few pairs, if applied for soon, and the opportunity ought not to be neglected.

A Friend to Agriculture.

New Covering for Floors.—A new material has been introduced and is becoming fashionable in Philadelphia as a covering for floors. It is made of paper, is said to be very handsome, as it may be fashioned in a great variety of patterns, is quite durable, and is only one quarter as expensive as Carpets or Oil Cloth.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.

WORKING BULLS.

"The bull is naturally vicious, and often becomes so mischievous as to endanger many valuable lives; an evil which we conceive might be remedied by training him to labor. For, being the only beast of his size which is indulged in idleness, and as he possesses equal strength with the ox, we doubt not, but if he were properly worked, and allowed to indulge his desire during the breeding season, he would, by being inured to labor and attended by mankind become gradually tame, and harmless, as the horse, or any other naturally vicious animal. Several experiments, indeed, have been made for this purpose; and from their successful result, we think the practice of working bulls may be advantageously adopted; especially as these animals are not only broken in with little difficulty, and work well, but also because they recover from fatigue much sooner than an ox."—*Complete Grazier*.

REMEDY AGAINST ANTS AND SPIDERS.

Mr. Clutterbuck, Jr. of Watford, washed the walls of his hot-house with a painter's brush, dipped in a solution made of four ounces of corrosive sublimate, in two gallons of water; and since that application, neither the red spider, against which this remedy was employed, nor ants have made their appearance.

Domestic Encyclopedia.

CRICKETS.

An easy method of destroying crickets is to place phials half full of beer, or any other liquid near their holes, whence they will crawl into them and cannot escape. Cats are very fond of crickets; but the great quantities they consume often occasion their death. Hence it is more advisable to destroy these insects, either by pouring hot water into the holes through which they retreat, or exposing boiled peas or carrots, mashed up with quick-silver, in places which they frequent. Another mode of exterminating them, consists in placing pea straw near their habitations, and then immersing them in water, together with this straw, to which they are peculiarly attached.—*ibid.*

REMEDY AGAINST VERMIN WHICH INFEST SWINE.

Mr. Joseph W. Ballard, of Mount Pleasant, Isle of Wight County, Virginia, directs, in cases where hogs are infested with vermin, to take "a little tar, and grease of any kind sufficient to make the tar quite thin, then pour it over the hogs, when fed, sufficiently so as to have them quite smeared with the tar; this may be repeated often in the summer and fall, as I conceive it to be an excellent thing for the health of the hogs—or in good weather you may give to each hog a small table-spoonful of sulphur in their food, or in damp weather have them well sprinkled with strong wood ashes; either of these remedies will prevent or destroy the vermin."—*American Farmer*.

SPENT TAN OR TANNER'S WASTE.

This substance is, we believe, valuable for agricultural purposes, and have therefore been sorry to see a great deal of it accumulating in useless piles about tanner's yards, and scattered about highways and commons. It is probable,

however, that if it is employed as a manure in a crude state, it may not prove immediately useful. It would be likely to retain something of the *gallic acid*, which is we believe unfriendly to vegetation. This acid, however, may easily be neutralized by mixing with the bark a quantity of quick lime.

The *Complete Grazier* informs us that "Oak bark, or, (more correctly speaking,) tanner's waste, may be accumulated into small heaps, and mixed with lime and a sufficient degree of water to keep it moist, and promote its decomposition and putrefaction. It is an excellent manure for cold stiff soils, whether arable or grass lands; but for the latter it should be made to approach the nature of vegetable mould as much as possible. The best time of spreading it on grass lands is shortly after Michaelmas, (beginning of October) that the winter rains may wash it into the ground; as, if it be applied in the spring it will burn the grass, and exhaust rather than improve the soil for that season."

It has been said that if boxes are made round peach trees about one foot in height, to hold about a peck, and these filled with the bark taken from tan vats, pressed a little together, the trees will remain free from worms about their roots, which often prove fatal to them. Spent tan, likewise, we have been told, will preserve fruit trees from the curculio, (a small worm which is found in perhaps one half the apples and pears raised in New England.) We apprehend, however, that if this substance is intended as a preservative against insects, it should be applied in a fresh state, and without being mixed with lime, as it is probably the acid which proves destructive to insects, and the acid would be destroyed by quick lime.—Another use of spent tan spread about the roots of fruit trees is to prevent a too early vegetation in the spring, and thus the buds and blossoms escape early frosts.

WEIGHT OF SWINE.

The *Complete Grazier* gives the following rules to guard the unsuspecting purchaser against imposition in buying swine:—"When swine are fat, it appears from actual experiments that every twenty pounds of live weight will, when killed, produce from twelve to fourteen pounds clear weight. Where the hogs do not exceed twelve stone of fourteen pounds to the stone, the weight will be twelve pounds; if they be of a larger size, it will be upon an average about fourteen pounds; so that if a farmer or breeder weigh his beasts while alive, he will be enabled to ascertain the net profitable weight when dead; and likewise by weighing the hogs every week to fix the best time for disposing of them to advantage; because, as soon as an animal ceases to acquire that daily increase, which makes it beneficial to keep him, the best step that can be followed is to sell or slaughter him without delay."

MANGEL WURTZEL.

A writer in the *Farmer's Journal*, an English periodical publication of much merit, in treating of the culture of Mangel Wurtzel, observes that "Having noticed the issue of an innumerable quantity of small lateral fibres from the sides of this plant during its vegetation; considering them conductors of nutriment, and that putres-

cent vegetable or other matter was the best pabulum, a compost of dung and soil (prepared in autumn) was ploughed in with the wheat stubble; the succeeding ploughings, harrowings, &c. well mixed it with the soil. This was the largest crop I ever cultivated or have seen; which I attribute, in a great measure, to the intimately mixing the manure with the soil." This remark," says the editor of that paper, "is doubly important, as it shews that autumn ploughing, and broadcast dunging (performed in autumn) are best for mangel wurtzel."

SCRAPINGS OF ROADS, AND MUD FROM SWAMPS, &c.

Some little knowledge of chemistry seems indispensable for the proper management of manures. A writer in the *Farmer's Journal* states in substance that turnips manured with scrapings from the city road, consisting chiefly of ballast ground to powder, enriched with the droppings of cattle, grew very vigorously until the bulbs should have swelled, when they all turned yellow and died, notwithstanding they were, from time to time, well watered. The same writer says, "The experiments of Mr. Malcolm prove that scrapings from gravel roads may be generally suspected of containing qualities injurious* to vegetation, although the droppings of cattle, &c. mixed therewith, give a temporary vigor to the plant. On the other hand, scrapings from chalky roads, or any calcareous stone may be very useful on suitable soils."

We have likewise known swamp-mud, apparently rich, but mixed with sulphate of iron (copperas) (as was manifested by that kind of scum on the water drained from the swamp which denotes the presence of that metal) disappoint the expectations of farmers, who used it for manure. This may be easily accounted for. "Vitriolic impregnations," according to Sir Humphrey Davy, "in soils where there is no calcareous matter, are injurious, probably in consequence of their supplying an excess of ferruginous matter to the sap. Oxide of iron in small quantities forms a useful part of soils, and probably is hurtful only in acid combinations." The remedy, in such cases, is simple, and is thus pointed out by Sir Humphrey Davy. "If on washing sterile soil it is found to contain the salts of iron, or any acid matter, it may be ameliorated by the application of quick lime. A soil of good apparent texture from Lincolnshire, was put into my hands by Sir Joseph Banks, as remarkable for sterility; on examining it, I found that it contained sulphate of iron; and I offered the obvious remedy of top dressing with lime, which converts the sulphate into a manure."† The sulphuric acid of the sulphate of iron, combines with the lime and forms sulphate of lime, which is Gypsum, or Plaster of Paris.

GOOD HINTS.

The following, extracted from an Address by Mr. James Garret, President of the Fredericksburgh Agricultural Society, delivered before that Society at an anniversary meeting, may be found well worth the attention of those whom it may concern.

"I here beg leave to offer, (although I know that I shall receive no thanks for it) a sugges-

* Probably sulphate of iron (copperas) or some other combination of acids with metals.

† Agricultural Chemistry, p. 141, Philadelphia ed.

tion to all makers of patented agricultural implements. This is to calculate well before they fix their prices, whether they could not make greater profits by selling at lower rates. I know a maker of cast-iron ploughs, for instance, who, although he has considerably reduced his prices, still receives at least twenty cents per pound for them, as I have ascertained by actual weighing, when common castings, the monopoly of which is not secured by patent, sell from six to eight cents! This difference, I think, may well be called an exorbitant exaction; and to my certain knowledge it has prevented many farmers from using, notwithstanding they highly approve them. Now, although I would be one of the last men in the world to withhold liberal encouragement from new inventions, yet I must say, that some of the authors of them appear to require other restraints than those which their own consciences and our patent law afford.—That any very useful discovery should enrich the man who makes it, I think all quite fair; but his riches should result rather from the exclusive right of selling his invention, and the products thereof, than from his extravagant profits on the articles which he vends beyond what they would command if he had no monopoly.*

Extracts from an Address delivered before the Philadelphia Society for promoting Agriculture, at its annual meeting on the 15th Jan. 1822.

"It was stated two years ago by one of the Vice-Presidents of this Society, that the average crop of wheat in Lancaster county, which is considered the richest in the state, did not probably exceed fifteen bushels per acre. Now the average of all France is more than eighteen bushels—the average of all England twenty-four—and in some counties, as in Middlesex and the Lothians, forty. With regard to rents, it is not easy to speak with accuracy. If we except the alluvial meadows near this city, which rent for nine or ten dollars per acre, I should not estimate the average rent of cleared land with improvements within the district just mentioned, at more than two or three dollars. In Italy, in England, and in Scotland, lands not particularly favored by vicinity to markets, rent for from sixteen to twenty dollars, and in the neighborhood of large cities, from thirty to forty dollars.

The causes of this inferiority may be discovered in two characteristics of our farming—a disproportionate capital, and an inefficient cultivation. The first is a striking deficiency. Agriculture, though a very common, is not, I think, a favorite pursuit in Pennsylvania. It attracts few from the other classes, and its ranks are rather thinned by desertion than recruited by volunteers. The enterprising shun it for its inactivity; the gay for its loneliness; the prudent from its unproductiveness; so that although a great proportion of the wealth of the state is fixed in land, an exceedingly small capital is devoted to farming. We too often exhaust our means in clearing or purchasing a farm, leaving scarcely any resources for stocking and cultivating it. Now an English farmer, with a certain capital, rents a farm, as a manufacturer rents a house, and devotes his capital to extract from it the greatest possible produce. Accordingly his proceedings seem almost incredible to the possessors of large American farms. It has

become a settled maxim of English husbandry, that before occupying good arable land, a capital of from thirty to forty dollars per acre is necessary. On an estate of three hundred acres, therefore, a farmer begins by expending in preparations nine thousand dollars; and his annual disbursements in labor, manure and other articles, are about five thousand dollars a year. His operations are all on a proportionate scale. To contract to pay a rent of twenty or thirty thousand dollars; to expend in a single year on lime alone, eleven thousand dollars; to pay two thousand dollars a year for rape cake to manure turnips; to make a compost heap costing four thousand dollars; such are the combinations of wealth and skill to produce good husbandry. These we cannot, and we need not imitate. But they may teach us that we should measure our enterprises by our means; and that an ill managed farm can no more be profitable than an empty factory. Men praise the bounty of nature. It is much safer to rely on her justice, which rarely fails to reward our care and avenge our neglect. Our farms, then, though small, are generally too large for our capitals; that is we work badly too much ground, instead of cultivating well a little. It is wonderful, indeed, how profusely a small spot of ground will reward good husbandry. There are in Italy hundreds and thousands of people, living on farms of from four to ten acres, and paying to the owner one third or one half the produce. The whole straw for the Leghorn bonnets, by the exportation of which in a single year five hundred thousand dollars were gained, would grow on two acres. There are in Switzerland some hill sides, formed into terraces, which have sold for two thousand dollars an acre; and in fortunate spots for gardening, as near London, a single acre will yield a clear profit of from eight to nine hundred dollars a year. These examples may perhaps explain, how without the great capitals of England, and without diminishing our farms, we may gradually render them richer and more productive by judicious culture."

BARN YARDS AND STERCORARIES OR MANURE HEAPS.

The following humorous exposition of the faults of some farmers, as respects the economy of their barn yards and stercoraries, is extracted from an Address to the Massachusetts Agricultural Society, by the Hon. Josiah Quincy.

"As we proceed to the farm we will stop one moment at the barn yard. We shall say nothing about the arrangements of the barn. They must include comfort, convenience, protection, for his stock, his hay, and his fodder, or they are little or nothing. We go thither for the purpose only of looking at what the learned call the stercorary, but which farmers know by the name of the manure heap. What is its state? How is it located? Sometimes we see the barn yard on the top of a hill, with two or three fine rocks in the centre; so that whatever is carried or left there, is sure of being chiefly exhaled by the sun, or washed away by the rain. Sometimes it is to be seen in the hollow of some valley, into which all the hills and neighboring buildings precipitate their waters. Of consequence all its contents are drowned or water soaked, or what is worse, there having been no care about the bottom of the receptacle, its wealth goes off in the under strata, to enrich possibly the antipodes.

"Now all this is to the last degree wasteful, absurd and impoverishing. Too much cannot be said to expose the loss and injury which the farmer thus sustains. Let the farmer want whatever else he pleases—but let no man call himself a farmer, who suffers himself to want a receptacle for his manure, water-tight at the bottom, and covered over at the top, so that below nothing shall be lost by drainage; and above, nothing shall be carried away by evaporation. Let not the size of his manure heap be any objection. If it be great, he looses the more, and can afford the expense better. If it be small, this is the best way to make it become greater. Besides, what is wanted? An excavation, two or three feet deep, well clayed, paved and "dishing," as it is called, of an area from six to thirty feet square, according to the quantity of the manure; over head a roof made of rough boards and refuse lumber if he pleases."

CURE FOR THE BITE OF THE RATTLESNAKE OR OTHER VENOMOUS ANIMAL.

We have had the pleasure of a conversation with Dr. Joseph Moore, of Gibsonport, Miss. who informs us that, during eighteen years residence in that climate, there have come under his particular care thirteen cases of the bite of the rattlesnake and moccasin, (the latter of which is more venomous than the rattlesnake) and that he has found the following a certain and immediate cure. The remedy was introduced into Europe from Asia, by Sir William Jones, and has the confidence of the medical faculty, wherever it has been applied.

Give to a grown person a teaspoonful of the volatile spirit of sal ammoniac, or what is commonly called spirits of hartshorn, in half a wine glass of water, every half hour, until the symptoms disappear, binding at the same time a linen cloth, of three or four thicknesses, wet with the spirits, unmixed with water, to the wound; the cloth to be wetted in the spirits every five minutes.

If the wound has been given some hours before the application can be applied, it should be scarified freely round the bite with a sharp knife or lancet, before the wet cloth is laid on.

The most severe and obstinate cases have been known to yield to this remedy in a few hours.

Very great care ought to be taken that the spirits of hartshorn should be kept tightly corked; for, if exposed to the air, it soon loses its efficacy.—*Village Record.*

EFFECTUAL CURE FOR THE CHOLERA MOREUS.

Take four ounces of chipped log wood, and one ounce of cinnamon, put them in three pints of water, and boil them down to a pint and a half; then strain it and add a pint of brandy, and four ounces of loaf sugar; then simmer it over a slow fire for a short time, and then put it up for use. For a grown person take a table spoonful, and a child a tea spoonful. Our informant, a respectable gentleman from Upper Marion Township, Pennsylvania, states that it has been used in his family, also by several of his neighbors, and in every instance it has been found to give almost immediate relief.

Philadelphia Union

A correspondent informs us that if land is infested with white weed, it will be effectually destroyed in two years by pasturing sheep on it

* See American Farmer, May 3, 1822.

NEW ENGLAND FARMER.

BOSTON:—SATURDAY, AUGUST 24, 1832.

Candles with wooden wicks.—A writer in the *Aurora*, states the result of an experiment he has made with wood for the candle wick. The wood was of a cypress shingle, split to the size of a rye straw and made round, so that the coat of cotton which was applied, might be more easily put on by rolling the stick upon a card which contained the cotton, and which had been previously well carded. The candle with the wooden wick lasted 7 hours while one of the same size (six to the pound) with cotton wick, lasted but 5 hours. Agreeably to this experiment, a pound of candles will last forty-two hours, when they would only last thirty made the usual way.

SAIL CLOTH.—We are pleased to be able to announce the successful establishment of a manufactory of Sail Cloth, on a new and improved principle at Stoneham, near this city, by a Mr. Jounson. Bolts of different numbers of Mr. J's manufacture have been sent for inspection to the Charlestown Navy Yard, whose fabric has been declared by competent judges, to be decidedly superior, in beauty and strength, to any article of this kind ever exhibited in the U. States.—*Boston Statesman*

WOOL.—A correspondent informs us, that from January 1st to June 30th, of the present year, there has been imported into this District from foreign ports, *one hundred and ninety seven thousand nine hundred and four pounds of Wool.* A very sound reason for our farmers to grow more of that useful article, as it will command readily the money, from thirty-two to sixty cents per pound.—ib.

The Long Island Farmer states, that eleven pounds of well washed fine white wool was sheared, a few days since, from a merino buck belonging to Mr. James Scott.—*N. Y. Gazette.*

Canada Thistle.—Mr. Butler states from his own experience, for the information of farmers and agriculturists, that if the Canadian thistle is cut down in this month it will decay, for these reasons: the seed will be rendered abortive, and the stock, which is hollow, will fill with water and destroy the plant.

Ulster Picteum.

Easy cure for the Ague.—When the fit is on, take a new laid egg in a glass of brandy, and go to bed immediately. This very simple receipt has cured a great many, after more celebrated preparations have proved unsuccessful.

Arsenic.—A man, says an English paper, was poisoned in a very singular manner. His physician prescribed for him a dose of arsenic and sent it to a druggist to be put up. The druggist having adjusted his scales with the proper weights, turned to get the arsenic; while in the act of getting it, a worm or caterpillar crawled up the scales in which the weights were, and in this situation added its own weight, which occasioned the dose to be too large, and thus destroyed the patient.

Dense Population.—At Pawtucket, near Providence, on an area of from eighty to ninety acres of land, there are *three hundred and seventy seven families, and two thousand three hundred and ninety three individuals.*

A friend to our establishment, and a member of the Massachusetts Agricultural Society, having suggested to us the propriety and probable utility of republishing the Notice of the Cattle Show, List of Premiums, &c. with which this number commences, we have given it a place to the exclusion of some others articles intended for this day's paper. We are happy in being in any degree instrumental in furthering the views of the Society; and those to whom our first article conveys nothing *new*, will excuse its republication when they are informed that we have distant subscribers, who, probably, have not seen the list of premiums, and who, perhaps, may yet be induced to become competitors for those rewards, with which the bounty of the government and the liberality of the Trustees of the Society propose to remunerate superior skill and industry in various departments of Agriculture and Domestic Manufactures.

Rye Coffee.—A writer in the *N. E. Palladium* of the 23d inst. with the signature "A Middlesex Farmer," has controverted the assertions and theories of a "Friend to Health," (published in our last No. p. 19,) relative to the injurious effects of rye when used for Domestic Coffee, &c. We do not wish to condemn one of the staple articles of our country without at least giving it a fair trial, and its advocates a full and impartial hearing. We shall, therefore, give the remarks in favor of Rye Coffee, by "A Middlesex Farmer," in our next number.

COOKING FOOD FOR CATTLE.

(Continued from page 23.)

A great advantage, which results from preparing food for cattle by steaming or boiling is obtained by its converting *water into solid food.* This may appear incredible to those who have either not thought at all, or thought somewhat superficially on the subject. A few grains of reflection however, together with a spice or two of philosophy may serve to show that water is capable of affording a great deal of nutriment either in a liquid or solid form. We pass over the fact that some plants will grow with no other nourishment than what is afforded by water and air, and proceed to show that much nutriment for animals may be obtained from water, when combined with other substances, by the agency of heat.

It is a fact, which will be acknowledged as soon as suggested that a pound of Indian meal, or of rice, when boiled, gives more nourishment to man, or beast, than several pounds in a raw state. Count Rumford says, "From the result of actual experiment it appears that for *each pound* of Indian meal employed in making hasty pudding, we may reckon *three pounds nine ounces* of the pudding."* And again "Three pounds of Indian meal, three quarters of a pound of molasses, and one ounce of salt, having been mixed with five pints of boiling water, and boiled six hours produced a pudding, which weighed *ten pounds and one ounce.*"† The gain of weight in boiling rice is still greater. Now it is evident that these dishes must contain much more nourishment, as well as more substance after having been cooked than could have been derived from their materials, if swallowed in a raw state.

But we will give another example to show that water is not only capable of being converted by heat into solid nutriment, but may even be made to compose

a constituent part of sugar, one of the most nutritious of all substances. It is remarked by De Saussure that "As starch boiled in water with sulphuric acid, and thereby changed into Sugar, increases in weight without uniting with any sulphuric acid or gas, or without forming any gas we are under the necessity of ascribing the change *solely to the fixation of water.* Hence we must conclude that *Starch sugar is nothing else than a combination of starch with water in a solid state.* The sulphuric acid is not decomposed, or united to the starch as a constituent.* Should any person still doubt whether water can exist in a solid state, combined with other bodies let him take the trouble to weigh a small quantity of quick lime, then slack it with water, and mark the increase of its weight. If then *solid nourishment* can be obtained from water by any cheap and practicable process, that husbandman must be blind to his own interest who omits to make use of such process.

Having thus as we conceive settled the point that it is good economy to steam or boil food for cattle, we will now attend to some enquiries respecting the best mode, of executing such processes. Our observations will be plain and practical; and should we fail to point out the best methods of effecting our object, we may perhaps be of service by directing the attention of others to the subject, who may be more capable of its investigation.

We are not fully acquainted with all the improvements in producing steam for steam engines and other purposes. We shall however advert to some inventions of the kind which appear to us simple as well as ingenious and perhaps superior to the means generally employed for similar uses.

A boiler invented by Count Rumford, and presented to the French National Institute is described in Aikin's *Athenum.* The substance of the description is as follows.

This boiler was made on a small scale being a copper cylinder only twelve inches in diameter, and as many in height, closed at top and bottom with circular plates. From the bottom seven tubes projected downward, each nine inches long, and three inches across, open next the cavity of the boiler and closed at their further extremities. From the top of the boiler a short tube arose six inches in diameter, and three inches high, shut at the top by a copper plate, through which passed one tube for the safety valve, another to convey the steam when wanted, and a third to admit water from the reservoir to supply the evaporation. This last tube passed downwards to within an inch of the bottom plate, where it was furnished with a cork and floating ball, that was so placed as to keep the water six inches deep in the cavity of the boiler above that in the tubes.† The furnace in which this boiler was placed was of sheet iron three inches high, and seventeen inches in diameter, lined with masonry, which is not particularly described; but as the grate is mentioned to be but six inches in diameter, it is probable that the cavity of the fire-place was of a conical shape from it to the bottom of the seven tubes.

Count Rumford reports that the boiler exceeded his expectations—he supposes that a boiler made in this form would have more strength in proportion to the surface exposed to the same internal pressure than one in the usual shape, and that it would be less liable to

* See a *Treatise on Manures*, printed in the same volume with Sir Humphrey Davy's *Agricultural Chemistry*, Philadelphia Edition.

† This contrivance is probably the same, or bears some analogy to what Mr. Smith calls the "self-supplying valve," which is apt to get out of order." See our last No. p. 23, 24 col.

* Rumford's *Essays*, vol. 1, page 253, Boston Edition.

† Rumford's *Essays*, page 261.

loss of heat from cold air coming in contact with its internal surface.

When a boiler of this kind is constructed on a large scale, the Count mentions that the seven descending tubes may be made of cast iron, and the rest of the boiler sheet iron, or copper; and thinks that when of this construction, it will cost less than one of equal surface of the usual form.

A Mr. Lloyd obtained a patent in England for a boiler, which is described in substance as follows:

The bottom of Mr. Lloyd's boiler is introverted, so as to form a cavity which would nearly hold as much as the boiler itself, if it were reversed; the sides of this cavity are somewhat conical, and from the top a pipe passes out at one side through the cavity of the boiler to the air; the whole boiler or kettle is surrounded by an external case, a little distant from it all round, closed at top, and having a small opening at the side to give vent to the smoke. The small pipe adds somewhat to the effect, but is not absolutely necessary. For large boilers the cavity at the bottom need not be so large in proportion as that described. If it rises into the boiler a third of its depth, it will probably be sufficient. The flame and radiant heat of the fuel is reverberated in all directions in the cavity of the hollow bottom, and must (says the inventor) have much more effect than what can be produced by its unconfined lateral action against the external sides of a number of upright tubes, however well arranged.

A patent for "a new method of applying fire for the purpose of heating boilers," &c. obtained in England by Mr. Thomas Rowntree, has the following description:

"For heating of coppers, boilers, furnaces, ovens, and stoves, my fire place is much smaller than heretofore made use of for the same sized copper, boiler, furnace, oven or stove. Instead of placing my fire-place, according to the common practice, immediately under the boiler, or other vessel, I place it at the front side or end, as I see most convenient, in such a manner as to oblige the flame to rise in the front-side or end, and pass all round the vessel, &c. while at the same time it strikes the bottom of the vessel, &c. without suffering the flame to pass off in a flue, or flues, as it usually does in the common way, and by that means sending the heat into the flues, instead of its being used where it ought to be, namely, on the vessels, &c.: this my method effectually prevents; for by means of a small perpendicular, or other opening into a box or trap, which I call a reservoir, and which I place horizontally or diagonally, as the situation may require, and is made of iron, brick, stone, or any other material capable of bearing heat, where a valve is placed, riding on centres or otherwise, and standing in a diagonal or other direction, as is found most convenient, the flame is returned or impeded in its progress to the chimney, and made to descend below the bottom of the vessel, and pass out at the bottom, top, or side of said box, trap or reservoir, into the common chimney. This reservoir is placed between the vessel, &c. and the chimney. To the opening which admits the flame into the reservoir, are affixed, when necessary, sliders, registers or stops, which serve to increase or diminish the heat. The valve in the reservoir is for the same purpose in another degree, which more immediately appertains to increasing or diminishing the draught, which it does by moving the said valve into different positions, as the speed of the operation may require."

The above described boilers, and method of applying heat to them, or something like them, may perhaps be

* For further explanation of this method, see *Witch's Domestic Encyclopedia*, Art. *Boiler*; *Iberville's Repository of Arts*, vol. xiv, p. 1. First Series.

found expedient for farmers, who perform their operations on a large scale. But for common use we believe a five pail kettle so called set in the common way and filled about half full of water, would fully answer the purpose. Steam at the temperature of boiling water, Mr. Smith thinks is best adapted to the purpose of steaming roots and other food for cattle. At this temperature, steam occupies about 1200 times the space of water; or one gallon of water reduced to steam of the same temperature with boiling water, will furnish 1200 gallons of steam. It is true that steam when it first begins to operate on roots and other cold raw substances must be somewhat rapidly condensed. But if the apparatus is tight, or if even a coarse thick cloth is thrown over the vessel in which the food is steamed, as recommended by the Complete Grazier, the whole will speedily become so much heated that the steam will be but slowly condensed, and of course the supply from the boiler need not be very copious. We cannot, therefore, see for what purpose connected with the steaming of any reasonable quantity of dry food for cattle, a boiler of 100 gallons capacity should be needed. In preparing liquid messes for cows giving milk, &c. by the agency of steam, its expenditure will be great, in consequence of its being condensed by contact with cold water. But that steam may be made a vehicle for conveying heat with very little waste by evaporation, has been proved by actual experiments. We shall cite one in this place. A letter from Mr. Robertson Buchanan, Civil Engineer, Glasgow, is published in *Tilloch's Philosophical Magazine*, vol. xxxviii, p. 76, from which the following is extracted. "A place of worship has been for a considerable time heated by steam on a most simple plan, so as to require little or no attendance, and does not require any water whatever to be added to that first put into the boiler, above three in a winter." We believe in this case the furnace and boiler were placed without the building which was heated by the steam, and the steam was conveyed by suitable tubes from the boiler into metallic vessels or reservoirs placed in the apartment which was warmed by its agency; and the tubes and reservoirs were so arranged that when any part of the steam became condensed it ran back into the boiler.

(Concluded in our next.)

SUMMARY OF CURRENT EVENTS.

A late arrival from Gibraltar has brought intelligence from Spain to the 11th of July. By this it should seem that things in that quarter wear a very menacing aspect. The population is divided into three parties, viz. The advocates for unmodified democracy—the sticklers for the old order of things, an absolute monarchy—and those who are friends to the present constitution, or a limited monarchy. On the return of the King from adjourning the Cortes, his carriage was beset by riotous assemblages, and his guards, being pelted with stones, fired on the assailants and compelled them to disperse.

The next day (July 1st) sanguinary scenes were anticipated, but nothing realized worse than menacing words and movements. But during the night four regiments of guards left their barracks, and encamped a league to the northward of Madrid. Many of their officers, and some privates, however, refused to accompany them, and joined a guard left in the Palace. The seceders, amounting it is said to about 4000, appointed a Frenchman (whose name is not mentioned) leader, and took the road to the French frontiers, avowing themselves to be friends to absolute monarchy. They were followed by Gen. Morillo, an officer faithful to the constitution and existing form of government, who attempted to persuade them to return to Madrid to protect the King, and perform their other incumbent duties. This they refused to do, and in their turn attempted, in vain, to seduce him from his allegiance.

The King remained at Madrid, to which tranquillity had been restored. He is considered as the leader of

the Constitutionists, and has been called upon to put himself at the head of the militia and march against the guards. This step, which would be the commencement of a civil war, he does not appear to be prepared to take.

The following (says the *Continental*) is an extract of a letter from a well-informed American gentleman in Gibraltar:—"Gibraltar, July 11. We have very serious accounts from Madrid. The Anti-constitutional party are taking measures to reinstate the old order of things—an unlimited monarchy, privileged clergy, &c. The country is in a state of anxious disquietude, and much blood is about to be shed in civil strife. Spain is in a wretchedly forlorn condition, and her capitalists are getting their property out of jeopardy. Nearly a million of dollars have been remitted to this place within a fortnight."

An article from Curacao, by the way of Norfolk, states that Gen. Bolivar had fought a battle with the Spanish General Cruz Mourgeon, on the borders of Upper Peru, which lasted all the day, and that Bolivar was compelled to retreat the next morning. The forces were stated to have been 5000 on each side; that the patriots lost half their army and one general; and that the loss of the Spaniards had been uncommonly severe.

Complaints (says the *Palladium*) are loud in England against the Bank, for not adopting some plan to render the counterfeiting of their bills more difficult, and the impositions and executions less frequent. Mr. Perkins' mode has been adopted by most of the private banks in England, and by the new Bank in Portugal.

A battle is said to have taken place between the Turks and Salots, which lasted three days, in which the Turks were defeated with the loss of 600 men taken, including fifty eminent Turks.

There seems to be no prospect of war between Russia and Turkey. On the contrary, a *Vienna Gazette* says, "We expect a declaration from the Emperor of Russia, by which he will detach himself from the Greek cause."

In France there have lately been some attempts to organize insurrections against the existing government. It does not appear, however, that they were successful.

A public dinner has been given at the city of London Tavern, to Don Francisco Zea, Vice President and Plenipotentiary of the Republic of Colombia.

The wheat harvest had commenced in England, previous to the date of the last intelligence, and is said to be very productive.

A great part of a late No. of the "Farmers' Journal," (an agricultural newspaper printed in London) is filled with details of Irish distress. A writer upon that subject observes that "beyond all doubt government will have to support the entire population of Ireland, before twelve months elapse, if it persist in refusing to allow a sufficient supply of legal tenders."

The author of *Waverley* is engaged in writing a new novel, to be called "Peveril of the Peake." It will be published in the autumn.

MARRIAGES.

In this city, Mr. George Bell, to Miss Mary Gardner. In Mantanzas, Mr. Michael S. Tracy, formerly of this city, to Miss Louisa Andrea, of M.

DEATHS.

In this city, Mrs. Therese Kenny, wife of Mr. Asa K. 47.—Mrs. Mary Forsaine, wife of Mr. Nath'l F. 45. Mr. William Todd, 75.—Mr. James Fenno, 62.—Charlotte H. daughter of Capt. Pardon Gifford, 15 months, killed by falling from a chamber window.—Mrs. Sarah L. Draper, wife of Mr. Edward D. 67.—Widow Lydia King, 77.—Mrs. Rachel, wife of Mr. Selim Haydon.—Widow Lydia Hunt, 69.—Mr. Horace Fairbanks, 27.—Emily, daughter of Mr. David Whiting, 2 yrs. 8 mo. In Taunton, Miss Augusta Thomas, 19, daughter of the late Mr. Isaiah T. Jr. of this city. In Mantanzas, Mr. Werham Priest, of Boston. Deaths in N. Y. last week, 102.—In Philadelphia 91.

ON THE LAWS OF A MISCHIEVOUS TONGUE.

BY T. C. FESSENDEN.

Many have fallen by the edge of the sword, but not so many as have fallen by the tongue.

Ecc. Apoc. xxviii. B.

Tho' millions the sword of the warrior has slaughter'd,
While fame has the homicide's eulogy rung;
Yet many more millions on millions are martyr'd—
Cut off by that cowardly weapon, the tongue.

One sword may be match'd by another as keen,
In battle the bold man a bolder may meet,
But the shaft of the slanderer, flying unseen
From the quiver of malice, brings ruin complete.

An insolent tongue, by a taunt or a gibe,
Enkindles heart-burnings and bloody affairs;
A treacherous tongue, when impell'd by a bribe,
The guiltless condemns, or a nation betrays.

A smooth subtle tongue vile seducers employ
The fair sex to lure to libidinous thrall;
A slip of the tongue may its owner destroy,
And the tongue of the serpent occasion'd the fall.

Then be it impress'd on Columbian youth,
That the tongue is an engine of terrible force;
Not govern'd by reason, not guided by truth,
A plague, which may desolate worlds in its course.

From the New York Statesman.

ON THE WILD INDIGO PLANT.

Messrs. Editors,

While we are anxiously copying the manipulations of European artists in our dye-houses, we are neglecting to use an indigenous plant, far more valuable than any thing contained or used in Europe. Our blue dyers began with the ash-vat, described by Berthollet, and others, and which Dr. Bancroft informs us, "is so costly, as to be chiefly employed to dye silk." If this were the only objection, it would in itself be sufficient to induce an alteration; but when in addition to this we know that the color is not so bright, or so permanent, as when indigo is fermented by some vegetable basis, containing in itself the primitive coloring matter, we shall be much surprised that this mode of dying has been so long continued.

The plant used by Europeans, from time immemorial, to ferment their blue vats, has been the isatis, or woad, which is indigenous in England and other parts of Europe. It is not surprising, therefore, that it should be used there, as nothing better offered itself; but in the U. States we have the wild indigo plant, growing abundantly every where, that possesses all the valuable fermentative properties of woad, with twenty times as much coloring matter, and giving a tint that for permanency and brilliancy is unrivalled.

It is well known, according to Mr. Clarkson, that the African dyes are superior to those of any other part of the globe.

The blue is so much more permanent and beautiful than that which is extracted from the same plant in other parts, that many have been led to doubt whether the African cloths brought into this country (England) were dyed with indigo or not. They apprehended that the colors in these, which became more beautiful upon washing, must have proceeded from another seed, or have been an extraction from other seeds which are celebrated for dying there—

The matter, however, has been clearly ascertained; a gentleman procured two or three of the balls, which had just been prepared by the Africans for use; he brought them home, and upon examination found them to be the leaves of indigo rolled up in a very simple state."

Having noticed the above article in Dr. Bancroft's incomparable work on permanent colors, I was induced last fall to collect some of the plant, not with an intention of coloring with it, as I had no means of preparing for that purpose, but to use the woad vats in place of swill from bran and madder, to assist their fermentation, which were weak, owing to the woad being of an inferior quality. I gathered nearly a cart load, too late in the season to obtain it in maturity, and had it boiled, and used the liquor when wanting. The plants were too old to retain much of those succulent juices in which their value chiefly consists, yet it answered the intended purpose, for the liquors so long as I was enabled to supply them with it, worked much freer and more vigorous, than in the usual way, and although this experiment was not decisive, for want of a sufficient quantity, and from the plant being too old when gathered, yet I am convinced by the effect produced that it may be used to great advantage.

As the indigofera is found every where in the United States, and in many places in great abundance, it would seem desirable that some experiments should be made on it, to test the superiority attributed to it, of which there appears but little room for doubt; for if this were established it would become an object of great national importance, inasmuch as the color made from it, would be superior to those obtained from Europe, and thereby give to American fabrics the preference in color in which they are now decidedly deficient.

I apprehend the balls are made by simply placing the leaves together, face ways, as they are gathered; that when a ball is made it ferments, and exudes sufficient moisture, to cause an adhesion of the mass; and that this process develops the coloring matter, so as to enable the vat liquor to extract it with sufficient facility. This is not the only mode of preparing the plant. The following extracts will prove there is considerable latitude, both in preparing and in working it afterwards.

Capt. G. Roberts, in the account of his voyages, mentions "the indigo plant as growing wild at Bonavista; and that the natives prepare it, only by pounding the leaves of the shrub while green, in a wooden mortar, with a wooden pestle, and so reduce it to a kind of pulp, which they form into thick round cakes, or balls, and drying it, keep it till they have occasion to use it for dying their clothes. Mr. Mungo Park, in the account of his travels in Africa, says, "that to dye cloth of a lasting blue color, according to the practice of the negro women, the leaves of the indigo when fresh gathered, are pounded in a wooden mortar, and mixed in a large earthen jar, with a strong ley of wood ashes, (chamberley being sometimes added) and the cloth is steeped in this mixture, and allowed to remain until it has acquired a proper shade. When indigo is most plentiful, they collect the leaves and dry them in the sun, and when they wish to use them, they reduce a sufficient quantity to powder, and mix it with ley as before mentioned.

Mr. Marsden, in his history of Sumatra, says, "the indigo shrub (Yaroom) is always found in their plantations; but the natives, to dye with it, leave the stalk and branches for some days in water to soak, then boil it, and with their hands, work some quick lime among it, with the leaves of the paco sabba for fixing the color. They then drain it off, and use it in a liquid state."

Other extracts might be added, confirming the good qualities of this plant, but I think enough has been made to convince the most incredulous reader, that it may be appropriated without much difficulty, to purposes highly valuable.

The indigo made from the wild plant is said to be of much better quality than that which is obtained from the cultivated, but that it does not contain so great a quantity of coloring matter.

The leaves should be gathered when the plant is in full blossom, which at three cents a pound, would be a lucrative employment for country children, and if a sufficient supply of the dried leaves could be obtained at that price, it might be rendered, when manufactured ready for use, at less than the first cost of woad in England. By this means the American dyers could be supplied with a native article now considered as useless, equal to woad as a fermentative medium, containing twenty times as much coloring matter, more permanent than manufactured indigo, and giving a color unequalled by any other plant, or process.

HOPSON.

Cleanliness.—Aristotle ranks cleanliness as a minor virtue; and Addison not only recommends it as a proof of refinement, and as the means of conciliating esteem, but considers it as having some analogy to purity of heart. To the opinions of these good judges in morals we may add, that it holds a place amongst the charms of social life, whilst it is, at the same time, the greatest preservative of health.

Value of Time.—The difference of rising every morning at six and eight o'clock, in the course of forty years, supposing a person to go to bed at the same time he otherwise would amount to 29,200 hours, or three years, 121 days, and 19 hours, which afford eight hours a day for exactly ten years, so that it is the same as if ten years of life, (a weighty consideration) were added, in which we may command eight hours every day, for the cultivation of our lives and the despatch of business.

It is a mortifying reflection, says Dr. Johnson, for any man to consider what he has done compared with what he might have done.

"Mr. P." said a citizen, "has a vast deal of wit." "Very probable," said another, "and he seems determined to keep his stock good for he never was known to expend or to make use of any."

Sir Thomas Overbury observes that the man who has nothing to boast of but his illustrious ancestors, resembles a potatoe—the only good belonging to him being under ground.

Dinner Time.—A person asked a Grecian philosopher what he thought was the proper time to dine. "Sir," said the ancient, "the proper time of dinner, with the opulent, is when they choose; with the poor man, when he can."

FOR THE NEW ENGLAND FARMER.

POINTS OF A HORSE.

MR. EDITOR,

A good horse is a desirable acquisition, and he who finds one, in the course of his life, may think himself lucky. The points, or marks, of a good horse, are perhaps not generally known, among your readers, though to many they may be familiar. A person who is well acquainted with the marks indicative of a good horse, is not very likely to be deceived in regard to his physical powers, though he may be, with respect to the character of the animal. A horse may possess all the points, or marks, characteristic of power, and at the same time, have some vice, that will render the use of him unpleasant, or dangerous. It is therefore advisable, before purchasing a horse, to give him a thorough trial, and in a variety of ways.

A particular quality, in a horse, is sometimes so desirable to the purchaser, that he is willing to dispense with many good points, for the sake of it. For instance, the difficulty and inconvenience of tying a horse, in the streets, are so great, that many gentlemen content themselves with indifferent horses, if they but possess the virtue of standing well. Very much may be known of a horse's character by his physiognomy; but to describe the different expressions of the human countenance is difficult, and the less definite ones of a horse, I shall not attempt—my object is merely to give some of the most prominent marks, or points of a good horse; a description of which may serve as a guide, in the selection of this useful animal. I begin with the head, which ought to be small and progressively to diminish in weight, and size, as it approaches the nose. The neck ought to be short and light. The head cannot be too small, nor the neck too short and light. The reason is obvious. The head and neck of the horse are placed wholly anterior to his points of support. The shorter the neck, therefore, and the lighter the head, the less likely is the horse to stumble and fall. The more weight there is anterior to the fore legs of a horse, the more difficult it is for him to keep his balance, or to recover himself on making a false step. This can be explained upon the principles of the lever, or by the steel-yards. Suppose a horse's neck ten feet long, and a head of a common size, attached to its extremity—the weight of the head, with this immense leverage, would be so great, that the weight of the body would not counterbalance it, and the horse would constantly be falling upon his nose.

A horse with a long neck is not only more likely to fall, but *ceteris paribus* his wind cannot be so good. The longer the neck, the more difficult is the access of air to the lungs. A horse, therefore, with a long neck, will have short wind; and is only calculated for slow draught. He will not answer for the turf. No horse can run well with a long neck.

The next point is the shoulder, several circumstances concerning which are important to be considered. The scapula or shoulder blade ought to be broad and long, and the muscles

attached to it thick and large. When the hand is passed down the neck and the shoulder blade cannot be felt, it amounts to a certainty that that horse has good action. The apparent thickness of the shoulder depends upon the obliquity of the shoulder blade, and in proportion as it is oblique, so is its motion limited.

The carcass of a horse ought to be a subject of particular attention. This cannot be too circular. A cylinder gives the greatest possible capacity. A horse, therefore, with a round chest, has more room for the expansion of his lungs than a horse with a chest otherwise formed. His wind must therefore be better; besides he fats much easier; he requires less food. A horse with a round chest will keep fat upon almost any thing, whereas it is almost impossible to fat a horse with a narrow or flat chest. A horse with a thin narrow chest cannot bear heat, has bad wind, is always lean, weak and tender.

The vigor of a horse depends more on the formation of the carcass than on any other point, and the reason must be obvious—the carcass contains the heart and all the important and vital organs.

The spine, or back, which extends from the fore to the hind quarters, cannot be too short for strength. A short, hump-back is indicative of great strength, especially in carrying weights. We arch bridges for the purpose of adding to their strength, and a horse's back may be compared to a bridge, and the four legs the four pillars of support. The shorter the arch, the greater weight it will support, and for the same reasons, a horse with a short, curved or hump-back (other things being equal) will carry the greatest burthen.

Although a short back is indicative of strength, it is not of speed and action. A long back must obviously give greater room for action. The Hare and Weasel have, in proportion to their size, extremely long backs; and "to run like a March Hare," is proverbial. A long back, however, must be a weak back, and unable to support heavy weights. In choosing a horse, therefore, for common use, it will be best that he should have a back of a medium length; neither too long nor too short.

The hind quarters of a horse ought to be long. I mean by hind quarters, the parts from the hanches backwards, the parts that lie between the *os Ilium* and the *os Ischium*.

The hock or gambrel ought to be long and broad. The *os calcis*, or heel bone of this joint, corresponds to the same bone in the human subject. The longer this bone is, and the further it projects backwards, by so much the greater length of lever, do the muscles act, which are attached to it. It must be obvious, therefore, that this is a very important point in a horse, and one that ought never to be overlooked. It is impossible to have a good horse, without a good hock. A horse may be a good animal with bad fore legs, but he never can be with a bad hock. The fore legs merely support the body—the hind legs propel it forward. The horse puts himself in motion and performs all his functions *solely* by the action of the mus-

cles attached to the *os calcis*. The further this bone projects backward, the longer is the lever by which the muscles act, and the greater will be their propelling power.

The legs of a horse ought to be flat—the bones small and the muscles large. Bones do not give strength, and when the bones of the leg are sufficiently large to support the weight of the animal, all over this is superfluous, and worse than superfluous; it is a dead weight upon his motions. Bones are mere levers, and the skeleton a mere frame, on which the muscles act. Bones are, in themselves, inert substances. Muscles give strength. All the motions of the animal are performed by his muscles. The relative position of the bones may be such as to add very much to the power of the muscles. When the bones are so placed with regard to each other, as to give a long leverage to the muscles, such muscles act with increased power; and in this consists, in a great degree, the excellency in the mechanism of the horse.

The above are the most prominent marks, or points, as they are called, of a good horse. In the purchase of a horse, however, many other circumstances are to be taken into consideration. It is of immense consequence that he should have perfect feet. It is obvious, that a horse with bad feet, however good his points may be, must be rather a useless animal. A horse with bad feet, is always an unsafe horse; he will always trip, and is very liable to fall. Any tenderness or uneasiness about a horse's feet, renders him unsafe. Even a shoe, that does not set easy, will surely cause a horse to trip.

The following description of perfect and imperfect feet, is taken from Goodwin's New System of shoeing horses—an Abridgment of which has recently been published in this city.

Perfect Hoofs.—"A perfect foot has the shape of a cone, except at the heel. The front, which comprises the largest portion of the wall or crust, is the most cone-like, and the quarters are less so. When the horse is standing on a pavement, the foot, at its base or bottom, is much larger than at the top or coronet, and the crust descends from the coronet to the bottom in a regular slope, at an angle of about 45 degrees in front."

"The hoof should be smooth and even on its surface, strong, tough and vigorous in its appearance; the heels should be well back, and the nearer they approach to the back part of the frog the better, and the more the quarters and heels approach to a perpendicular position, the more they are calculated to support the weight above: the space appropriated for the frog should be wide and open."

"Having described as much of a perfect foot as can be seen when the horse is standing, I proceed to describe the appearance and shape of a perfect hoof, when the foot is taken up. The first circumstance that deserves attention is the uniform box of horn, which being divest-

ed of all its superfluous or exuberant parts, approaches to the form of a circle."

"The words 'superfluous part' may require some explanation:—Suppose a horse to have run in the fields until he is four or five years old, and that his feet have never been touched by an instrument, this state of the feet, would by many persons, be called a state of nature, and the foot would therefore be thought perfect; but it ought to be considered like any other production of horn, which has grown into a state of exuberance in some part, and is worn and broken in others. When the hoof is divested of these exuberances in the same way, as we cut our nails to keep them in a fit state, I consider that the proper time to look at the hoof, to observe its natural shape. It will then appear that the base or bottom of the crust descends to the lowest part of the foot, and projects beyond the sole, and is that part which the horse rests upon. It should therefore be thick, firm and strong."

"As the crust is that part on which the shoe rests, and to which it is nailed, it is very important that it should be perfect in thickness and strength. The bars or binders, being a reflection or continuation of the crust, should be firm and strong, and should have an oblique position in the descent to their union with the bottom of the frog. The sole should also be firmly and uniformly united with the crust and bars, and be strong and concave."

"The frog, which is uneven in its surface, be-

ing convex on each side, concave in the centre for about half its length, and then convex to its termination, should be strong, full of horn, prominent and vigorous in its appearance, open in the centre or cleft, and full on its sides and points.

"The space between the frog and bars should be open, distinct, and clear, and the heels of the crust should come as far back, or nearly so, as the heel of the frog."

Weak Feet.—Feet of this description are frequently large, flat and thin, though there are also some which are very thin, but not out of proportion in size: both kinds are uniformly concave on the front part of the crust, and curl up at the toe, in proportion to the extent of the defect. It is equally observable, that the crust in feet of this description, is uneven on the surface; being frequently indented, wrinkled, and having a ringlike appearance."

Small Feet.—It is not unfrequent to see large horses, but chiefly among those which are thorough-bred, with small feet. The base of the feet of these horses not being broad enough to support the superincumbent weight, they are consequently insecure on their legs, and soon break down."

Large Feet.—"There is likewise a class of horses with feet of a form the reverse of the last described, having no particular malformation, but being too large and unwieldy."

"When such horses are required to work, the weight of the foot has a manifest effect on their action, rendering it slow and clumsy."

EXPLANATION OF THE CUTS.

FIG. 1.—Natural hoof, and representation of the French method of driving the nails within the crust, and going through a portion of the sole.

TUNISIAN SHEEP.

We have great pleasure in recording the following authentic history of an importation of Tunisian Sheep, and we particularly desire that our correspondents would furnish us with accounts, as detailed, respecting every importation of Live Stock, which has come within their knowledge; and especially, when the facts so conclusively demonstrate the tendency of agricultural pursuits and subjects to inspire all who embark therein, with a liberality of feeling and design which, so far from admitting the idea of venal rivalry or sordid monopoly, bid every one generously welcome to the fair enjoyment of new sources of profit.

Belmont, August 14, 1822.

DEAR SIR,

In your paper of the 2d instant, I see queries respecting the TUNIS BROADTAILED SHEEP. "How many were received? and were any sent into other states?"

I have given a full account of these sheep in the 2d volume of the *Philadelphia Agricultural Memoirs*. My opinions continue unaltered; and I had supposed the subject to have been exhausted. I have no desire to revive it, further than to answer your queries as fully as historical facts require; and that with no personal objects. I do not relate the circumstances to blazon my own exertions, but under a persuasion that a useful moral may be drawn from them. I am the only person acquainted with the whole subject, to which I do not mean to give more importance than your inquiries seem to elicit. Col. Pickering, with his accustomed candor, has published, in Poulson's paper of the 4th or 5th of July last, what he thought proper as to himself. The paragraph has not his signature; but he informed me of his having written it; and I mention it, for reasons operating with me.

I understood, from Gen. Eaton, and so did Col. Pickering, that eight or ten sheep were

shipped; but only a pair arrived. Being far preferable to the coast sheep, they were procured by Gen. Eaton, (as he informed me,) of the Dey's farm in the interior of the country, by the Dey's permission, as a compliment to the United States. It was therefore proper that they should pass under the direction of the Secretary of State. They arrived in the *Delaware*, in a public ship; and of course, were placed by Col. Pickering in the neighbourhood of the port of arrival. It would have been out of character with him, (only one pair having arrived) to have sent them into any other state; nor would he have so done, in whatsoever way he might have received them. I was informed that the rest of the shipment perished at sea. Capt. Gables, to whose care they were committed, had a character too respectable to permit any supposition that he was either negligent or selfish; yet Gen. Eaton expressed much dissatisfaction and chagrin.

The burthensome, though not regretted, deposit, was put into my hands by Col. Pickering. Considering myself as a kind of trustee; and always desirous of spreading through our country the benefits of such acquisitions; I refused offers of emolument; though no terms forbidding personal profit, were made. I gratuitously dispersed the breed, not only in Pennsylvania, but into the neighbouring states; at no small trouble and expense to myself. Several victuallers, finding the superiority of the mutton over that of all other sheep, both in quality and price, made up a purse and offered any sum I chose to fix for the Ram. I refused the proffer, and after his covering, during several seasons great numbers of ewes sent to my farm; and there pastured and served without charge; he was conveyed to my late friend, Gen. Hand's farm near Lancaster; where he was killed by dogs; after propagating the breed extensively. The ewe met the like fate, on my farm; having yeanned a healthy lamb at sixteen years of age.

Chancellor Livingston's sale of two Merino sheep for \$3000, gave impetus to the ardo which had begun to operate in favor of the breed. Had he given them away, the effect would have been far otherwise on the minds of both farmers and speculators. *Voilà les hommes*. Fancy paints profits in proportion to price paid. Small gains are counted on gifts, or cheap purchases.

Discovering the impolicy of continuing (how ever beneficial my distributions may, at first have been,) gratuitously to bestow lambs; and of my other modes of dispersing the breed without charge; I encouraged my neighbor, Thoma. Bones, in raising fine Broadtailed Sheep, from my stock, for sale on his own account. He did great justice to my confidence in him; and sold considerable numbers; many whereof at their request, I selected for the purchasers. Many were sent to South Carolina, as I mention in our volume. The credit of, and demand for the sheep were really enhanced by the prices paid for them, though those prices were moderate, indeed compared with those of Merinos; which overwhelmed the Tunisians in public opinion, during the Merino-fever.

Country people do not value an article given away; presuming that it is held by the donor in small estimation; and in this they are not singular. The usual short sighted practice among farmers, of selling to victuallers, or in the mar-

ket the best lambs and sheep; and keeping only those unsaleable; deteriorated the breed most lamentably. My tenants, who had the charge of my flock, had their share in this culpable propensity. Several butchers posted breeders from my stock, in *Jersey* and *Delaware*. The progeny were slaughtered for the market. This also diminished the multiplication of the breed. Yet I was surprised by the information I frequently received, at the numbers produced from an original pair, even under circumstances not always encouraging.

I know of no other importation of Barbary sheep, contemporaneous with the subjects of this account. Long after the arrival of the pair mentioned; I was informed that Capt. *Baron* had brought some *broadtailed coast* sheep into Virginia. But from the accounts of them I had heard, they were inferior to the Mountain sheep of *Tunis*; and so are all other African sheep which have fallen under my notice. The sheep of the Eastern countries, Asia and Africa, are generally (with some exceptions,) *broadtailed*.

Many years ago I saw, in England, in the King's flock at Richmond, several of the *Laticaudæ*. Some of them with cumbersome trailing tails, borne on little wheel carriages, dragged after them. None of them, in appearance, equal to the Tunis Mountain sheep. In my old, learned, and valuable work,—*Scheuchzer's Physica sacra*.—there are plates, admirably executed, of victims for the Jewish altars. Among them, trailing *Broadtails* similar to those I saw at Richmond. So that there are many varieties of the *Laticaudæ*; and the success of breeders entirely depends on the selection of the valuable kind.

The name, (as you seem to require it) I gave to the Ram, was *Caramelli*, that of the Ewe, *Selima*. They will, perhaps, become memorable, as the first emigrants to our country, from this branch of the extensive family of the *Laticaudæ*.

Not knowing, exactly, the object of your queries, I may have enlarged unnecessarily. But you may gather what you deem satisfactory, for any purpose you contemplate. Yours truly,

RICHARD PETERS.

JOHN S. SKINNER, Esq.

From the New England Palladium of Aug. 23.

RYE COFFEE.

Messrs. Editors,

A writer in the Palladium of the 16th inst. who signs a "Friend to Health," has advanced a theory on the effects of *Rye*, which appears so absurd, that I am almost inclined to think he meant the article as a *hoax*; be that as it may, the subject is of too much importance to the community to permit such unfounded assertions to pass without refutation. This writer attributes the cause of *weak limbs* and *debilitated systems*, which he says a vast number of persons have suffered from, to the use of "a compound of half *Rye*, and half imported Coffee, ground together;" and that "*Rye* is peculiarly calculated to produce that effect."—Now, if he had stated that a free use of the *spirit distilled* from *Rye* produced such effects, he might have found but few to controvert his position. But, that *Rye*, its *outer coat* or *bran*, by any preparation, except by distillation, is deleterious to *man* or *beast*, I pledge myself to prove to the satisfac-

tion of every unprejudiced person, is an assertion not founded on facts.

If the writer will apply to the able and worthy Professor of Chemistry at the University, he will learn, that most of this *outer coat*, which he says produces those debilitating effects, is, by the *roasting* process, converted into *carbon*—in plain English *charcoal*, which is *insoluble*, and of course, if the decoction is well fined, no part of it will be taken into the system, and if it was, no injury could possibly result, as a little charcoal is considered by most medical men as not unhealthy, and for some complaints is prescribed in large doses.

This "Friend to Health" admits that "a person may eat the *fine meal*, without witnessing any ill effects." Indeed! I will go farther, and say that it is a fact which can be fully substantiated, that five, or perhaps more, than ten millions of men that have composed the armies of *Russia*, *Sweden*, *Denmark*, *Prussia*, and the German Powers, during the wars of the last century, have subsisted upon little else than bread made with *Rye Bran*, and which they considered a luxury if the *bark of trees* was not mixed with it—for such compounds were often furnished by Peter the Great and Charles the 12th—yet history makes no mention of any complaint of "*weak limbs*, *debilitated systems*, or *uncommon inclination to sleep*," except what was caused by the innumerable *forced marches* those wretched beings were harassed with!

But this writer's theory is overthrown nearer home. The hardy yeomanry of Massachusetts eat very little other bread than *Rye*, coarsely *sifted*, mixed with Indian meal. The *outer coat* of *Rye* in our climate being very dry and brittle, is broken so fine in grinding, that a great portion passes through the *sieve* and is eaten.—Moreover, the lovers of *broken bread*, and I am one of them, well know, that the *finer* the *sieve* the less *sweet* the bread. But we have no complaint among our farmers of *weakness of limbs*, or that they are, like a parcel of *Turks*, under the influence of *opium*.

I presume that if the "Friend to Health" had ever been in *Market-street*, in the City of Philadelphia, he would not have introduced *Horses* to support his theory. He might there have seen fine teams of that noble animal, as large and powerful as Elephants, and as fat as Whales, just off a journey of 5 or 600 miles, across the Alleghany mountains, with a load of four or five tons, that were fed the whole route on *Rye*, *outer coat*, chaff and straw cut up together, and as much too as they wanted; without any other grain, or scarce a hock of hay during the whole journey! He happens to be equally unfortunate with the *Pigs* he has bro't forward to prove that *Rye Coffee* is injurious to the human system, for on this point I do speak from the experience of near thirty years, and from the use of more than a thousand bushels of *Rye* and *Rye bran* in rearing and fattening *Pigs*. This writer says that after eating bran they will "lie down and swell with weakness!" I have seen them lay down after being gorged with this nutritious food, and they might have appeared to the eyes of some persons to "*swell with weakness*," but I believe that it would appear on *dissection*, to have been caused by a full belly of this *poisonous* stuff, and their disposition to *sleep*, from its fattening properties! I could cite many examples to show the benefit

of feeding animals with *Rye* and *Rye bran*. But it is time to return to *Rye Coffee*, which appears to have been extensively used in the middle States, particularly in Pennsylvania, for several years past, but no accounts of its debilitating effects have reached us; on the contrary, I shall offer high *Medical* authority to prove that it is a strengthening beverage for the stomach. Gen. Calvin Jones, of North Carolina, one of the most eminent Physicians in the Southern States, and who stands in the front rank of the philanthropists of our country, has written a dissertation on *Dyspepsia*, the great prevalence of which he attributes, in some degree, to the use of strong imported Coffee, and he says that in order to induce some of his patients to dispense with it, he has prevailed on them to substitute *Rye Coffee*, and that the free use of it has relieved them!—A letter from him to Mr. Skinner on the subject, was published in the American Farmer, last March or April; it is not at hand now, or I would send it to you. I hope however to see it soon published in your valuable paper.

The goodness of Domestic Coffee depends on its being properly prepared from sound *Rye*. I look upon the discovery and introduction of it, as very fortunate and of great importance to the country, as it lessens the expense of a very considerable item in house keeping, and at the same time is conducive to health. Its use therefore should not be discouraged till some better proofs can be adduced of its ill effects, than vague surmises and arguments, drawn from *Horses* and *Swine*.

A MIDDLE-EX FARMER.

Mowing Match.—There was a famous mowing match in New Boston, on Saturday, August 17th, between Mr. Daniel Andrews, of New Boston, and Mr. Abel Hart, of Goffstown. The competition was who should mow an acre of meadow grass the quickest and best. The ground was staked out and the work performed in the presence of numerous spectators. Mr. Andrews completed his acre in one hour and twenty-six minutes. Mr. Hart, in one hour and twenty-eight and a half minutes. The victory was of course decided in favor of Mr. Andrews. *Amherst (N. H.) Cabinet*.

A safe, easy and cheap cure.—A broken winded horse had been kept in a field where there was not any water, except in the bottom of an old lime kiln, and had recovered his wind.—The owner ordered a stable shovel full of quick lime to be renewed every five or six days, and the water to be poured off, and a bucket of it to be given every day to a broken winded coach horse, aged eight years, which had almost a constant cough. The horse was supplied with water thus prepared for about five weeks, and kept in the stable. He is now perfectly recovered in his wind, and free from a cough.—*Conn. Journal*.

We have seen a twig broken from a pear tree (says the last Newburyport Herald,) this season, scarcely two feet long, which, when taken off, we are told contained upwards of 60 pears. On it was upwards of 60 hanging in clusters like grapes, and of a size as large as hen's eggs. It came from the town of Essex in this county.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.

MANURE.

It is a generally received opinion that in some soils of a loose texture, the fertilizing parts of manure escape by sinking beyond the reach of plants. The Hon. Timothy Pickering, in an Address to the Essex Agricultural Society, delivered May 5, 1818, made the following observations on this subject. Speaking of what is sometimes called *riddle land*, Mr. P. remarks:

"But is it true, that on such land, or on any land, the fertilizing parts of manure escape by sinking beyond the reach of plants? If they do, how happens it, that in lands which have been cultivated and manured for ages, every layer of earth below the cultivated soil is, nevertheless, found dead and barren? Is it not for this reason, that farmers in general cautiously avoid ploughing deeper than the soil, lest by stirring that dead earth, and mixing it with the soil, they should lessen its fertility? The result of a little experiment which I had made prior to our revolution then occurred to me. Its recital may in some other respects be useful.

"Within a stone's throw of my father's house, was a piece of sandy loam, which from its contiguity to the dwelling-place of himself and ancestors, for upwards of a hundred and thirty years, must have been kept, a large portion of that time, in tillage, and consequently have been often manured. Yet the colored soil was no more than five or six inches in depth. This soil I removed from one spot, with three or four inches of the earth next beneath it. Of the next, red earth, I then took up as much as measured a peck and a half. Dividing a long box into two equal portions by a board, into one I put a peck of the earth; and into the other a half peck, intimately mingled and incorporated with half a peck of clay—perfect clay to the touch; but it was taken from the edge of a clay-pit holding water, where cattle often drank, and a flock of geese bathed, during the summer. Hence the apparent clay was doubtless impregnated, in some degree, with the droppings from these animals. This box I placed, on the surface, in a garden. Adjacent to it, I sunk, to a level with the surface, a small earthen pot filled with the same sort of clay. In these three places I sowed turnip seed, as late as the 20th of August. In a few days I reduced the number of turnip plants in each to three. The pot of clay, even with the surface, received sufficient water from rains: but I regularly watered the parcels of earth in the box; bestowing equal quantities, and at the same times, on each division. Near the close of October, I carefully took up the turnips, and washed them, leaving upon them the fibrous roots and leaves. The three which had grown in the pot of clay weighed ten ounces—the bulbs hot to the taste, stringy and tough. The three from the dead red earth weighed only three ounces, and the bulbs were soft, spongy and insipid. But the three which had grown in the mingled red earth and clay weighed twenty-four ounces, and the bulbs were of good texture, and well flavored.

"From the facts above stated, I felt authorized to infer, that all the lost manure, (that is, all the parts not imbibed by the roots of plants, nor remaining in the soil) instead of *sinking* below the sphere of vegetation, *rose* into the atmosphere: and that "*riddle land*," (land on which

the effects of manure were not lasting) however highly manured, so soon lost its fertility, not by letting the essence of the manure *sink* speedily through it, but by its *incapacity to retain it against the power of evaporation.*"

From these, and other considerations, Mr. Pickering infers, "that manure arising from dung, and from all animal and vegetable substances, should be exposed as little as possible to the sun, the air and washing rains, and when applied to the soil, be immediately ploughed in. And further that the aim of the husbandman, possessing a soil from which the essence of his manure soon escapes, should be to add something which will render it more tenacious; like the soil which, in current language, is said 'to hold manure well.' For this purpose, nothing, probably, is equal to clay."

LIVE STOCK.

In observing on premiums given by Agricultural Societies for the best animals, Mr. Pickering observes:

"With great deference I would inquire, whether giving rewards for the *biggest* and the *fattest*, is the best mode of obtaining the *most valuable* breeds? Bakewell, the English celebrated breeder of cattle, sheep and swine, exercised his genius to produce such as were excellent in form, of sufficient size, which yielded the greatest quantity of meat on the most valuable joints, and would grow and fatten on the smallest quantities of food. In the fattening of cattle and sheep, there is a point to be attained, at which their flesh will be of the best quality, and most valuable to the consumer. Is not all beyond this a waste of time and expense in their keeping?"

INDIAN CORN.

Under this head Mr. Pickering remarks:—"The improving of our husbandry, in New England, is to be expected, not from a rejection of Indian corn as the ruin of our lands, but by a better management of that crop, in order to render it, as it appears it may be rendered, the best preparation for a crop of wheat, and other small grain.

"Every farmer knows how eagerly cattle devour the entire plant of Indian corn in its green state; and land in good condition will produce heavy crops of it. Some years ago, just when the ears were in the milk, I cut close to the ground the plants growing on a measured space, equal, as I judged, to the average product of the whole piece; and found that, at the same rate, an acre would yield twelve tons of green fodder; probably a richer and more nourishing food than any other known to the husbandman. And this quantity was the growth of less than four months. The ground was rich, and yielded, at harvest, upwards of fifty bushels of corn to the acre. The green stalks of our northern corn are incomparably sweeter than those of the southern states; at least when both sorts are grown in the north. Perhaps the greater and longer continued heats of the south may give a richness to the same large plants, which these cannot attain in the north. The stalks I have grown, rose to the height of 13 or 11 feet, and many of them weighed above five pounds. To support this height they are necessarily thick and woody in their fibres. My cows ate a small part of them

—reluctantly—while they would devour the stalks of our northern corn. It has appeared to me that the sort called *sweet corn*, (having a white shrivelled grain when ripe) yields stalks of richer juice than the common yellow corn. It is also more disposed to multiply suckers—an additional recommendation of it, when planted to be cut in its green state, for horses and cattle, and especially for milch cows; and its time of planting may be so regulated as to furnish a supply of food, just when the common pastures usually fail. I am inclined to doubt whether any other green food will afford butter of equal excellence."

FALLOW CROPS.

Mr. Pickering further observes, that, "The substituting of fallow-crops for naked fallows is one of the capital improvements in English husbandry. The naked fallows, formerly in universal practice, consisted in repeatedly plowing the land from spring to autumn—with two objects in view: one, the destruction of weeds, with which their lands became foul by repeatedly cropping them with small grain, as wheat, barley, oats, rye, in immediate succession; for the weeds springing up with these crops, and ripening their seeds, the soil, in three or four years, was so amply stocked, that some mode of extirpating the weeds became indispensable. But for many ages no other than naked fallows seem to have occurred. The English farmers now grow fallow crops, selected according to the nature of their soils; as beans, carrots, turnips, potatoes, mangel wurtzel, cabbages. While these are growing, they *fallow* the ground; that is, they stir it repeatedly with the plough or hoe, or both; by which they as effectually destroy the weeds as by the naked fallow; and at the same time benefit their crops, whose products reward them for their labor.

"Naked fallows seem also formerly to have been considered as the means of *enriching* as well as of *cleaning* the land. The error of their practice, in this view, cannot be better illustrated than by the following fact, communicated above 30 years ago to the Philadelphia Society of Agriculture, when I was a resident member, and which I well recollect. But to prevent circumstantial errors in the recital, I have turned to the Notes on Husbandry, by Mr. Bordley, (who was the vice-president of the society,) where the case is stated.

"A gentleman of Maryland (Mr. Singleton of Talbot) ploughed up part (and this was the richest part) of a clover field, in March, intending to plant it with tobacco. It happened, that the tobacco crop was omitted. So, this part was *fallowed*, that is, it was repeatedly ploughed in the summer, and on the first of September, sown with wheat. The residue of the clover field was twice mown. In August it was *once* ploughed, and on the same first of September sown with wheat. At harvest, the fallowed part of the field yielded only 11 and a half bushels to the acre. The other part, besides two crops of clover hay the preceding year, now gave 21 and a half bushels to the acre. This striking fact admits of an easy explanation, and in conformity with the principles already advanced. The repeated ploughing of the fallowed part of the field exposed the clover plants, roots and tops to the sun and air, by which they were dried up, and nearly annihilated; while other vegetable food in the

soil was also dissipated, or greatly reduced, by evaporation. But the clover, turned under by a single ploughing, was completely covered with earth, kept moist, gradually rotted, and so supplied food to the wheat plants most plentifully when most wanted, that is, in the ensuing season, when the wheat was attaining its complete growth, and ripening the grain."

IMPROVEMENT OF SOILS.

Soils may be improved by the admixture of earths to alter their texture. This is a distinct thing from applying the substances commonly called manures. A soil may be composed of materials so essentially unfriendly to vegetation that any attempt to manure it without altering its constitution, or correcting its noxious qualities, would be like feeding a sick man with nourishing things, without removing the cause of his disorder.

Sir John Sinclair says, "Soils with acids, or salts of iron, may be ameliorated by the application of earthy lime or chalk. The sulphate of iron (copperas) is thus converted into manure. If there be an excess of calcareous matter (lime or chalk,) it may be improved by the application of sand or clay, or earthy substances. Soil too abundant in sand, are benefitted by the use of clay, or marl, or vegetable matter. A deficiency of vegetable or animal matter must be supplied by manure. An excess of vegetable matter is to be removed by burning, or to be remedied by the application of earthy materials. The substances necessary for improving soils are seldom far distant. Coarse sand is often found immediately upon chalk, and perhaps always under it, while beds of sand and gravel are commonly below clay, and clay and marl generally below sand."

PRESERVING MEATS.

The following recipes are from Additions to Willich's Domestic Encyclopedia, by Thomas Cooper, Esq. Professor of Chemistry and Mineralogy.

"If meat be intended merely for family use, and to be used in two or three months, the following pickle deserves to be recommended: Water, one gallon; salt, nineteen ounces; salt petre, one ounce and a half; sugar, half pound.

"The Russians are fond of the flavor of juniper berries, and add a pound of bruised juniper to a gallon of pickle.

"A tea-spoonful or two of cayenne pepper to the gallon, greatly increases the preserving power of the pickle.

"To cure gammons, first sprinkle them as soon as they are cut and trimmed, with a little (Liverpool) salt. Let them lay together for twelve hours: take them out of the tub, drain and wipe them; then rub them separately with a mixture of twelve parts common salt and one part salt petre, well dried and then ground fine. Rub in this mixture well; lay them in the pickling tub, and the next day rub them again with a similar mixture. The day after fill up the tub with a brine made in the proportion of 18 oz. salt, 1 lb. molasses, and 1 oz. salt petre, to the gallon of water. In this pickle they may stay for a fortnight. Then take them out, drain, wipe and smoke them.

"If they are suffered to make their own brine by means of dry salt and salt petre entirely, they will lose too much of the juices of the meat, and become hard and dry

"I have successfully cured beef in summer thus:

"I killed an ox in the middle of August, at 9 o'clock in the evening; it was cut up at 3 o'clock in the morning. The pieces were quickly rubbed with a mixture of ten parts of salt, and one part of salt petre, and put into a barrel. In the mean time a brine composed of 1 1-2 lbs. of salt, 2 oz. of salt petre, and half an ounce of common pepper, to the gallon of water, was ready over the fire, and when the beef was all packed in the barrel, it was poured on boiling hot. This prevented and destroyed all fly-blows. In a week, the pieces were taken out, drained and wiped; the pickle was boiled over again, scummed, and again poured boiling hot on the meat when re-packed. The process answered the purpose perfectly."

A METHOD OF PRESERVING CREAM.

Take twelve ounces of white sugar, and as many grains of finely powdered magnesia, and dissolve them in a small quantity of water, over a moderate fire. After the solution has taken place, 12 oz. of new cream should be immediately added, and the whole uniformly mixed while hot. Let it then gradually cool, and pour it into a bottle, which must be carefully corked. If kept in a cool place, and not exposed to the air, it may be preserved in a sweet state for several weeks, and even months.

Domestic Encyclopedia.

TO PREVENT BOTTLED CIDER FROM BURSTING.

Make a strong frame of plank, say 1 1-2 or 2 inches thick and 9 deep, by locking it together edge-wise, place it in the cellar, and sit the bottles of cider in it, (after being well corked) as close as possible, until it is entirely filled, except the space for one bottle, which must be left to commence taking them from, when wanted for use. Then put clean sand on them, and settle it between the bottles, by throwing on alternately water and sand, until the sand is well settled half way up the neck of the bottles. In that situation the bottles will be preserved, filled with the very best cider for any length of time.

By placing ice on the sand over the quantity of bottles proposed to be used a day, it will be as if put into ice water.—*American Farmer.*

TO PREVENT SKIPPERS IN BACON.

Take of red pepper finely powdered one table spoonful for every joint of meat, and rub it on the meat with the salt, when it is first cut up. It has been often tried, and was never known to fail in producing the above effect.—*ib.*

EXTIRPATING RATS AND MICE.

Lay bird lime in their haunts; for though they are nasty enough in other respects, yet being very curious of their fur, if it is but daubed with this stuff, it is so troublesome to them, that they will even scratch their skins from off their own backs to get it off; and will never abide in the place where they have suffered in this manner.—*Farmer's Journal.*

Quere.—Would tar answer the same purpose as bird lime?

From the Providence Journal.

To those who make, and those who love good Cider.

A few years ago, I was dining with a friend, who knew my fondness for cider with my food.

He remarked, "my friend, I have no cider to offer you. Our apples have been principally cut off by frosts and insects, for several years past; but I can give you some cider wine." I took some of it, and diluted it with water, sufficient as I calculated, to reduce it to the strength of late made cider. When I drank of it, to my surprise, I found I had a glass of very excellent cider, with only the taste of a little apple brandy in it. The discovery of this fact suggested to my mind the following conclusion:—That farmers in a plentiful year of apples, may, with a little care, lay up a supply of good cider, against a year of scarcity. This may be done within a small compass, in the following manner:—Take your first made cider, which is fit only for the still, and convert it into brandy; put nine gallons of this brandy into a new barrel; then fill the barrel with late made cider, well strained, and bung it tight. This gives you the strength of near four barrels of cider, in one. The strength given to it by the brandy, will preserve its sweetness entire, for many years. That which I drank was ten or twelve years old; and it was not impaired by age. When it is used, it only requires a sufficient quantity of water mixed with it, to render it excellent cider. The barrels should be new, and clean. To guard against the rotting which is caused by damp cellars, they should be iron bound, and well painted. In this manner, any farmer, who has the fruit, may put up, in six barrels, the essence of twenty barrels of good cider, and keep it until a time of need. It will *fine* itself; and will grow better with an increase of age. Besides, if it is not wanted as cider, it is a very pleasant cordial, when *undiluted*; and, with the addition of a bushel of wild grapes, bruised, and put into each barrel, it imbibes the peculiar flavor of the grape, and becomes a very pleasant wine.

As there is an unusual quantity of apples this year, I have thought this communication might be useful to agriculturists. Now is the time for grinding up the early windfalls; and the cider, which these produce, if distilled, will furnish the brandy necessary for making the cider wine. And I can assure you, my friends, prepared in this way, it is much pleasanter, and less injurious to health and morals, than when drunk, in the usual manner, mixed with water.

Those farmers who are fond of good cider with their food, and who have felt the want of it, in consequence of a scarcity of apples, will, I trust, feel the importance of attending to this subject, now, when they are blessed with an abundance of fruit. And another season, when their neighbors are destitute, the possession of a plenty of excellent cider in their cellars, will more fully realize to them the value of this communication, if they will make the experiment.

A. B.

A correspondent states that the medical qualities of pulverized Charcoal, are daily developing themselves. In addition to its value in *bilious* disorders, two ounces of the Charcoal boiled in a pint of fresh milk, may be taken in doses of a wine glass full, by adults, every two hours, in the most obstinate *dysentery*, until relief is imparted, which has not failed to be the effect in almost every instance. It is harmless and the experiment may be safely tried. Charcoal made from maple wood is the purest that can be readily obtained.—*Baltimore Chronicle.*

From the Floridian.

NATIVE NUT GALLS.

Messrs. Editors,

It may perhaps be gratifying to your readers to learn, that among the abundant vegetable productions of West Florida, the *Quercus Cerris* or Oriental Oak stands in the first class. It owes its importance principally to the production of Nut Galls. They have hitherto been imported from the Mediterranean at a great expense, and their importance in manufactures is well known. They are the production of an insect of an *hymenopterous* species. The *Cynips Quercifida*, who deposit their eggs on the leaves and tender branches of the tree; an excrescence is soon formed around the egg, which enlarges to a ball the size of a bullet, enclosing the egg; which in process of time is hatched, and the embryo often undergoing several changes, finally eats its way out of its prison. This excrescence is the Nut Gall; and those found in Florida are equal in every respect to those imported from the Levant.

This tree seldom attains the height of ten feet, and grows principally in low and wet situations, and the galls cover the branches in great profusion. The writer of this gathered in the space of a few moments several pounds. When it is taken into consideration the importance of this production in Dying and Medicine, their present high price (from 50 to \$60 per cwt.) and their not being indigenous in any other part of the U. S. we know of nothing that would so well repay the enterprize of any of our citizens, as collecting and sending them to the northward for sale.

A Friend to Domestic Industry.

From the Amherst (N. H.) Cabinet.

The Committee of the Hillsborough Agricultural Society appointed to view the field products of competitors, performed the duty assigned them in the present week, agreeably to the new regulation of the Society, substituted in the place of the greatest crops, viz. "The premiums are to be awarded by a viewing committee from actual inspection of the crops growing in the fields, and they will take into consideration not only the crops, but the soil, situation, former and present method and expense of culture, and the general husbandry of the farm." The gentlemen composing the committee who attended to the duty of their appointment, were Rev. H. Moore, P. Woodbury, Esq. Capt. Wm. Riddle, Capt. E. Abbot, Joseph Cochran, Esq. Mr. Phillip Brown, and Mr. Porter Kimball. This committee appears to have been judiciously chosen; being all men of practical farming knowledge. They passed through this and the neighboring towns on Wednesday, and were accompanied by a number of gentlemen in viewing the farms entered for competition. They proceeded in their business with precision and expedition, and evinced judgment and skill suited to the undertaking. The committee expressed themselves highly pleased with their employment, and the highest encomiums on the reception and generous treatment they every where met with on their tour of observation—the people generally appearing greatly pleased with the change of the system of granting premiums on agricultural products. The committee entertain no doubt that premiums awarded in this manner will produce the happiest results. It is hoped that this ex-

periment will excite the farmers of the county to a lively sense of the importance of promoting the general interests of the Society as immediately connected with their own and the general welfare of the community—That hereafter the Society may be enabled to offer premiums for the best managed farms, taking into consideration the soil and situation, the ability of the owner to make improvements, and the system on which he manages—and that the competitors may be greatly increased.

NEW ENGLAND FARMER.

BOSTON:—SATURDAY, AUGUST 31, 1822.

We would beg leave to direct the attention of our readers to the piece with which this day's paper commences, which we think rational, philosophical, and calculated to be useful. Future favors of a similar nature from the same hand are respectfully solicited.

COOKING FOOD FOR CATTLE.

(Concluded from page 31.)

In the construction and management of "root steamers," (as they are called by the Complete Grazier,) there are some things worth attention, which we have yet to notice. "If water be heated in a close vessel no steam will be formed; if the steam escape by a small hole there will be less formed than if the whole surface of the water were uncovered."* It follows that, other things being equal, shallow vessels, or vessels about half full, exposing large surfaces of the water in proportion to its quantity, from which the steam may ascend, will afford the most steam with a given quantity of heat applied.

Allowing that one gallon of water will produce 1200 gallons of steam, it would be easy to calculate the exact quantity of water necessary to boil in order to fill with steam the vessels in which the food is cooked, were it not that the following circumstances are to be taken into consideration. Steam will be condensed with greater or less rapidity in proportion to the temperature of the atmosphere, and the temperature, the solidity, the dryness or wetness of the feed which it operates upon. Besides if the whole apparatus is made perfectly tight, a *safety valve* will become necessary, through which some of the steam will make its escape; and the exact quantity of the fugitive steam cannot be calculated. If the vessel in which the food is prepared is either open at top (as is common when a fire pail kettle and a hoghead placed over it is used,) or is covered only by a thick coarse cloth (as recommended by the Complete Grazier,) a considerable quantity of steam will be wasted. But though, perhaps, no precise data can be given for generating or graduating the exact quantity of steam necessary for given purposes, as relates to cooking food for cattle, we believe there is commonly more water boiled, and of course more fuel used in steaming *solid* food than is necessary. Accurate experiments on this subject, and their results carefully recorded, would undoubtedly prove us full.

Steam may likewise be very profitably used in preparing *liqua* messes for cattle, as well as in warming vats for dyers, tanners, paper-makers, &c. &c. Many attempts have been made to heat liquids by steam introduced into them, which have generally failed, in consequence of its not being known, or not adverted to by those who have attempted the process, that fluids are *non-conductors of heat*, and consequently that heat cannot be made to *descend* in them. It is therefore necessary that the tube, which conveys the hot steam,

should open into the *lowest part* of the vessel, which contains the liquid to be heated. We shall abridge from Count Rumford's Essays such directions as will enable any workman of ordinary sagacity to effect this purpose.

To succeed in heating liquids by steam, it is necessary, not only that the steam should enter the liquid at the bottom of the vessel which contains it, but also that it should enter *coming from above*. The steam tube should be in a vertical position, and the steam should *descend* through it previous to its entering the vessel, and mixing with the liquid which it is to heat; otherwise this liquid will be in danger of being forced back into the boiler by this opening; for the hot steam being suddenly condensed on coming into contact with the cold liquid, a vacuum will necessarily be formed in the end of the tube; into which vacuum, the liquid in the vessel, pressed by the whole weight of the incumbent atmosphere, will rush with great force, and with a loud noise; but if this tube be placed in a vertical position, and if it be made to rise to the height of six or seven feet, the liquid, which is thus forced into its lower end will not have time to rise to that height before it is met by steam and obliged to return back into the vessel. There will be no difficulty in arranging the apparatus in such a manner as effectually to prevent the liquid to be heated from being forced back into the steam-boiler; and when this is done, and some other necessary precautions to prevent accidents are taken, steam may be employed with great advantage for heating liquids; and for keeping them hot, in a variety of cases, in which fire, applied immediately to the bottoms of the containing vessels is now used. The boilers intended to be heated in this manner may be placed in any part of a room, at any distance from the fire, and in situations in which they may be approached freely on every side. They may be surrounded with wood, or constructed entirely with wood. The tubes by which the steam is brought from the principal boiler (which tubes may be conveniently so pended just below the ceiling of the room) may in like manner, be covered, so as almost entirely to prevent all loss of heat by the surfaces of them; and this to whatever distance they may be made to extend.

In suspending these steam tubes, care must, however, be taken to lay them in a situation *not perfectly horizontal* under the ceiling, but to incline them a small angle, making them rise gradually from their junction with the top of a large vertical steam-tube, connecting them with the steam boiler, quite to their furthest extremities; for, when these tubes are so placed, it is evident that all the water formed in them, in consequence of the condensation of the steam in its passage through them, will run backwards, and fall into the boiler, instead of accumulating in them, and obstructing the passage of the steam, which it would not fail to do were there any considerable bends or windings, upwards and downwards, in these tubes, or of running forward and descending with steam into the vessels containing the liquids to be heated, which would happen if the tubes inclined *downwards*, instead of inclining upwards, as they recede from the boiler.

The steam tube may either descend within the vessel to which it belongs or on the outside of it, as shall be found most convenient. If it comes down on the outside of the vessel, it must enter it at its bottom, by a short horizontal bend; and its junction with the bottom of the vessel must be well secured to prevent leakage.

When several steam tubes, belonging to different containing vessels, are connected with the same horizontal steam conductor, the upper end of each of these tubes, instead of being simply attached by soldering

* Nicholson's Chemistry

to the under side of the conductor, must enter at least one inch within the cavity of it; otherwise the water, resulting from a condensation of a part of the steam, in the conductor by the cold air which surrounds it, instead of finding its way back into the steam boiler, will descend through the steam tubes, and mix with the liquids in the vessels below; but when the open ends of these tubes project upwards within the steam conductor, though it be but to a small height above the level of its under side, it is evident that this accident cannot happen. In order that the ends of the steam tubes may project upwards within the horizontal conductor, the diameters of the former must be considerably less than the diameter of the latter.

As it is essential that the steam employed in heating liquids, in the manner before described, should enter the containing vessel at, or very near its bottom, it is evident that this steam must be sufficiently strong or elastic to overcome, not only the pressure of the atmosphere, but also the additional pressure of the superincumbent liquid in the vessel; the steam boiler, must, therefore, be made strong enough to confine the steam, when its elasticity is so much increased by means of additional heat, as to enable it to overcome that resistance. This increase of the elastic force of the steam need not, however, in any case, exceed a pressure of five or six pounds upon a square inch of the boiler, or one third part, or one half, of an atmosphere.

In this and in all other cases, where steam is used as a vehicle for conveying heat from one place to another it is indispensably necessary to provide safety valves of two kinds; the one for letting a part of the steam escape, when, on the fire being suddenly increased, the steam becomes so strong as to expose the boiler to the danger of being burst by it;—the other for admitting air into the boiler, when, in consequence of the diminution of the heat, the steam in the boiler is condensed, and a vacuum is formed in it; and when, without this valve there would be danger, either of having the sides of the boiler crushed, and forced inwards by the pressure of the atmosphere, or of having the liquid in the containing vessels forced upwards into the horizontal steam conductors, and from thence into the steam boiler.

Count Rumford proceeds to shew that the principles above described had been carried into effect upon a very large scale, by Messrs. Gott and Company, at Leeds.

The dyeing house of Messrs. Gott and Company is very spacious, and contains a great number of coppers of different sizes, some of which contain upward of 1800 gallons, and they are all heated by steam from one steam boiler. One of the largest of these coppers, containing upwards of 1800 gallons, when filled with cold water from the cistern, requires no more than half an hour to heat it till it actually boils! By the greatest fire that could be made under such a copper, with coals, it would hardly be possible to make it boil in less than an hour. Common wooden tubs may be substituted for coppers, for retaining vessels, or vessels in which the food is cooked.

The foregoing may give our readers some idea of the mode of heating liquids by steam. Those, however, who would wish to construct an apparatus for boiling liquids by steam, would do well to consult Count Rumford's Essays, which may be found in the Boston Athenæum.

We would here observe that what we have recommended and in part described in this essay does not rest on theory, nor speculations not tested and warranted by actual and beneficial practice. This we endeavored to shew in the beginning of our essay. (p. 23) and to make it still more evident, we shall add to this

article a few facts derived chiefly from Mr. Smith's Address to the Maryland Agricultural Society.

Mr. William Bean, of the city of Baltimore, the constructor of my apparatus, has stated to me that he can build such as mine at a cost from 60 to 100 dollars. A boiler of the lowest price, containing 30 gallons, would be sufficient to cook food for the stock of most farms in our country. The capacity of my boiler is 180 gallons. It has enabled my people for some time to cook every day, for more than one hundred head of stock, nourishing food, consisting of cut hay or straw, or corn tops and blades, or corn husks mixed with meal produced from the corn and cob ground together, or with other meal and a due proportion of water. When this food is intended for cows in milk, as much water is used as will serve to give it the liquid consistency of what is called a wash; but when it is prepared for dry cattle or for horses, so much water only is applied as is used in the common feed of chopped rye and cut straw.

Clover hay, corn tops, blades and husks, when steamed, have been found greatly to contribute in the winter season to the improvement of the quality of the milk, inasmuch as, in a great degree, to impart to the butter the yellow color and delicate flavor, it would have received from the same articles in a green state. It is, however, proper to premise, that to produce these pleasing effects, the clover hay and the corn fodder must be well cured. When cut straw has been used, the advantages, though very perceptible, have not, from the dryness of the straw, been so strongly communicated to the butter. If the steamed food should not be intended for cows in milk, or for cattle for the butchers, or for working oxen or horses, but for stock going at large, there is no necessity to mix it with any meal whatever. And from the experience I have had I have no hesitation in pronouncing that not only straw and corn fodder, but the very corn stalks, instead of "wasting their sweets on the desert air," may, if well cured and preserved, be converted into nourishing food for the maintenance of stock throughout the whole winter season.

The richness of the milk, the flavor and yellow color of the butter, afford the most convincing evidence of the excellency of cooked food. And this is confirmed by experiments made from time to time, in suspending and resuming the steamed preparations. Besides, under this system, every particle of the hay, of the straw, and of the coarsest offal is consumed. There is no waste; every thing is eaten with avidity. It would hence appear that the steaming apparatus, converting as it does all vegetable matter whatever, coarse as well as fine, into the greatest quantity of nutriment, affords the united benefits of nutrition and economy. And in this country, where so little green food is raised for the maintenance of cattle in the winter, the steaming of straw and corn fodder combines incalculable advantages. Besides, it should ever be kept in mind that, in the feeding of animals, the provender ought to have bulk as well as nutriment. A certain distention of the stomach is requisite.

NEWS FROM EUROPE.

London papers to the 15th July have been received by the Herald, Capt. Fox, from Liverpool. By these it appears that Madrid was in extreme agitation from the 1st to the 5th of July. On the 6th at night, one of the battalions of the revolted troops made a forcible entry into the city. They entered the avenues leading to the square at day light, and commenced a vigorous fire on the constitutional troops, or militia. The latter defended themselves successfully. At six in the morning, Gen. Morillo ordered a piece of artillery to be placed in the main street to prevent the retreat of the guards in that direction, the militia continued to fire upon them, and the mutineers, being repulsed on every side, withdrew to the palace, where they were received and welcomed by some persons of rank. They then offered to enter into negotiations, but notwithstanding their offer, subsequently attacked some of the militia, but were again repulsed. Some other events took place, whose details are of little importance. On the 8th, all the remaining mutineers surrendered, and the Bishop, in presence of the militia, performed a solemn mass in honor of the triumph.

A Paris paper of the 15th ult. states that "a meeting of the Foreign Ministers has been held at Madrid,

to sign a declaration relative to the events in that capital. Mr. Forsyth, the American minister, refused to sign it, as totally untrue; asserting that the loyal adherents to Ferdinand were his greatest enemies, and that the Cortes, Legos, &c. were his best friends. It is added that eventually all the foreign ministers, except the Austrian, agreed with Mr. Forsyth.

LONDON, July 19.—*Importance*.—Extract of a private letter received this morning from Paris, dated Monday evening last:—"The French government have just concluded a contract for 10,000 horses for the artillery, &c. All the different officers have been ordered to their posts, and the conscripts of the year 1821 are ordered to join the army. If this does not look like war, I don't know what does."

Mormon.—The British Missionary Society in London have published an official account of the arrival of a *Mormon*, at the Cape of Good Hope, and given a full description of her, and state that the proprietor of the extraordinary animal is Capt. Peden, of Boston, in America; who had been offered 10,000 dollars for it, but refused to part with it for any sum.

STILL LATENT.—Since writing the above, London papers have been received by an arrival at this port, as late as the 25th ult. Accounts from Madrid are to July 12. The insurrection of the Guards is entirely suppressed—the late minister of war deprived of his functions. Disturbances, however, continue to exist in some of the Northern provinces of Spain. It was said that the Constitutionals had gained a victory in Catalonia. The insurgents fled to the mountains, where large bodies of them collect, and make occasional predatory descents on the neighboring cities.

A petition has been presented to the British Parliament from certain persons in Leeds, praying for the interference of the House in the massacres of the Greeks by the Turks. The petition was ordered to be printed.

HARVARD UNIVERSITY.

The annual commencement at this ancient seminary took place on Wednesday. His Excellency the Governor, with the other State Authorities, was escorted from this city to Cambridge, in the morning, by the corps of Cavalry under Capt. Richardson. A procession was then formed, consisting of the Government of the University, and their invited guests, which proceeded to the meeting-house, where the literary exercises commenced at half past ten o'clock, to a very crowded and discriminating audience. Among other distinguished persons, we were gratified to see the Rev. President Holley, of the Transylvania College, of the audience on this interesting occasion. After the usual exercises, the Government, with their guests, the Alumni of this and other similar institutions, repaired to the Hall, partook of a generous repast, and concluded the day with their accustomed festivity.

The degree of A. B. was conferred on fifty-nine young gentlemen.—*Gazette*.

NEW YORK, August 27.

Although the last reports of the Board of Health are not of a nature to create new alarm, yet the panic still continues, and is extending in the lower part of the city. This is however, natural. The alarm is more contagious than the fever; the stoutest heart is appalled by seeing his neighbors fleeing from their abodes, and the only relief is to follow them. Broadway, and the other great Avenues to the upper part of the town and Greenwich, exhibited yesterday a continued throng of carts, laden with merchandize from the warehouses below. It has already become a scene of bustle and business at the new locations.

The Banks began to move yesterday morning, and we understand, are all now established at Greenwich and Broadway, excepting the Manhattan, which is at their building in the Bowery, near the junction of Broadway. This is a great calamity to New York, but it is hoped, will be borne with fortitude.

On the 24th inst. the President issued his Proclamation opening the ports of the United States to British vessels from ALL the British Colonial Ports at which our vessels are admitted—and on reciprocal conditions, as regards the vessels, proportion of mariners, and nature of the cargo.—*Palladium*.

FOR THE NEW ENGLAND FARMER.

THE RICH MAN AND THE POOR BOY.

A certain lad, who was a wag complete
Whom even a yankee pedlar could not cheat,
Full of finesse, and paltry cunning tricks,
As rogues who shine in party politics,
Once met in a cockcomb with less brains than cash,
Who therefore undertook to cut a dash
By dint of money, having nought beside
To form the underpinning of his pride.
"May't please your honor, sir," the urchin said,
"Give me two cents to buy some ginger-bread."
"I give you cents!—you little vile clod-hopper,
Two kicks I'll give you, sooner than one copper."
"Give you two cents!—that would indeed be funny."
"You stand in need of *manners* more than *money*."
"Sir," said the lad, "I ask your honor's pardon."
"My case you must acknowledge is a hard one;
For neither cash nor manners I can boast of,
I therefore ask'd for what *you* had the most of."

FOR THE NEW ENGLAND FARMER.

THE SCHOLAR WHO LOST HIS KEY-HOLE.

A scholar, once, who had been drinking till he
Was quite impertinent and somewhat silly,
Came reeling home 'twixt twelve and one at night,
Fumbling his way to bed without a light,
But bellows out as loud as he could roar,
"Some rogue has stol'n the key-hole to my door!"

From the American Daily Advertiser.

Extract of a letter from an American gentleman in Smyrna, dated 27th May last, to his friend in Philadelphia

"Our situation in this country continues to be very distressing, and our future prospects most uncertain. Notwithstanding the strong hopes that now exist, that a war with Russia will not take place, I must confess, I cannot much flatter myself with that hope. The Turks, by their conduct, will force Russia, if not eventually all the Christian powers, to declare war against them. The Island of Scio, containing a population of about one hundred and fifty thousand, has been taken by the Turks. This island was by far the richest of any of the Archipelago. The Turks, on their appearance, held out promises of pardon; they met with scarcely any resistance, still all the men have been killed, and the women and children made slaves, and daily pass through this place, on their way to different parts of Asia. To behold a young lady of respectable family, brought up in all the ease of affluence, a slave to some Turkish Boor, is most distressing. Other scenes, far worse, we are obliged to see and hear of daily. Strict orders are given to prevent any of these slaves from being sold to any Christian; still, however, a few, very few, are saved in this way, at a great expense.

"The Turkish fleet and the Greeks are now in presence of each other; the force of the latter is very inferior to the former, still they do not venture to attack them. The Greeks wait to find them at anchor, with the hopes of burning them; should they succeed, we may expect great disturbances here."

About 60 blacks were convicted at Charleston, for being concerned in the late conspiracy, 34 of whom were executed, and the rest sentenced to be transported.

From the Baltimore Patriot of August 14.

DROUGHT.

The northern and western parts of Maryland, and the adjacent parts of Pennsylvania, have suffered from a drought this season to a degree, unprecedented within the memory of the oldest persons living. In York, (Penn.) no rains of consequence had taken place on the 13th inst. from the preceding 21st of February, the time of the fresh—and for the last two months, there had not been a shower. Not one mill out of ten could grind at all, and the few that could, were not able to supply the demand. Farmers have been obliged to go twenty miles, to get as much ground as would support their families. The York paper seriously states, that a few weeks more of dry weather, would compel the inhabitants to resort to Baltimore for flour! The summer crops have almost altogether failed.—"Some fields will not yield a grain of Corn, and the best of them not more than a few bushels to the acre." Verbal reports and letters confirm these statements, and in fact, give even more gloomy views of the state of the crops and the streams in the adjacent part of our state.

The York Gazette says, "we hear daily of springs that were considered never-failing, disappearing, and the people, like the thirsty throng of Israel, have to go miles in quest of water to sustain themselves."

Although nothing like the distress alluded to, has been experienced in Baltimore and its vicinity, the season has been of late very dry. Yesterday the dried plains received partial refreshment from timely showers, which have caused a perceptible difference in the atmosphere.

From a Philadelphia Paper of August 17.

We were yesterday highly gratified with the sight of a man walking on the water by the help of the *life preserver*. He jumped boldly into the middle of the Delaware, and made his way against the tide with apparently but little exertion. The length of time which it took to put on and adjust the dress, struck most of those present as a serious objection, but we learn that this inconvenience will be remedied in a new dress which the inventor is now preparing; and we have no doubt that the invention may prove useful in cases of shipwreck near land, where, not unfrequently, if only one can escape to shore, means may be obtained of saving the whole crew.

President Adams has recently given in immediate possession to his native town, Quincy, nearly two hundred acres of land, containing in a part of it an inexhaustible quarry of stone for building houses; the whole proceeds to be appropriated to religious and literary purposes from generation to generation. He has also given to the town his whole library consisting of highly valuable books, in various languages. This has already come into possession of the town.

Portsmouth Journal.

An eminent Physician, who was acquainted with the dangerous effects of Lead on the human constitution, recommended those who received their supply of water through *London Pipes*, to have the water which had been standing in the pipes through the night, drawn off every morning, before they draw for the use of their families.

CHOICE OF A WIFE.

As notwithstanding all that wit, or malice, or pride, or prudence, will be able to suggest, men and women must at last pass their lives together; I have never, therefore, thought those writers friends to human happiness, who endeavor to excite in either sex a general contempt or suspicion of the other. To persuade those who are entering the world, and looking all abroad for a suitable associate, that all are equally vicious, or equally ridiculous; that they who trust are certainly betrayed, and they who esteem are always disappointed, is not to awaken judgment, but to inflame temerity. Without hope there can be no caution. Those who are convinced that no reason for preference can be found, will never harass their thoughts with doubt and deliberation; they will resolve, since they are doomed to misery, that no needless anxiety shall disturb their quiet, they will plunge at hazard into the crowd, and snatch the first hand that shall be held towards them. That the world is over-run with vice cannot be denied; but vice, however predominant, has not yet gained unlimited dominion. Therefore, those who undertake to initiate the young and ignorant in the knowledge of life, should be careful to inculcate the possibility of virtue and happiness, and to encourage endeavors by prospects of success.—*Johnson.*

There is a dear and precious period in the life of man, which, brief as sweet, is best appreciated in recollection; when but to exist is to enjoy; when the rapid pulse throbs wildly with the vague delight which fills the careless heart, and when it may be truly said, that nothing is, but what is not.

There is not the greatest man living but may stand in need of the meanest, as much as the meanest does of him.

When the heart is deeply involved, every sense allies itself to its feelings, and the eye beholds no object, and the ear receives no sound, which, in the first impression, awakens not the master pulse of emotion.

Relations take the greatest liberties, and give the least assistance. If a stranger cannot help us with his purse, he will not insult us with his comments; but with relations, it mostly happens, that they are the veriest misers with regard to their property, but perfect prodigals in the article of advice.

PRONUNCIATION.

Sir David Dundas spoke in Parliament with a broad Scotch accent. "I say, Mr. Speaker," said he upon one occasion, "it is not in the poor [power] of this house to do so." "What," said a country member, "does the advocate of Scotland mean by talking of the poor of this house?" "He means, I suppose," said Mr. F., "the forty-five Scotch members."

A person having asked his physician how much daily food was required to nourish and support the body, the physician replied, "One pound of food will support man; should he take more, the man must support the food."

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I.

BOSTON, SATURDAY, SEPTEMBER 7, 1822.

No. 6.

At the suggestion of a friend, but in perfect accordance with our own views, we this day commence the re-publication of the following pamphlet, which we shall continue, from time to time, till completed. Although not designed particularly for this section of the Union, it is, for the most part, as well adapted to New England as to New York; and we think its contents cannot fail to be interesting to that class in the community, who have most leisure to read, and may be expected to derive most profit from reading. Writings like the following have a tendency to make the most useful pursuits the most fashionable, and may perhaps turn the attention of many young men of family and fortune to almost the only honorable vocation, which is not already thronged and crowded to a degree which leaves but little chance of success to new competitors.

Considerations on the necessity of establishing an Agricultural College, and having more of the children of wealthy citizens educated for the profession of farming. Albany: Websters & Skinners, pp. 42.

The purpose of the following observations is to recommend an institution for the education of agriculturists, or, in more familiar language, to teach the business of farming.

The necessity of such an institution is the first thing that will be required to be shewn before advocates for it can be expected, and this I think will appear in a convincing manner from the following considerations.

There are now thousands of wealthy citizens in this state who do not know what to do with their sons. In the first place, without any determinate object in view, they give them a liberal education, or rather, they send them for our years to a college to obtain the reputation of having a graduate's diploma, and so much instruction in the dead languages and the ordinary sciences as they are compelled or disposed to attend to; after that there are only three professions from which ordinarily they are to choose their means of living and rising into consequence—law, physic and divinity; but so great are the numbers of young gentlemen desired for those professions, that their prospects are truly dismal; but what other provision can their fathers make for them? Turn them to some mechanic employment? that is considered too degrading—To manufacturing? it has been tried and proved ruinous—To mercantile business? that too is overstocked—To the army or navy? there is little room there, and many reasons against it—To farming? nothing, it is said, can be made by it.

In most European countries, the manufacturing department affords a vast opening for respectable enterprise, and gives employment to millions. Its business can scarcely be overdone. It is found some of the most important and influential men of the nation to which they belong. In respectability, wealth and usefulness, even in other departments excel them. Hitherto, without offence to the most fastidious pride, may the offspring of families of every rank be directed for employment. To us this department may in some sense be said to be absolutely shut, a circumstance which most un-

terially narrows the field of profitable and honorable pursuit. With us so few are the channels of what is esteemed exclusively reputable business, by the proud classes of society, that a multitude, too great for their capacities, rushes into them at once. Happily for the agricultural department, it has, among all the capricious and absurd modifications and revolutions of notions, remained exempt from dishonorable imputation; but still it is guarded by a terrific phantom, which threatens obscurity and poverty to those who shall attempt to enter it, still repeating, that *by farming nothing is to be made.*

That nothing is to be made by farming, however, is an opinion easy to be refuted, and that will presently be done; in the mean while, some further preliminary observations are to be made.

There are no entailed estates in our country; and there are very few, however enormous, that may not be dissipated by the immediate descendants of those who have acquired them. It may therefore be said, with little qualification, that every person, whatever may be his patrimony, must calculate on being the arbiter of his own fortune. As many young men are now brought up in opulent families, the inevitable consequence will be that they, excepting such as may fortunately escape the effects of their education, must eventually sink out of sight from the respectable part of the community. In the mean time the descendants of the industrious mechanics, following the lessons and examples of their fathers, together with those extraordinary geniuses, that not unfrequently rise from the mansions of obscurity, will by their native powers and unsubduable energies, mount to the highest eminences, command the wealth, and rule the destinies of their country. It is melancholy to look back and see how many families of high repute, have, merely by fostering a despicable, inert, family pride, and disdaining such occupations for their children as were only suited to their talents, and abandoning them to their wayward inclinations, become exterminated from the ranks in which they formerly stood. And it is pitiable, truly pitiable, to see, as any one in every section of the country may see, by looking not far about him, a family raised to opulence and character by the genius, enterprise and industry of its head, exhibiting, from the same cause, sure and dismal presages of its speedily submerging far below the level of its present stand in society.—Who cannot point to some such in which not one of its branches can be selected with the least prospect of a surviving reputation distinguished from that of the common mass of mankind, after the head of it shall have ceased to uphold it? And how is this to be accounted for? By that same pernicious pride and most culpable tenderness, which forbid persons, elevated by their circumstances but a little above the common level, to subject their children to that severe discipline which is indispensably necessary to prepare them for such callings, no matter which, as are indicated by their capacities and the natural bent of their dispositions. Such persons do to their sons the office of the angel of paradise, in guarding, a-

gainst their entrance, the only place where happiness for them is to be found. Nor can it escape observation, that to the neglect of early and systematic religious and moral instruction, can evidently be traced the annihilation of families once holding conspicuous stations in the community.

It may here be proper also to make some remarks on the notion which is generally entertained of the hard-hips, sometimes called cruelties, of discipline. The discipline of young persons is nothing more than compelling them to do what they ought to do, and must do, to escape a comparatively ignominious life, but what they are naturally unwilling to do, and by proper means to impress on them the habit of doing it. This in the operation may not be pleasant to the patient, but the habit once induced will become the source of his greatest enjoyments. As some confirmation of the truth of this remark, I have heard persons, who had in their earlier age passed through a course of the severest discipline, animadvert on it with the highest satisfaction; and with recollections of gratitude to their, once considered cruel, masters, ascribe to it all the consequence they had acquired in life. On the contrary, I have heard bitter upbraidings from those who have in after life woefully experienced the effect of its not having been enforced by those who had the control of them in the days of their infancy and youth.

I believe every reader of this will, from his own experience, be ready to testify to the justice of this remark. For myself I can truly say, that there is no hardship which I have suffered to prepare me for the duties of life, nor any which I have endured in the prosecution of them, which I now regret. If I have any one thing more than others to regret, in my recollections of the past, it is, that stronger injunctions have not been enforced, or that a greater self-control, and a course of more scrupulous and assiduous performance of duties have not been assumed. The pains of additional labor would have been abundantly compensated by the feelings of self-applause, which a retrospection would afford, and the satisfaction yielded by a consciousness of powers better matured for actions more extensively useful.

On this topic I will make one other remark which, as to its importance and truth, I recommend to the serious and deliberate consideration of those wealthy parents, whose anxieties to provide for the happiness of their children, render them incapable of attending to the plainest dictates of reason and the most impressive lessons of experience.

A youth supplied with cash to the amount of his wishes, to be employed for his pleasures in such ways as his undisciplined inclinations may lead him into, and which will most probably be to dissipated company, gambling houses, and the resorts of obscenity and intemperance, will enjoy much less real happiness than an apprentice under the strictest master of a mechanic art. Besides, such a youth must expect ultimately to find the apprentice of the mechanic, and many a farmer's son, infinitely his superior in the estimation

comforts; and if he has any reflection, he will look back with bitter but unavailing regret on the cruel indulgence of his parents. Better for him would it have been if he had been the offspring of poverty, or, as is sometimes the melancholy fact, better that he never had been born. But should he, by a happy constitution, or a fortunate concurrence of circumstances, be kept from the paths of dishonor and vice, still the chance is great that his pursuits will be after frivolous objects, and that his character through life will be marked with the stamp of insignificance. To such a doom do many of our most wealthy and respectable citizens deliberately devote their offspring. Cruel parents! Neglecting to bring up a son to any business, trade or profession, whatever may be the rank or condition of the parent, is a crime of the deepest die—it is next to murder—it is the same thing as cutting off from society one of its members, whose usefulness, if a due discharge of parental duty had not been omitted, might have been eminently great—it is more—it is letting loose on society one, who, as he has not been taught to do any thing useful, must of necessity do mischief, for inaction is unnatural. If his constitutional powers, temper and disposition happen fortunately to be feeble, mild and spiritless, he may be comparatively harmless. But the greater his powers, the more ardent his temper, the more perverse his disposition, and the more inflated his pride, and these commonly go together, the greater is the evil to be apprehended from him—it is a parent's devoting his child to that unhappy existence, which is the inevitable lot of all who are not put into the road of useful employment, and often it happens that it is also consigning him to ignominy, coupled with every calamity of life in its most terrible form—it is a crime of the worst kind against the community—it is one of the most cruel curses that a father can inflict on a son.*

Let the biographies of eminent men be consulted, and it will be seen, that, superadded to the ordinary severities of their instructors or masters, their distinction is to be chiefly ascribed to *self-imposed* severities, deliberately adopted and perseveringly observed, till they have rivited the habits that gave the complexion of their fortunes and determined their destinies. Such men have in their education and subsequent pursuits submitted themselves to privations and toils compared with which the apprenticeship and labors of the most active farmer may be said to be but of trifling amount. Without such self-imposed discipline, Franklin would not have risen above the standing of an ordinary printer. Washington, whose name is encircled with a halo of glory unparalleled among mortals, would have been confounded with the common planters of Virginia, had he not, from early life, subjected himself to a uniform series of labors and sufferings, both of body and mind, of which the most industrious farmer or mechanic cannot form an adequate idea. It is nevertheless true, however, that the innate greatness of such men gives them a sublimity of feeling that makes their labors and sufferings

comparatively light. And so will it be with all who undertake a profession with that exalted enthusiasm which is not to be daunted, nor chilled for a moment, by prospects of the greatest obstacles, but, ever confident of victory, will encounter them with the utmost promptitude and alacrity, however formidable and appalling their character or appearances may be.

The chief difference between the noble and ignoble of the human race is this: The one, after having obtained a distinct view of his duties, and the necessary means for attaining a noble end, prescribes to himself a conduct for accomplishing his purposes from which he will never deviate, whatever may be the temptations or discouragements to induce him to relinquish it or to relax in his efforts. The other will, on the appearance of every little difficulty, shrink into himself like a snail, or sink into a helpless state of despondency.

Read the *choice of Hercules* when addressed by *Fame and Pleasure*, personified as deities. Had he been intimidated by the labors which the first required of him, or accepted, like many an unfortunate youth of our times, of the promised dalliances of the other, instead of obtaining an immortal fame, he would have sunk, a miserable, debauched, effeminate wretch, into the gulf of oblivion.

Nothing is more idle or preposterous than the notion that success or celebrity, in any sphere, can be obtained without great exertion and intense application. Reason, at the first glance, pronounces it foolish; and every day's observation shows it to be false; and yet it seems, some parents think that their sons will become *something* without any labor to qualify them for it, and as a consequence, their sons dream of distinctions without an effort to attain them. They expect to glide smoothly down stream on the credit of a family name, or a family's riches, or possibly on the reputation of a superior genius, without the necessity of combatting contrary winds and currents, into a port where accumulations of wealth and honor await them. Miserable dreams! fatal delusions! No young men must have it impressed on them, as an undeniable self-evident proposition, that they must work, and work hard both in qualifying themselves for the business of their profession, whatever that may be, and in conducting it afterwards, if they have any ambition to be seen in the ranks of honorable men; and that all their powers must be strenuously, systematically and perseveringly exerted, if they aim at any thing like superiority.

(TO BE CONTINUED.)

MASSACHUSETTS AGRICULTURAL REPOSITORY AND JOURNAL, FOR JUNE.*

(Continued from p. 22.)

The next article which merits particular attention, is by J. Lowell, Esq. on the culture of Sea Kale, (*Crambe Maritima*), and of the Salsify, or Oyster Plant, (*Tragopogon*.)

Mr. Lowell says these plants were introduced some years since, but their use has not become

common in this country, although they are both favorites at European tables.

"The Sea Kale is a plant of recent introduction in Europe. Perhaps its culture cannot be traced back beyond forty years. It is a native of the sea coast of the Southern parts of England, where it is found growing in sea land.

"It is very hardy—grows in any tolerable soil—is perennial, and costs not half the labor bestowed on asparagus. It may be raised from the seed or from the root, and fifty plants, occupying a very small space, will supply a single family. In its taste it resembles the Cauliflower. The only labor it requires is to cover it with sand, or earth, or with pots, or boxes in March so as to exclude the light, and to blanch it, or make it white. If not blanched it is neither so beautiful to the eye, or so tender, or so delicate to the taste as if blanched. It should be thoroughly boiled, and is better if boiled in milk and water. It should be served up like Cauli flowers, with melted butter. It comes in at a season in which our vegetables in this country are very deficient.

"If in England and France, where it has to compare at the same table with green peas and spinach, it is admired as a luxury, can it be possible that it will not eventually succeed with us? We shall be happy to furnish seeds of it to any persons who may be disposed to introduce it."

"If in older countries, with milder and shorter winters, in which they give you green vegetables nine months in the year, they value such a plant as the Sea Kale, it must be of great value to us, whose soil is bound in frost from the 10th of November to the first of April, at sterile till the first of May."

"It requires no manure as the Asparagus does. It is indeed injured by it, and if our farmers in the interior had a patch of it in the gardens, they would have an earlier succulent vegetable to eat with their salted provision than any other they could raise."

Hill's British Herbal remarks that, "The people about the sea coasts boil the *Crambe Maritima*, in the way of savoy and cabbage and the like; and it is very well tasted and perfectly wholesome. This had led some to take it into their gardens, and it is preferred to most other kinds at table."

"The Salsify, or Oyster Plant," Mr. Lowell continues, "is another vegetable of easy production, and universally eaten, when introduced to the table. I know no one vegetable which is more esteemed.

"It resembles a small parsnip in its appearance. It is raised annually from seeds, and easily, requiring no more care than the carrot. It bears a tolerable crop. In Europe it is eaten both boiled and fried. In this country it is prepared both ways. It forms an admirable garnish for boiled

publish useful than original matter; and surely circulation of any article which promises advantage to the public ought not to be limited to the publication in which it makes its first appearance. In England it is published in any one of the many scientific periodical works with which the country abounds, it is copied into all the rest. Each paper has generally a share of matter, written for that particular paper, the greater part of its contents is selected from contemporaneous publications.

* The author has been informed, that in a town in this state, not as populous as Albany now is, and not less healthful, out of forty young men of the most respectable families who had reached the age of manhood, and who had not been educated for any profession, not one survived his fortieth year.

* Some persons may, perhaps, think it needless for us to quote largely from a publication which is in the hands of many of our readers. But, we beg leave to observe that the greater part of our subscribers do not take and have no chance to peruse the Massachusetts Agricultural Repository. We are more solicitous to

fowls or turkeys. In its taste, it so strongly resembles the oyster, that when sliced, and fried in batter, it can scarcely be distinguished from it. If our gardeners would introduce it into the market, and our citizens once try it, there would be no danger of its ever failing hereafter to be raised. It is in eating from November to May, precisely the period in which our vegetable market is most deficient in variety."*

Mr. Lowell, in this article, states his confidence in the success of attempts which are making to naturalize the Sweet Potatoe in New England, and says,

"We are confident they will be regularly for sale in Boston market, from this time forward. We have had experience this spring of their hardihood. They encountered a severe frost on the sixth of May, after having been transplanted from a hot bed, where they were made paternally tender. They were cut down by the frost, but have started again more freely than common potatoes. They are now one month earlier, than any we ever raised, and we feel no doubt that they will produce an abundant crop, and those which will not sell, will furnish the best possible food, for pigs, cows, and poultry. This is no speculative theory, but the result of four years constant observations and experiment. We have no idea of its being an object of general culture, but it will, and must form a part of the cultivation for the market, and of gentlemen, who feel a taste for horticulture."

The next articles are long, and relate entirely to Horticulture. The writer in an introduction to "Extracts from the Horticultural Transactions," complains that

"We are utterly destitute, in New England, of nurseries for fruit trees on an extensive scale. We have no cultivators on whom we can call for a supply of the most common plants of the smaller fruits, such as strawberries, gooseberries, raspberries of the superior kinds—we have no place to which we can go for plants to ornament our grounds—we have not a single seedsman, who can always furnish us with fresh seeds of annual flowers on which we can place a reliance. These are trifling evils compared to the want of bread, but when we are filled with abundance, we look round for something to gratify our tastes."

"Let those, who please, laugh at the absurd-

*Rees' Cyclopaedia observes, in substance, that the talks of the Tragopogon, or Salsafie "may be cut in the spring, when they are four or five inches high, and dressed like asparagus, in which way they eat very tender and well;" and gives the following

"Method of Culture.—The seed should be sown in the spring, in an open situation to remain, either broadcast and raked in, or in shallow drills eight or nine inches asunder, scattering the seeds thinly, and covering them half an inch deep; and when the plants are come up two or three inches in height, they should be thinned and weeded by hand or the hoe, leaving them eight or ten inches asunder, repeating as required, during the summer, which is all the culture they require, and they will have large roots by the autumn, as early as September or October, when they may be begun making up for use; and in November, when the leaves begin to decay, a quantity should be preserved in sand or use, when those in the ground cannot be got up.

"In the spring, when those remaining in the ground begin to shoot, the shoots, when a few inches high, may be cut for use, which, when quite young and tender, on being boiled are excellent eating. The roots are brought to market in bunches during the autumnal and winter seasons."

ity of talking seriously of the importance of raising ornamental trees, shrubs, and herbaceous flowering plants; let them ridicule the zeal, which would furnish us with all the varieties of fruits, which grow from Palestine to Archangel, which would supply our tables with lettuce in February, and green pease in March, yet there are few of these laughing gentlemen who would not gladly see and taste these rarities, and they must be had, and will be had in spite of ridicule. They are in truth as rational sources of pleasure, and as just objects of pride and display as a fine carriage, or superb dresses. They in truth, give more general pleasure; for while the coach and the muslin robe are chiefly gratifying to the owner, those who cannot afford either the one or the other, *can feel*, and often do feel, more exquisitely, the pleasures derived from the display of the beauties of flowers, or the taste of the delicious fruits of nature. The cultivator then of fruits and flowers is much less selfish. Their sweets are not produced for him alone. He can derive little pleasure from them, but by their distribution."

"To shew the utter incompetency of our own nurseries (if the few we have can be dignified with the name.) I will simply state the fact, that one hundred roots of strawberries, all of which were nearly dead, sold at the late sale at auction for a greater price than fine plants of approved sorts, would be sold for in England, and that raspberry plants sold at such a price, as would have given me six hundred dollars, had I chosen to break up my raspberry plantation and send the plants to auction; and I could have guaranteed better plants and better sorts than any which could be expected in a promiscuous importation and as good as can be found in Europe. This shews the demand and the inadequacy of supply."

(TO BE CONTINUED.)

WORCESTER COUNTY

CATTLE SHOW, EXHIBITION OF MANUFACTURES, AND PLOUGHING MATCH,

At Worcester, on Wednesday, September 25, 1822.

The Committee of Arrangements, appointed by the Trustees of the Worcester County Agricultural Society, give notice, that in the discharge of their duty, every accommodation will be afforded to the citizens of the county and the public, which this interesting occasion may demand. From communications which have been made to them, they have the pleasure of anticipating a more excellent Show of Cattle and a finer Exhibition of Manufactured Articles than in any preceding year, and they doubt not of the best endeavors of the industrious, spirited and prosperous inhabitants of this extensive, populous and rich county, to render the day most highly creditable to their exertions, and eminently gratifying to the numerous and distinguished strangers, who may honor it by their attendance.

The Ploughing Match will lead in the exercises of the day. The Teams must be on the Field, prepared to start at 9 o'clock, A. M. precisely. By the rules of the Trustees, "those persons who design to become competitors, must give notice in writing to the Recording Secretary, on or before the 15th of September next, that suitable ground may be obtained, the proper number of lots measured and marked out,

and the requisite arrangements made for the occasion.

A Procession will be formed, immediately after the Ploughing Match, of the Officers and Members of the Society and of invited strangers, and proceed to the South Meeting-house, where Prayers will be offered by the Chaplain of the day, and an Address will be delivered by a Member of the Board of Trustees.

The Pens for the Cattle will be erected on the Common, near the Meeting-house.

The Procession will be conducted from the Meeting-house, into the area between the ranges of Pens, for the examination of the Animals.

The trial of Working Oxen will follow the examination of the Stock.

The Examination of Manufactures will be attended to *in private*, by the Committee appointed to that duty on Tuesday the 24th of September, and the articles must be entered with the Recording Secretary, and delivered to the person appointed to receive them before 11 o'clock of the forenoon of that day. These articles, together with whatever is curious and wonderful in fabric, or in the product of the Earth, will be publicly exhibited in the Rooms of the Society from 9 o'clock, A. M. until 5 o'clock, P. M. of the 25th. The citizens of the county are respectfully and earnestly solicited to contribute to the interest in the Exhibition, by sending to the Rooms any article in their possession, which may be worthy of observation, although it may not be of the description advertised for Premium. The most faithful attention will be paid to preserve every thing from injury, and to restore the property to the respective owners. The Rooms for the Exhibition, are furnished to the use of the Society by the liberality of Major Flagg, and are the same which were used the last year.

The Funds of the Society will not admit of further gratuities for the Exhibition of Teams of Cattle from the neighboring towns, but the Committee trust in the public spirit of their fellow citizens that the high gratification afforded by the fine display made by the good yeomanry of Sutton and Shrewsbury, the two last years, will be renewed at the approaching Cattle Show, by similar Exhibitions from those and other conveniently situated towns of the county.

The respective Committees of Premiums will make their Reports, and the Premiums will be awarded in the Meeting-house, at five o'clock, P. M.

Marshals are appointed and will be under oath, to enforce the Rules and Regulations of the Trustees, and to preserve good order on the occasion.

God speed the plough, and give success to the Spindle, the Shuttle, and the Loom!

LEVI LINCOLN, THEOPHILUS WHEELER, OLIVER FISKE, THOMAS CHAMBERLAIN, NATHAN HOWE,	} Committee of Arrangements.
--	------------------------------------

Worcester, Aug. 28, 1822.

Mr. Isaiah J. Hendrix, of Bennington, (Vt.) has lately invented, and obtained a patent for an instrument called the Delineator, to be used in the cutting of garments. Being fitted for the fashion required, it shows with precision all the points necessary to be found in cutting for any size or proportion.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.

LIQUID MANURE.

Mr. Robert Smith, President of the Maryland Agricultural Society, gives the following account (which is taken from the *American Farmer*) of the arrangements he has made for the preservation and application of the liquid manure, yielded by his stables and barn yard at Orange, two miles from the city of Baltimore.

"The yard is situated to the south of the barn; on its east and west sides are built cow-stables, which extend almost the whole length of the yard. In these stables, well ventilated, are several ranges of cattle standing in separate stalls, and each secured by a chain and halter. At the tails of each range of cows, there is a drain, made of strong planks fourteen inches wide, and twelve inches deep, and so fixed as to receive all their dung and urine. These several drains have a sufficient declivity to carry all fluid matter to their southern terminations, where they intersect similar drains, which convey all their liquid manure into a cistern fifty feet long, six feet wide and six feet deep. This cistern is so placed and constructed as to receive not only the urine of the stables, but also all the liquid matter of the farm yard. In it there is a pump by means of which its contents are pumped into a large hogshead fixed on a pair of wheels drawn by oxen. To the end of this hogshead is attached a box, pierced with holes, into which this liquid matter flows through a spigot and faucet, and is then sprinkled over the ground as the oxen move forward. Before these drains had been made, the stables, notwithstanding the greatest exertions of two pains-taking men, were so wet and dirty that the cattle could not be kept free from filth. But since they have been made, the stables have been dry and clean, so as to be comfortable to the cows, and agreeable to the milkers. But this is not all. One man has now so little difficulty in cleaning the stables that he has time enough for the currying of all the cows in the most perfect manner. At the time of laying these drains, I was somewhat apprehensive that they would prove too deep; but experience has shewn, that they have the recommendation of convenience as well as of cleanliness. Were they but five or six inches deep the cattle would often stand with their hind feet in them, and in such case the advantages of the drains would be but partially obtained.

"In the middle of the farm-yard is a large trough supplied with water for the stock from a hydrant. This water is conveyed in pipes under ground from the milk house. A line of these pipes I am about laying so as to have a hydrant at the upper end of every drain to furnish water for the washing of the stables. All the water employed in this operation, carrying with it the dirt of the stables, will flow down the drain into the cistern to the no inconsiderable increase of its invaluable contents.

"The urine in the cistern contains not only its own constituent fertilizing properties, but it is also highly impregnated with certain portions of the dung with which it had been mixed, and among which it had flowed. The beneficial effects of this species of manure are practically known to all farmers. And Sir Humphrey Davy and other chemists have assured us that urine contains in a state of solution the essential ele-

ments of vegetables. The highly celebrated author of the *Code of Agriculture*, has, moreover, stated that Mr. Harvey, of Glasgow, by using cow urine has cut grass six times in a season, and that the average of each cutting was fifteen inches in length."

Should the farmer think that drains, of the above description, would be too expensive, he may obtain some practical hints from the following observations by Sir Humphrey Davy.

"When dung is to be preserved for any time, the situation in which it is kept is of importance. It should, if possible, be defended from the sun. To preserve it under sheds would be of great use; or to make the site of a dunghill on the north side of a wall or building. The floor, or place, on which the dung is heaped, should, if possible, be paved with flat stones; and there should be a little inclination from each side towards the centre, in which there should be drains connected with a small well, or cistern, furnished with a pump, by which any fluid matter may be collected for the use of the land. It too often happens that a dense mucilaginous and extractive fluid is suffered to drain away from the dunghill so as to be entirely lost to the farm."

The Complete Grazier says that "Urine or the liquor of farm-yards, is a fluid capable of being employed with great benefit both on *meadows* (mowing lands) and arable land, which renders them uncommonly fertile. It should be used as fresh as possible, as the soluble animal matter it contains is destroyed by putrefaction; and if not mixed with solid matter should be diluted with water, as, when pure, it contains too much animal matter to form a proper fluid nourishment for absorption by the roots of plants.

"In order to make the most of this valuable manure it should be carried to the mowing land or pasture intended to be watered in dry weather, as the farm yard liquor in the reservoirs is at that time strongly impregnated with salts, which may be known by its deep brown tinge. Thus the reservoirs, or ponds, appropriated for its reception, may be constantly kept in a state of readiness for that purpose; while the land may be watered or sprinkled as often as the operation may be necessary.

"An interesting account of an economical mode of collecting and applying the urine of cattle as a manure to land, has been communicated in No. XLIX, of the *Farmer's Magazine*, by an intelligent farmer, Mr. Charles Alexander, in the vicinity of Peebles. His farm buildings are so disposed, that the urine of all the stalls is conveyed by trunks into a dung pit; and the dung is laid in a place appropriated for that use, instead of being thrown into the middle of the yard, according to the usual practice. The dung pit is twelve yards square, and four feet deep, and is filled with mould previously carried into it, for the purpose of being impregnated with the urine and moisture from the dung. This pit produces about 238 cart-loads, forty of which are sufficient for an acre. The dung itself is laid on the land in the common way; but the compost, made by the urine, &c. with the mould, is spread on the surface after ploughing, and is merely harrowed in."

NEW APPLICATION OF PLASTER OF PARIS.

A correspondent to the *American Farmer* says that he has ascertained by experiment that

plastering clover *largely* at the time of turning it down, and preparing for a wheat crop, is by far the most advantageous to the crop, and much preferable to turning in the clover in the usual way and plastering on the surface. He states that "the action of the plaster, thus excluded from atmospheric air, upon the clover, covered over, is instantaneous, and the putridity is so certain as to cause considerable gas, which in its passage through the clod, impregnates it with all its manuring qualities, and the root of the plant shoots down and feeds on a bed of manure."

ON THE FORMATION OF MORTAR.

Extract from an Essay of James Anderson, L.L.D. F.R.S.

"The best modern mortar I ever saw, was made of lime that I myself had analyzed, and found it contained eleven parts of sand to one of lime.—To this there was added between twice and thrice its whole bulk of sand by *measure*, which may be allowed to have been at least three times its quantity by *weight*.

"Now supposing that every particle of that lime had been so perfectly calcined as to be in a caustic state, there could not be less than forty seven parts of sand to one of lime. The reader may allow what he pleases for the uncaustic part of the lime, and make his calculation accordingly. But it is hardly possible to suppose, that above one hundredth part of this mass, independent of the water, consisted of pure caustic calcareous earth.

"But whatever was the exact proportion of caustic lime, the mortar was made of these materials in proportions expressed, and was employed for pinning the outside joints of the stone wall of a house situated in a tempestuous climate, and exposed to every blast. It is now about fourteen years since it was finished, and I do not believe there has fallen to the ground in all that time, one pound weight of the mortar.*

"Had this mortar been employed in building a thick wall, where it would have been suffered to dry slow enough, there seems to be little reason to doubt but it would in time have become as firm as the stones of the wall itself.

"From these considerations we may clearly see, that it is impossible to prescribe any determinate proportion of sand to lime, as this must vary according to the nature of the lime and other incidental circumstances, which would be tiresome to enumerate, and which would form an infinity of exceptions to an general rule.

"But it would seem, we might safely infer that the moderns in general, rather err in giving too little sand, than in giving too much.

"It deserves, however, to be remarked, that the sand, when naturally in the lime-stone, more intimately blended with the lime than can possibly be ever effected by any mechanical operation—so that it would be in vain to hope to make good mortar artificially from pure lime, with such a small proportion of caustic calcareous matter, as may sometimes be effected when the lime naturally contains a very large proportion of sand. But there seems to be no doubt that if a much larger proportion

*In a note to a second edition of this work is the following addition:—"After seven years longer trial the mortar still proves good and firm, and exhibits no appearance of ever falling."

sand were employed, and if that were more carefully blended, and expeditiously worked, than is common, the mortar would be much more perfect than usual in modern times.

"This I have tried experimentally, with the desired success."

From the N. England Journal of Medicine and Surgery.

Messrs. Editors,

If you think a publication of the following facts which I have obtained by reading some late writers upon the subjects to which they relate, will be of any public utility, you are at liberty to insert them in your valuable Journal.

J. B. BROWN.

A knowledge of the diseases of animals in general, cannot be inferred from a knowledge of the diseases of any one particular species of animals.

Thus he who is acquainted with the diseases of the horse, would not from that circumstance be able to prescribe correctly for the diseases of quadrupeds generally. The anatomy and physiology of animals differ. For example, the dog has no insensible perspiration. The mouth of the horse performs but one office, that of conveying food to the stomach. It conveys nothing to the lungs or from them. It has nothing to do with the modulation of his voice, as in most quadrupeds and in man. The passages to the lungs and to the stomach in the horse, are distinct.

The horse unlike most other quadrupeds has no gall-bladder, notwithstanding a work which has been through twelve editions, and one at least in this country, (Taplin's Farriery) gives a particular description of the diseases of the gall-bladder, and the symptoms of those diseases.

It has been stated above, that the anatomy and physiology of animals differ, so also do their diseases.

The horse is not subject to fever, i. e. he has no simple, idiopathic fever, no cold, hot and sweating stage, as man has. The feverish action, which the heart and arteries of the horse sometimes assume is sympathetic, and is always preceded by some local affection. It is a disease of irritation.

The eyes of the horse are subject to a species of cataract, that affects no other animal. It arises from a constitutional disease, brought on by bad stabling. It is never produced by local injury. This species of cataract commences with an inflammation of the conjunctiva, without any apparent cause. Local applications have no effect in removing it. The only rational method of treating it is to remove, if possible, the constitutional disease and improve the health and condition of the animal.

Oxen and cows have the disease called bots in their skin, but in the horse this disease (if it may be so called) is confined to the stomach.

Farcy and glanders, I believe, are diseases peculiar to the horse. I know of no other animal subject to them. They are contagious diseases, but may be produced without contagion, by bad stabling. The poisonous matter of farcy will produce glanders, and *vice versa*. Farcy is now ascertained to be a disease of the superficial absorbents; whereas in all the old books on the veterinary art, it is represented as a disease of the veins.

A horse glandered has the whole mass of blood contaminated. This may be considered by medical gentlemen as an important fact, as it goes to prove the doctrine of humoral pathology. That the whole mass of blood is diseased in a horse affected with glanders has been proved by the following experiment made by Mr. Coleman, Professor at the Veterinary Institution, England.

He took a young healthy ass, an animal, as he states, peculiarly susceptible of the disease, and introduced a pipe having a stop cock into the jugular vein, united by means of an ureter to another pipe, which he introduced into the carotid artery of a glandered horse. He then bled the ass to death, by opening his carotid artery, and turning the stop cock, admitted the blood of the horse into his vessels, and resuscitated him. The result was that the ass became violently glandered. He inoculated other asses from the matter produced in him, and was able to carry on the same disease.

Corns in the feet of horses are very unlike corns on the feet of the human subject. There is nothing which grows in the feet of horses that constitutes corns. There is no increase of substance. Corns in the feet of horses are mere bruises. Every body has seen or experienced the effects of bruises upon the human nail. Corns in the feet of horses are injuries of a similar nature. The red appearance which they have is caused by an extravasation of blood which spreads itself among the fibres of the horny hoof. Corns are generally occasioned by the shoe. They may, however, arise from other injuries. They are easily cured by suitable remedies and a proper mode of shoeing, unless the inflammation occasioned by the injury has been of long standing and assumed a chronic character. In this case the cure is more tedious.

Horse ail.—I will take this opportunity to make a few remarks on the nature of this complaint.

Strictly speaking, all diseases of horses are *horse ails*; but custom has given this epithet to a species of disease very common among our horses. The disease referred to, is called *strangles* in most of the old books on Farriery. It consists in an inflammation of the membrane lining the nose and the arytenoid cartilages. This disease is accompanied by a cough and a discharge from the nostrils. The cough is sympathetic, and is produced by the extreme sensibility of the membrane thus inflamed. The lightest dust, or even a drop of water lodged upon this membrane, in this irritable state, produces coughing. The inflammation sometimes extends to the lungs, and then this disease is accompanied with a disease of the chest, and requires speedy and energetic treatment, as inflammation of the lungs in the horse is apt to terminate speedily in gangrene. Copious bleeding, from six to ten quarts at first and smaller bleedings afterwards, as the state of the case may require, and small doses of aloes from one to two drachms, given daily, have been found the most successful remedies in inflammation of the lungs. Drastic purgatives should be avoided, as they increase the irritation, and put the life of the horse in extreme hazard.

It has been stated above, that the diseases of animals differ as much as their anatomy and physiology. The specific effect of medicine upon different animals is no less various than their structure and diseases.

Glauber's salts in doses of one pound operate on the horse as a cathartic, but on the horse they operate principally as a diuretic. Castor oil does not operate on the horse as a purgative, any more than train oil or any other oil.

Opium does not produce its specific effect upon the horse. It operates merely as an astringent. It has no anodyne effect, as it has upon man. It will not mitigate pain. It is unfortunate that most writers on the veterinary art have copied from each other, and have recommended medicines for the horse which are known to be useful to men. Thus calomel, rhubarb and colocynth, have been recommended as purgatives for horses, whereas they are now known to have no such effect on that animal.

Bark produces no sensible effect upon the horse.

There are no medicines that operate on the horse as ipecacuanha and tartar emetic do upon the human subject.

Tartar emetic in doses of four ounces will sometimes occasion a little nausea and purging, but in smaller doses it has no sensible effect. No preparation of mercury will produce salivation in the horse. His gums may be made sore by mercury, but pyalism cannot be produced by it.

Sugar of lead which is known to be a most deadly poison to man, the horse can take without injury. Tobacco has no deleterious effect upon the horse.

Hellebore in doses of half a drachm produces a tendency to nausea in the horse. Hemlock is good food for goats, but a deadly poison to man; and wheat, the natural food for man, is poison to the horse. Spirit of turpentine, which an infant may handle without injury, operates as caustic when applied to the skin of a horse, although it may be applied to sores and fungous flesh on that animal without producing pain.

"All great improvements have originated from men who combined science with practice, and there is not at present a more popular pursuit in England, nor a more interesting topic of conversation in well informed circles, than the philosophical and leading doctrines of agriculture. This art is now clearly understood to be the chief support of national greatness and independence; and the various questions in political economy to which it gives rise and affords a solution, all hold a share in the general interest."

Young's Letters of Agricola.

Speaking of Agriculture, the same writer observes, "I hold it as unquestionable, that there is no other art in the whole compass of human ingenuity and skill, which admits of such interesting experiments, of such a clear insight into the laws of matter, of such philosophic contemplation, of such healthy and invigorating exercise, and of such intimate union with all the sciences that ennoble man and exalt him to his just pre-eminence."

THE PLEASURE OF PLEASING.

To a man who possesses a good heart there can be nothing more pleasing than the consciousness of giving pleasure to others. The luxury of doing good is a most exquisite as well as a most innocent luxury to him whose feelings and affections are such as make a man capable of enjoying as well as bestowing happiness.

NEW ENGLAND FARMER.

BOSTON.—SATURDAY, SEPT. 7, 1822.

THOUGHTS ON AGRICULTURE, AND CERTAIN MEANS FOR ITS IMPROVEMENT.

The celebrated Sully declared agriculture to be the breast from which the State must draw its nourishment. Commerce and manufactures he considered as the sinews of the State, and deserving all possible encouragement. But, perhaps the most effectual way to encourage commerce and manufactures is to foster agriculture, which is the parent of all improvement, and the source of all national and individual prosperity. The manufacturer must eat his bread at a moderate price, or his work shop will cease to support him, and he will either drag on a wretched existence in penury and discontent, or seek, by emigration, some amelioration of his circumstances. The merchant, likewise, cannot expect to flourish in a country whose soil is unproductive, and whose inhabitants of course are too poor to afford remittances to sanction his importations.

Merchants and manufacturers, therefore, who are alive to their own interest, will encourage agriculture by all the means in their power, and will be sensible that it is the first and greatest link in that chain of national prosperity, which embraces all ranks in a happy and well regulated community. Agricultural Societies, and Publications on Husbandry, are among the most approved means of giving speed to the plough, and success to the labors of the husbandman, and ought, therefore, to be patronized (as they frequently are) by those pursuits are entirely remote, and apparently foreign from rural occupations.

Every man who cultivates the ground should be ambitious to contribute something from the stock of his knowledge, whether acquired by reading, observation or experience, to the general fund of agricultural information. By this means he may become a benefactor of his species, and be placed higher in the estimation of good men, than the greatest conqueror, who ever waded through seas of blood to the summit of that "bad eminence," which can only be ascended by devils and heroes. If he is convinced that he has made any improvements, which promise to be useful to his fellow creatures, he will not perform the part of a patriot nor philanthropist if he does not put mankind in possession of such improvements. If he can gain any equivalent for his discoveries by virtue of patents, premiums, or otherwise, let him obtain it. If not, he will do well to lay them before the public, and take his reward in the consciousness of having been of service to his fellow creatures. The man, who refuses a benefit which he might bestow without injury to himself, is but little better than one who does an injury without receiving any benefit from the injurious act. The latter destroys human happiness, and the former withholds the means by which happiness might have existed.

It is no apology for these misers, whose thoughts are worth money, and therefore hoarded in their own bosoms, to say that they cannot write in an elegant style, and do not know how to put their ideas upon paper in such a manner as to escape the ridicule of men of learning. If they cannot write elegantly, they may perhaps write naturally, so as to be understood, and nothing more is wanted. If a farmer has discovered some improvement relating to his occupation, which, if generally known, would prove of general utility, and thinks he cannot well describe it in writing, let him tell his story concerning the matter, either to the editor of this paper, or to some other person, who will write off his information in a plain style, and send it to the New England Farmer, or some other periodical work, for publication.

There should be no secrets in agriculture, and whatever concerns the public good, the public should be put in possession of. The benefits which would result from the more general diffusion of agricultural intelligence would be immense, and almost incalculable. We will state a few evils which infest the husbandman, and may be styled the plagues of agriculture, and set down concisely their real or supposed remedies, and leave it for the reader to judge of the advantages which would result from the universal extension of the knowledge of those remedies, which are effective, or of others more efficient, where they are unavailable.

In some seasons the vegetables in our gardens are almost annihilated by worms of several species. Fall ploughing, or spading the ground just before frost sets in, and strewing the ground with fine salt in the spring some time before the seeds are sown, are said to be sovereign remedies against these petty but powerful depredators.

There is a kind of worm (which the learned call *curculio*) found in apples, pears, and some other sorts of fruit, which either injures or destroys little if any less than one half of the fruit produced in New England. It is said (but the report wants confirmation) that spent tan from the yard of the tanner, spread about the roots of fruit trees, will secure them against these little thieves, who steal every year about one third of the products of our orchards, and injure a considerable part of the remainder. Spent tan, likewise, some suppose, will prove a specific against canker worms and caterpillars. We solicit further information on this subject.

There is another kind of worm, which bores its way into peach trees, locust trees, &c. at or near their roots, which some say should be cut out with a knife, or chisel, and others affirm that soap suds, heated after a family wash, and poured about the roots about the middle of August, will destroy the eggs of the young worm. Unleached ashes and spent tan are likewise recommended.

There is a worm, or maggot, which affects the head of sheep, supposed to be a species of bot, and which it is affirmed may be expelled by injecting vinegar by a syringe into the nostrils of the affected animal. A worm of the same, or different species, is also found on the outside of the head of sheep, at the roots of the wool about the throat, ears, &c. This, we are told, may be destroyed by the application of spirits of turpentine.

There is a worm, called, we believe, the *wire worm*, which destroys seed corn before it vegetates. The attacks of this insect, we are informed, may be guarded against by soaking the seed corn in a solution of common salt, or salt-petre. But if the solution is made too strong, and the seed suffered to remain in it too long, it will destroy the principle of vegetation, and the corn will never come up, unless you dig it up, as we have found to our cost.

Some people affirm that horses affected with bots, and apparently in the last agonies, may be cured almost instantaneously by the external application of spirits of turpentine to the breast. Others advise to turn a dose of spirits of turpentine down the throat of the animal.

Some assert that cattle or sheep, which are hoven or swollen, in consequence of having eaten too much green and succulent food, may be cured by a dose of lye, made with potash, pearlash, or house ashes. Others say that the animal must be stabbed, scientifically, in order to let the gas escape, which is the cause of the disorder.

Some say that elder juice expressed from the leaves

or berries, or even a decoction or tea made of the common elder, but more especially the dwarf elder, will not only destroy maggots in meat, cheese, &c. but sprinkled over cucumber vines, squash vines, &c. will preserve them against the bugs and flies which so often prove destructive to those vegetables. We have very little doubt of the efficacy of elder for the purposes above stated, but should be glad to learn something further on the subject.

We do not pretend to assert that all, or any of the above named remedies are never failing specifics.—Some of them, however, we know to be useful, having witnessed their good effects; and some others we have collected from persons whose veracity and discernment we have no reason to call in question. Now if even a part of those remedies are efficient, their general knowledge and consequent application would save the inhabitants of New England, in one year, more money than they pay in taxes, of every name and nature, in ten years. It costs a farmer, who owns one hundred acres of land under cultivation, more to maintain the worms in his garden and cornfield, the bugs in his peas, the lice upon his cabbages, the caterpillars and canker worms in his orchard, the flies of his turnip yard and dairy, including the Hessian flies of his wheat field, the bots in his horses bellies and sheep's heads, &c. &c. than it would to bring up a family of children, and send one or more sons to an agricultural college, (if we had such an institution) into the bargain.

These diminutive enemies, however, are easily subdued if we knew how to attack them; and we have no doubt but there are individuals who are in possession of information which would enable every farmer to rid himself of the destroyers; and we ardently wish people possessing such information would forward it to us, or some other printers, to be published for the benefit of mankind.

Worcester Cattle Show.—We are sorry that we are not able to publish, at large, in this week's paper, a list of the Premiums, &c. offered by the Worcester County Agricultural Society. The copy was received too late for insertion in the present No. but shall appear in our next.

COMMUNICATION.

We present the following desultory, but we hope well considered remarks, as a *Communication*, because we propose to speak of "THE NEW ENGLAND FARMER," and its titles to attention, and encouragement, and we would not have it appear to be an editorial article. We have never doubted, that a newspaper principally devoted to agricultural subjects would be of great use, but we have entertained fears that farmers and cultivators would not with sufficient zeal and spirit give it their support. Too many of them believe, that they know enough already—that nobody can teach them any thing which is new—that agricultural labor is so simple, that nothing is necessary to the full accomplishment of a farmer, but to mow well, to hoe his land with expedition, to hold the plough, and drive his oxen with skill, and to commit to the soil, to *any* soil, without considering its adaptation to particular plants, the seed, without any reference to the unquestionable and well settled fact, that after one plant has exhausted the soil of the nutriment fitted for it, another will flourish as well as if the former had not been raised upon it—in short, without any ideas of the use of a succession of crops.

The present state of general information, and particularly the greatly advanced state of agri-

cultural knowledge, forbid the continuance of these indolent and degrading opinions. It is perceived that agriculture as well as its coadjutor, manufactures, is susceptible of great and indefinite improvement, and this improvement cannot be extensively and with due rapidity circulated, and promoted, but by journals published more frequently, than the formal and stated journals of the several agricultural societies. There is another reason, besides the more frequent opportunities afforded by newspapers, and their much more extended circulation, which should give them the preference and make them more extensively useful. The periodical journals have more stateliness and formality—they are composed of essays written in a style more elevated and more learned, than communications in a weekly newspaper commonly are. Many intelligent farmers are therefore deterred from communicating their experiments or suggesting their doubts or their inquiries. No man feels the smallest fear of addressing the Editor of a newspaper, secure of secrecy, and equally secure of admission if he suggests any thing ingenious, novel or interesting.

It would seem to be a paradox, or extremely strange, if while our commercial community consisting at the utmost of 500,000 persons can sustain several hundred newspapers, the agricultural interest composed of the residue of the community and amounting to nine millions can support but two or three exclusively devoted to agriculture. It would argue less intelligence, less zeal for their best interests, less desire of improvement among farmers, all which we believe, and hope not to be the case. The truth we believe to be, that they have never been awakened—that they are more quiet, less adventurous, less active, but full as intelligent and full as desirous of improvement when the path is laid open to them.

We have to be sure had newspapers printed in the interior, and agricultural towns, but they have too often been mere copyists of the newspapers of the metropolis. They have, too often, been meagre and dull, with little original matter, and still less of articles devoted to agriculture. Two journals form an exception to this rule—The Plough Boy, printed at Albany, and the American Farmer, printed at Baltimore.—The well merited success of these works entitle the Editors to great praise, and they will have the honor of turning the attention of the public to its most interesting and important concern. Whatever success may hereafter attend agricultural journals will be and ought to be attributed to them in a great degree—but the expense of postage—the difference in the modes of cultivation in Maryland and New York, render these interesting papers of less value with us, than their intrinsic merits would seem to promise. We want a New England agricultural newspaper. It should be centrally placed—and we ask is there any place more convenient than the Metropolis of New England? We are not citizens of the new city of Boston—we have no local prejudices—but we think that the agricultural societies of Maine, New Hampshire, Vermont, Rhode Island, Connecticut and Massachusetts, the cultivation, soil, climate and habits of which are very similar, (taken in a general view) can find no place more convenient for the communication, and dissemination of the experiments, essays and official papers of their sever-

al societies, and individuals of these states can as conveniently communicate with the Editor of a paper at Boston as with one at a distance in his own state.

Having made these remarks favorable to the new paper just published in Boston, we think it proper to add, that we have no connection whatever with the journal, but we believe the Proprietor, and Mr. Fessenden the Editor, perfectly competent to the undertaking, and that with suitable patronage they will fulfil all the just expectations of the agricultural public.

Without such aids both by way of subscription and of communication on the subject of agriculture, this, and every other such undertaking must necessarily fail—with them, they must succeed. Nothing in New England ever failed, to which she put forth her force with perfect good will.

We are happy to remark, that a respectable paper edited at Plymouth, called the "Old Colony Memorial," devotes a part of its pages to agriculture. A writer in that paper with the signature of "Monnet" asks, "is there no method of staying the ravages of the worm—that is devastating our grass and our corn-fields? What is their history? Is their production or their progress in any way connected with the excessive dryness of the season? Why have they a singular distaste for shade or moisture, leaving a verdant circle round every tree, and making an exact line of demarcation between meadows and upland?"

While we must commend the spirit of inquiry and the desire of improvement and of obviating existing evils which check the labors of the farmer discovered by this querist, the writer of these queries will we are convinced excuse us, for expressing our regret, that he did not give us more precise descriptions of the insect which has proved to be thus injurious. If he has ascertained, that it was a worm, which produced this devastation, he might have described its length, its color, and its first appearance, and duration. Is it the same worm, which attacks the grass, and the corn? A worm, which should destroy or injure Indian corn in August, must be an important enemy, and should be described. Let us intreat our farming brethren when they meet with such an insect to preserve a few of them in phials, that they may be examined by naturalists. A FARMER.

Roxbury, Sept. 3d.

LATEST FROM EUROPE.

London papers have been received at this port, by the ship Champion, which bring dates from that place as late as July 31. They contain little matter of interest. Tranquillity appears to be in a great measure restored to Spain, and the national militia, who had been encamped in Madrid from the 1st to the 17th of July, broke up at the last mentioned date, and retired to their homes. It is reported, however, that two divisions of French troops had crossed the frontier, and entered the Spanish territory. It is thought that these movements will serve to unite the Spaniards in favor of the popular cause. The French soldiers too, it is said, have expressed an unwillingness to oppose the progress of freedom in Spain.

The Greeks appear to be stemming the torrent of oppression with some prospect of eventual success in the acquisition of freedom. They are said to have burnt, on the 22d of June, the Turkish admiral's ship, and two others, and it is stated that the Capt. Pacha, who commanded at Scio, during the infliction of the barbarities which have desolated that island, has lost his life by the fire, which consumed his ship. The Greeks promise their troops lands sequestered from the Turks.

The distress of the Irish for want of food appears to be but little if in any degree mitigated.

The British Parliament has made an appropriation for publishing by authority, a uniform and regular edition of British History. It is expected to cost about 9000 dollars a year.

The fever in New York continues to prevail, notwithstanding the removal of the inhabitants from the quarter in which the disease made its first appearance. On the 30th Aug. were reported 4 new cases—31st, 3—Sept. 1st, 4—2d, 4—3d, 6. A very considerable part of the population has left the city.

LAW OF PATENTS.

CHARLES EWER, No. 51, Cornhill, has just published, price \$3.50, bound,

AN ESSAY ON THE LAW OF PATENTS FOR NEW INVENTIONS. BY THOMAS GREEN FESSENDEN, Counsellor at Law.

"As the West Indies had never been discovered, without the discovery of the Mariner's Needle; so it cannot seem strange, if Science be no farther developed, if the Art itself of Invention and Discovery be passed over."—BACON.

The second edition, with large additions, corrected and improved by the author.

RECOMMENDATIONS.

EXTRACTS FROM LETTERS TO THE AUTHOR.

Salem, Sept. 4, 1821.

SIR—I have examined your MS. on the Law of Patents with as much care as my engagements would permit, and I have no hesitation in expressing my opinion, that the work will be highly useful to all persons who are engaged in obtaining patents, or in vindicating them in Courts of Justice. The manuscript contains a collection of all the cases, on the subject of Patents, within my knowledge; and the principles contained in them are detailed with accuracy and fullness in the Summary, at the conclusion. I know of no work so comprehensive as yours on this subject; and it may be relied on as a safe guide. I hope you will receive encouragement sufficient to justify the publication, which I should think would be profitable as well as extensively useful. JOSEPH STORY.

Thomas G. Fessenden, Esq.

Boston, September 25, 1821.

SIR—We have looked over the manuscript of the second edition of your publication on the Law of Patents. This edition is a great improvement on the first, and we think it will be a valuable and useful book to the profession, as it contains the statutes, and states we believe accurately, all, or nearly all the decisions, which have been made on a branch of the law, daily growing more interesting and important. WM. PRESCOTT, Thomas G. Fessenden, Esq. D. WEBSTER.

Boston, September 27, 1821.

SIR—The new edition of your Essay on Patent-Law, which I have taken some time to examine, is a very improved work. More ample materials, furnished to your hands, by decisions, subsequent to your former edition, have enabled you to present to the public, and the bar a more minute analysis, as well as a more comprehensive view of this branch of law than has yet appeared in England or in this country. Your method of arranging all the decisions, in the order of an analytical digest of the several requirements and provisions of our statutes for granting patents, puts the lawyer at once in possession of the judicial construction of the statutes; while your synthetic summary, far more extended and comprehensive than in the former edition, places within reach of the mechanic a sure means of judging whether his invention is a fit subject for a Patent; what is required of him by the statute in order to obtain his Patent; and what provisions are enacted for securing to himself and heirs his meritorious privilege. I cannot conclude without wishing you the success your labors surely deserve. GEO. SULLIVAN.

Thomas G. Fessenden, Esq.

SUBSCRIBERS TO THE NEW ENGLAND FARMER who wish to be considered as paying in advance for the first Vol. must forward us \$2.50 on or before the first day of October next. All who neglect paying at that time will be charged \$3. We give this seasonable notice that none may complain, as this rule will be strictly adhered to. Sept. 7

HOME.

Home! 'tis the name of all that sweetens life,
It speaks the warm affection of a wife;
The lisping babe that prattles on the knee,
In all the playful grace of infancy;
The spot where fond parental love may trace
The glowing virtues of an infant race;
Oh, 'tis a word of more than magic spell,
Whose sacred power the wanderer best can tell.
He who long distant from his native land,
Feels at the name of home his soul expand;
Whether as patriot, husband, father, friend,
To that dear point his thoughts, his wishes bend;
And still he owns, where'er his footsteps roam,
Life's choicest blessings centre all at home.

From the *Connecticut Agricultural Almanack*.

THE FARMER'S CREED.

Let this be held the Farmer's Creed—
For stock, seek out the choicest breed;
In peace and plenty let them feed;
Your land sow with the best of seed;
Let it not dung nor dressing need;
Inclose, plough, reap, with care and speed,
And you will soon be rich indeed.

From the Old Colony Memorial.

To the Editor.—Sir,

In your last paper, a correspondent inquires, "from whence came the sweet corn, and at what time was it introduced here?"

Of the natural history of the *sweet corn*, it is presumed, that, with all the other species of the Indian corn, it is indigenous to America. Of this particular species, nothing was known in this section of the country (if in New England) before 1779. In that year an expedition under the command of General Sullivan, was sent against the *Six nations of Indians*, inhabiting on the borders of the Susquehannah. Poor's brigade made a part of that expedition. A gentleman from this place,* then an officer in that brigade, on his return, after the expedition, brought some ears of that corn.† That was the first of the species ever seen here, and has, since that time, been more and more diffused; and I believe within a few years only, has been generally and extensively cultivated for culinary purposes. The species has undergone some change since it was first introduced—then the core was a bright crimson, and after being boiled, and the corn taken off, if the core was laid in contact with any linen (the table cloth or a napkin,) it communicated an indelible stain. This inconvenience has disappeared. This species also, like what is distinguished by the appellation of southern or flat corn, by repeated planting here, assimilates it to our local corn—for a number of years I was careful in selecting the largest and fairest ears for seed, until it grew nearly as large and fair as the common corn, and at the same time lost much of its peculiar qualities, *softness* and *sweetness*: and I concluded it would, in process of cultivation, become assimilated to the common corn of New England, although I accidentally discovered that the ears which were produced on the suckers (and it is very much disposed to sucker,) were smaller, much more shrivelled, and in appear-

ance perfectly similar to the corn which I first remembered to have seen. I then selected some of the ears from the suckers, which were sufficiently ripe, and served for seed, and found, that on the next year's planting, I had reproduced corn, at the least ten years' retrograde; and have since then annually saved a portion of seed in that mode. The fact will be obvious to any one who is in the practice of gathering the corn, that the ears which are produced on the suckers, though small, retain the milk longer, and are suitable for the table longer, than those that are produced on the leading stalks. If these hints can give any satisfaction to your querist, or can, in your opinion, be the occasion of eliciting any further information on the natural history of sweet corn, you will please give them a place in your vehicle of agricultural and historical information. Yours,

PLYMOTHEUS.

MISCELLANEOUS.

THOUGHTS ON WAR.

It is wonderful with what coolness and indifference the greater part of mankind see war commenced. Those who hear of it at a distance or read of it in books, but have never presented its evils to their minds, consider it as little more than a splendid game, a proclamation, an army, a battle and a triumph. Some indeed must perish in the most successful field, but they die upon the bed of honor—resign their lives amidst the joys of conquest, and filled with their country's glory, smile in death. The life of a modern soldier is ill represented in heroic fiction. War has means of destruction more formidable than the cannon and the sword. Of the thousands and tens of thousands that perish in war, a small part feel the stroke of an enemy. The greater number languish in ships, in tents or hospitals, amidst damps and putrefactions; pale, torpid, spiritless and hopeless, gasping and groaning, unpitied among men made obdurate by long continuance of hopeless misery, and at last are buried in pits, or heaved into the ocean, without notice and without remembrance. By inconvenient encampments, and unwholesome stations, where courage is useless, and enterprise impracticable, fleets are silently dispeopled, and armies sluggishly melted away. Thus is a people gradually exhausted, for the most part with little effect. The wars of civilized nations make very slow changes in the system of empire; the public perceive scarcely any alteration but an increase of debt, and the few individuals who are benefitted, are not supposed to have the clearest right to their advantages. If he that shared the danger enjoyed the profit, and after bleeding in the battle grew rich by the victory, he might show his gains without envy. But at the conclusion of a ten year's war how are we recompensed for the death of multitudes, and the expense of millions, but by contemplating the sudden glories of paymasters and agents, contractors and commissaries, whose equipages shine like meteors, and whose palaces rise like exhalations. These are the men, who, without virtue, labor or hazard, are growing rich as their country is impoverished. They rejoice when obstinacy or ambition adds another year to slaughter and desolation, and laugh from their desks at bravery and science, while they are adding figure to

figure and cypher to cypher, hoping for a new contract from a new armament, and computing the profits of a siege or a tempest.

Dr. Johnson.

He who goes to bed in anger has the devil for a bed fellow.

An antiquary has been said to esteem every thing as Dutchmen do cheese, the better for being mouldy.

A good character is the greatest of temporal blessings, with the exception of a good conscience; and good health stands next on the list of sublunary enjoyments.

Knaves live upon fools as naturally as spiders prey upon flies. But there is nothing worth being dishonest. Crimes, though secret, are never secure, for Providence has set up racks and gibbets in the consciences of transgressors, and they all carry Cain's fears about them. He that deserves punishment, expects it, and is ever in apprehensions until detected; his very sleep is painful, and his life a terror.

How sweet in the moment of affliction is the exercise of the social affections! they are the balm which, mingled in the bitter cup of grief, allays its harshness, and subdues its venom. No human being can be perfectly miserable so long as he can enjoy the sympathy of one kindred soul; and even when that is denied, the Christian knows there is an ear open to the sorrowful sighings of every afflicted heart.

THE PROGRESS OF LOVE.

Love makes its way insensibly through respect and gratitude, as a flower, which in order to blow, opens the slight texture in which it is enfolded.

NATURE'S MISTAKES.

Dame nature is liable to errors as well as other gentle folks—although, in general way, it must be acknowledged that the old lady is pretty correct in her conduct, yet she sometimes takes steps, which in demi-reps would be deemed very disreputable. She makes calves with two heads, snakes with two bodies, &c. and these are called *lusi natura*, or amusements of nature. But her greatest error lies in the mode in which she forms some people's heads and hearts, by making their heads soft and their hearts hard, although good workmanship requires exactly the reverse.

Age and love associate not; if they are ever allied, the firmer the friendship, the more fatal is its termination; and an old man, like a spider, can never make love, without beating his own death-watch.

[NOTE.—It may not be generally known that the male spider is supplied with a little bladder, somewhat similar to a drum, and that tickling noise which has been termed the death-watch, is nothing more than the sound he makes upon this little apparatus in order to serenade and allure his mistress.]—*Portland Gazette*.

Joking Dialogue.—Would you believe it? Mr. B. tells me he has written a comedy, but I suppose he was joking. By no means, for I have seen it, and I assure you there is no joke in it.

* Captain Richard Bagnal, then a Lieutenant.

† There called the *Papoon corn*, probably from its tenderness and sweetness made the food of children.

NEW ENGLAND FARMER.

Vol. I.

BOSTON, SATURDAY, SEPTEMBER 11, 1822.

No. 7.

CONSIDERATIONS ON THE NECESSITY OF ESTABLISHING AN AGRICULTURAL COLLEGE,

and having more of the children of wealthy citizens educated for the

PROFESSION OF FARMING.

(Continued from p. 42.)

By the infallible oracles of divine inspiration we are taught, that no man can obtain a good character as a christian, unless he denies himself, takes up his cross—cuts off a right hand, or pulls out an eye, if necessary for his advancement to perfection—Figurative expressions, denoting the extremes of self-denial, fortitude and voluntary suffering. The same doctrine may, with a qualified propriety, be addressed to those who aim at distinction in any of the professions of civil life. Whatever may be the genius or natural powers, there must be the *labor improbus*, hard labor, strong exertions, struggles against improper propensities, a rigid observance of rules, a radical extermination of evil habits, scrupulous improvement of time, an unwavering perseverance, and a judicious exercise of a well disciplined reason in the selection of means or the attainment of the objects to be achieved. A generous youth, anxious about his fate, waked from his reveries, and adverting to his lost or misapplied time, will often exclaim with the poet,

"The bell strikes one!—How much is to be done!
My hopes and fears start up alarm'd,
And o'er life's narrow verge look down—
On what?"

and redouble his exertions so to improve his natural powers as that they may be displayed in manner the most eminent in the character he has chosen to appear in on the stage of life; diffuse to others the greatest good, and procure for himself the greatest applause, with an approving conscience.

These observations are made to wipe away all flimsy objections which that foolish womanish tenderness, and that contemptible pride, which are the usual concomitants of an imbecility of intellect, may raise against the discipline and labor that will be required by the institution proposed to be created.

But perhaps our young gentlemen, or their polished sympathising parents, will be afraid that working like a farmer may spoil the delicate complexion of their hands, and destroy that mark which they are to be distinguished from the vulgar. What a ridiculous notion of merit! What contrast to the opinions and practice of the most admired eras of antiquity, when man rose to an unparalleled grandeur! When Cincinnatus, after having, as dictator of the proudest and most powerful nation on earth, performed such deeds as have shed a superlative lustre of glory about his name, and transmitted it as an object of supreme admiration through every age, returned to the plough, and resumed his occupation as a farmer for a living.

"In ancient time, the sacred plough employ'd
The kings and awful fathers of mankind,
And some, compar'd with whom your insect tribes
Are but the beings of a summer's day,

Have held the scale of empire, rul'd the storm
Of mighty war, then with unworldly hand,
In claiming little delicacies, seiz'd
The plough, and greatly independent liv'd."

As in our civil institutions we have nearly emancipated ourselves from all the trammels bequeathed by the ages of barbarism, and with which the nations of Europe yet remain shackled, so let us also discard such of their customs, and fashions, and rules of taste, as have not a spark of reason to vindicate them; but on the contrary, must, on the slightest examination, appear notoriously derogatory to that independence and superiority of character of which it is the glory of the Americans to be able to boast.

All kinds of useful labor and hardihood, connected with an unimpeachable morality, and a decorous deportment, deserve respect and honorable treatment; and wherever the contrary is customary, a corruption of manners is indicated, which, so far from descending to emulate, we should treat with the proud scorn of conscious superiority.

Every thing in man of an effeminate cast must detract from his character, and if voluntarily acquired, or cherished as a matter of value, deserves contempt. Such is the lady-like lily hand of a *petit maitre*; which is about as proper an object to be proud of as the long nails of the Asiatic beaux, cherished and guarded with idolatrous care, to shew that they are above the rank of laborers, and for the preservation of which, elegant ivory tubes are worn at the ends of their fingers.

A number of considerations not capable of enumeration, besides those already anticipated, crowd on the reflecting mind in favor of an institution, especially in our country, that shall have for its primary object, instruction in theoretic and practical agriculture. But it may be asked, on the introduction of the subject, why have not institutions of this kind been formed and patronized in older countries, especially in England, where agriculture has so much engaged the attention of its first characters, and where it has been carried to such a height of perfection? The reason is obvious. In most foreign countries the fee of the soil is generally in the gentry, who besides their tenancies, have extensive farms under their immediate superintendence; who make farming in some measure a business, and who can afford to make experiments and communicate such as result in improvements of consequence, to those, who, pursuing a steady course, known to be safe and profitable, will not hazard a departure from it without such a demonstration. Such improvements are moreover communicated to their societies or boards of agriculture, by which they are published for the benefit of the public, and thus constantly reciprocated among all who are engaged in its interests.—The sons of such gentlemen farmers, from the practice of which they are the constant witnesses, can hardly fail of acquiring a proficiency in the knowledge of agriculture, so far at least as to qualify them for its superintendence. Thus, then, every landlord's farm, becomes to a certain degree, a school of

practical agriculture, where experiments are constantly made, by wealthy, scientific, and practical men, to ascertain the best methods of profitable culture; where the knowledge of it is transmitted as a family inheritance, and sheds its meliorating influence immediately over a wide circle of tenantry, and remotely over the kingdom at large. And even in those countries there are not wanting some arrangements in these academical establishments for teaching the scientific parts, if not the actual practice of agriculture. But here circumstances are widely different. With but very few exceptions, we have no landlords and fewer still of that class who turn their attention to farming. It is the glory of our country, that with such rare exceptions, every farmer is the absolute, independent lord of his own territory, little as it may be, and works it with his own hands, and by his own hired laborers: His children are his pupils, whom he teaches from their infancy the mysteries of his calling; but the meanness of his circumstances, and his habitual prudence will not permit him to hazard experiments for improvements. What he knows of it as practised by his father, will be known by his children, and they will probably during their lives, follow his track without deviation. Under such circumstances, agriculture must remain at a stand, although, like other arts, its past progressive improvements, warrant the presumption that to its future no limits can be assigned.

The Agricultural Societies, organized and brought into action of late, operate principally by the stimulus of emulation; and the good that they are calculated to do, and will unquestionably do, if continued with the spirit with which they have started, and with the improvements which time and experience will indicate, must be great, very great, in a department of business which of all others is the most important to our country. But it is evident that the good derived from them is conveyed through one channel, broad indeed and deep, and having attached to it numerous ramifications; still there may be others leading to the same port, and as essential to the effectual promotion of our national prosperity. The institution now proposed will not be their rival, but rather a co-operator. Its essential difference of character will be, that, availing itself of all the improvements that have been made, and are constantly making, in the science and practice of agriculture, it will be a school where they will be taught in that perfection to which they have been carried by all those variegated means, and by all the experience of every nation, and every age, since men first emerged from a state of barbarism. It is intended not so much to give instruction to farmers as to make farmers from the other classes of society, which are stocked with such a superfluity of members that hordes of them must otherwise remain useless, or worse than useless to the community—and while this is doing it will shed a light over the profession, that may be greatly useful, even, to those who are most eminent in it.

The farming department in America cannot be overstocked, at least for centuries before us,

so wide, so various, so boundless is the field, that imagination cannot grasp the population sufficient to fill it; and it is only in proportion as the population grows will be the substantial wealth, the grandeur, and the happiness of our country. It is the only solid foundation on which our national prosperity can be erected, and therefore the object of all others, that ought first and chiefly to engage the attention of government. No rational scheme for its advancement can therefore, consistent with that wisdom which characterises true statesmen, be treated otherwise than with an impartial and a deliberate investigation of its merits; and if found eligible, whatever apparent difficulties may be in the way, its adoption must and will be effected.

It is therefore true policy to draw into this field as many as possible, especially of young men, qualified for it by a suitable education, and possessed of a capital sufficient to conduct their affairs to advantage. But how is such an acquisition to be effected?

At present there is no doubt that there are numbers of men of fortune in our states, and many of them large owners of lands, who would wish to qualify, as farmers, at least some of their sons, and give them suitable establishments as such, but are deterred from it by such considerations as the following.

Success in every profession or calling depends on a perfect knowledge of it.—Such knowledge cannot be obtained without actual application for its attainment as a student or apprentice for a competent time.—The profession of a farmer, no less than that of a lawyer, a physician, a divine, a manufacturer, or of any of the mechanic arts, cannot be duly acquired without such application.—For any one to undertake a business with which he is unacquainted, or rather for which he has not been regularly educated, is the height of folly, as it must in all probability eventually ruin him.—In every kind of business there will be sharp competitions, and those who are the most adroit and skilful in it, will, with equal means and industry, make the most by it, and those who have not a competent knowledge of it must suffer in its pursuit.

Now, how are the sons of wealthy gentlemen of other professions to acquire such knowledge of agriculture? At present there is no other way than to put them out to serve as apprentices to farmers. To this there are many objections. From their previous education they will not be disposed to submit to the necessary discipline, and their masters will not have it in their power to enforce it.—They may be associated with laborers whose manners will contaminate theirs.—They will probably be destitute of all society by which they might be stimulated to further advances in their previous studies and progress in refinement.—Released from adequate restraints, they may be enticed, by profligate companions, into low-bred practices, and contract disgraceful and ruinous habits. And, after all, in the best situations, they could learn little more than the business of a farmer in its most ordinary state.

For all this there is no remedy but an institution like that which is now proposed, the happy tendency of which, when once established, will beyond all doubt be abundantly demonstrated as soon as it shall be completely carried into operation.

It will make agricultural pursuits more fashionable, and engage in them the noblest spring of human activity, the ambition to shine pre-eminently in a sphere of usefulness, of the most brilliant character, and the widest extended magnitude.

(TO BE CONTINUED.)

PREPARING FLAX.

We esteem ourselves fortunate in being permitted to lay before our readers the following extracts from a correspondence between His Excellency the Governor of Connecticut, and S. W. Pomeroy, Esq. of this State. The subject is of great importance, and if it continues to engage the attention of men of mind, influence, character and standing, its discussion may be the means of giving a new staple to New England of little if any less importance than cotton or tobacco to Southern sections of the Union.—ED. N. E. F.

Litchfield, Conn. June 25, 1822.

DEAR SIR,

I have read with great satisfaction your Essay on the Cultivation of Flax, and consider it as the best I have seen; what we now want, is a discovery of the best means of extracting the glutinous matter, and decomposing the woody fibre, without fixing the color, so as to render the process of bleaching, difficult and expensive. The common process of rotting in the air, we know will never give us good Flax, and the process of water rotting will not be practised by our people generally; it being a disagreeable and unhealthy business to those employed in it, and besides poisonous to our streams of water.

The extension of our Flax culture, will, in my opinion, greatly depend upon our success in finding out a mode by which common farmers can extract the gluten, and weaken the woody fibre, so as to render Flax, after being stripped of its seeds, manageable by such operations or machines, as can be introduced into common use.

The practical question is therefore, does there, or does there not exist in nature, a *cheap and common solvent*, which can be applied to Flax, *in mass*, by operative farmers?

You live in a part of our country which is deeply interested in this question. You, more probably than any person with whom I am acquainted, can discover this *solvent*, (if it exist,) and the public attention having been much attracted to your publication, your recommendation would have a most extensive and salutary influence.

I therefore take the liberty to request your particular attention to this interesting subject. I feel confident that *the thing desired can be done*, but I cannot command the means of making the necessary experiments: I can only suggest hints, which may be useful.

Flax may, in mass, be subjected to the action of steam. This may of itself extract the glutinous matter, and sufficiently weaken the woody fibre, after being merely dried in the air: Will it fix the color of the plant? The Flax, before steaming, may be soaked in weak lye, with or without lime, or lime water, and with, or without soap suds, and urine. Near the coast, salt water, with and without the combinations before mentioned, may be useful.

Any of the chymical processes of bleaching, may, for ought I can perceive, be as well applied to Flax in mass, before it is broken and

dressed, as afterwards. A question must however arise, respecting the expences of all the processes, compared with the value of the Flax when it has been prepared as an article of commerce.

I send you samples of Flax, which, as I understand, were prepared in Hill & Bundy's Machine. The *yellow* is from Flax which had not been rotted; and the *white* is the same article after being bleached, by means of soap suds, and a weak solution of muriatic acid.

Your friend and obedient servant,

OLIVER WOLCOTT.

S. W. POMEROY, Esq.

Brighton, 14th July, 1822.

DEAR SIR,

Your highly valued favor of 29th ult. with samples of *Flax*, prepared in Hill & Bundy's machines, came to hand a few days since.

Soon after the publication of the "Essay on Flax Husbandry," the Board of Trustees of the Massachusetts Agricultural Society, promulgated the offer of liberal rewards for the best experiments on the preparation of Flax, by *boiling steaming*, or *any other* than the usual mode. Though the quantity required was only 75 lb. and the period for receiving it continued till the middle of January, none was exhibited, and as the competition was not confined to local bounds, there is reason to believe that the publication of the invention by Messrs. Dey & McDonald, of a machine that would supersede the necessity of *any* preparation, and its successful operation confidently relied on, had an effect to paralyze all efforts of the kind.

From the best information I was able to collect, before my Essay went to press, I felt strong conviction that the machines of Hill & Bundy could not be made extensively useful in this country; and if their neglect in G. Britain except for employing infirm people and children in poor houses and cottages, was not sufficient to deter me, I have since received intelligence from a source entitled to confidence, that places the question beyond all doubt. An acquaintance with a gentleman of respectability, lately arrived from England, has furnished interesting facts connected with the present subject, some of which it may be well to state before I attempt a reply to your queries. This person has been extensively engaged in the manufacture of linen machinery at Leeds. He says that "spinning by hand is mostly abandoned; that last year about twenty thousand spindles were in operation at Leeds and its vicinity, which worked up about a thousand tons of flax for fabrics, from the coarsest sort, to those worth three shillings sterling per yard, at as cheap a rate (calculating length and breadth) as cotton is spun, and from 12 to 18 prepared in the usual way;—that no confidence is placed in the general utility of Hill & Bundy's machines—the price of dressing and bleaching by them being sixpence sterling per pound—about equal to the cost of the whole material as now used;—that the advantage of working bleached flax is of no great importance since the discovery and improvements in the process of bleaching with the *oxy muriate of lime*, which *linen*, even from dew rotted flax, is bleached nearly as cheap as cotton, and, if judiciously applied, without the least danger of injury to the article;"—it should also be considered that cloth made from *bleached* flax must be submitted

a similar process before it is made up for market.

I coincide in the opinion you have expressed, Sir, that "the extension of flax culture will greatly depend upon finding out a mode by which common farmers can extract the glutinous matter and weaken the woody fibre, so as to render the flax manageable by such operations or machines as can be introduced into common use," and sincerely regret my inability to adduce facts in answer to your question. Does there or does there not exist in nature a cheap and common solvent which can be applied to flax, in mass, by operative farmers? Feeling, like yourself, confident that "the thing desired can be done," and, although possessed of no data derived from experiments, as you have desired my opinion on the subject I shall submit a few remarks which will pass for what they may be worth.

The candor and liberality manifested by Mr. Dey, and the spirit with which he pursues his subject, are to be admired; but admitting that is most sanguine expectations will be realized in the successful operation of his machines for separating the fibre or harle from the stem of the plant, yet the very important process of leaching it from the glutinous matter remains to be performed, and the question occurs, "can it this be done, in the large way, as cheap, and with much less hazard by common farmers with the raw stem, as with the fibres after they are separated?" I am inclined to believe that it can. The only objection is the expense and inconvenience of managing a more bulky article; but will not the dressed flax require equal labor in dividing it into minute parcels for the leaching process, and uncommon care in banding and drying to prevent immense waste? By applying the solvent to the stem, it is reasonable to suppose that the "woody fibre" would be weakened to such a degree that much less power will be required to separate it, and of course less complicated and expensive machines.

It is not probable that the end we are seeking will be efficiently attained without the aid of heat. Steam even from pure water is a most powerful solvent; and I have great faith that with a proper menstruum, it may be successfully applied by common farmers. I am led to this conclusion by its operation with a perfectly simple apparatus in washing clothes—by far the readiest and most economical improvement yet discovered to disarm washing day of its terrors. It consists of a pot or boiler, with a close cover, into which a tin or leaden tube is inserted, and a tub or box with a similar cover. The clothes, after being wet and a little soap rubbed on the most soiled parts of them, are laid upon slats or helves in the tub or box, the tube is then connected with it, and the boiler nearly filled with water mixed with a weak solution of potash or ley from the leach tub, a fire is put under the boiler late in the afternoon, it boils during the evening and is left simmering till morning, when the clothes are taken out; and they must have been very foul to require any more labor than rinsing once or twice to make them perfectly clean. Now this process is managed by common house maids! What is to prevent them, the wives and daughters of farmers and even farmers themselves from attending to a similar process on a larger scale? I apprehend no danger from steam, in fixing any stain or color, that may be communicated by the plant.

We will now inquire for a menstruum within the reach of "common farmers," and it will not be necessary for the present object to combine the bleaching process, though it may follow in a considerable degree. I would here observe that there was an important omission in copying my Essay for the press, in quoting from the transactions of the Swedish Academy, of the application of birch ashes spread between the layers of flax before the salt water was turned on for boiling. Should such a process be found beneficial, sea water can be easily and cheaply imitated in the interior country.

Mr. Dey asserts that the materials he has discovered for cleaning and bleaching flax dressed by his machine, "are abundant in every farmer's house." I shall be much mistaken in my conjectures if ashes, salt, and perhaps lime, with vegetable acid or sour milk are not the principal constituents of his secret!

The substances used in bleaching will, I believe, either combined or separate, afford the best solvent within our knowledge, for the object in view; and acids are considered of primary and indispensable importance; they were formerly produced by the fermentation of rye meal or bran—sour milk was also used as extensively as it could be obtained. But it has been found that a weak solution of sulphuric acid answers the same purpose—is more convenient and much cheaper. Oil of vitriol in a highly concentrated state is now manufactured in Boston, and sold at not more than eight cents per pound—one pound of which is said to be sufficient to acidulate two hundred gallons of water. It is probable however that five pounds to that quantity of water, if thoroughly mixed, would not injure the material and accelerate the process.

When we reflect upon the rationale of the preparation of flax by the usual method of steeping in water, it appears that it is the acid produced by the acetous fermentation that dissolves the glutinous matter; the mere act of fermentation has no other effect than to give motion to the liquid, as has been demonstrated by eminent bleachers in Great Britain when comparing the effect of sulphuric acid with that produced by fermentation. It is true that by steeping, the putrid fermentation which rapidly follows the acetous, hastens the operation and more readily decomposes the woody fibre, but with manifest injury to the material! Now it requires ten or fourteen days to prepare flax by steeping, when done in cool weather as it should be; if this can be effected in half as many hours with sulphuric acid, even with the expense of heat, may it not be the cheapest solvent?

It should be kept in view, that there is a cellular oil in flax, which an alkaline ley destroys; this is apparent from the harshness of linen yarn that has been boiled in it—the decomposition of this oil may be necessary to the completely bleaching of fine goods, but it is important to retain it for sail cloth, as not only rendering it soft and pliable, but as a preservative against mildew. The steam from such ley however, is supposed not to produce that effect.

Whether the *oxi-muriate of lime*, the principal agent now used for bleaching, may be successfully applied as a solvent to the raw stem of flax, can be determined only by experiments; the materials for forming it are abundant and

cheap. A formula I met with forty years ago, requires 60 lbs. of *finely powdered quicklime* and 30 lbs. of *common salt* to be mixed with 140 gallons of water in the receiver; into the distilling vessel is put 30 lbs. of *salt*, with 30 lbs. of *manganese*, which are to be well mixed, and 30 lbs. of oil of vitriol, diluted with the same weight of water, turned on. But I am told that great improvements have been made of late—that it is prepared in the *dry way*, which renders it conveniently portable, and is sold to the bleachers at a very cheap rate.*

Perhaps the simple *muriate of lime* would answer the purpose; in that case the expense would be much lessened, and the operation so simplified as to render it convenient to be used by operative farmers.

I should feel extremely happy, Sir, was it in my power, to institute a course of experiments agreeably to your suggestions, and which your partiality supposes me capable of performing; but a pressure of domestic avocations, together with preparations for an expected absence from home, of some months continuance in the autumn, wholly preclude such attempts. At the same time I beg you to rest assured that I shall always feel ambitious, to the extent of my ability, to co-operate for the promotion of rural economy, with one who has devoted so great a portion of life for the advancement of the substantial interests of his country.

With respectful and sincere attachment,

I remain, Sir, your obedient servant,

S. W. POMEROY

His Ex'y OLIVER WOLCOTT,
Litchfield, Conn.

*The substance of the mode of preparing Bleaching Powder, according to as late an improvement as any we have seen, is as follows:

Oxygenated muriatic acid is capable of forming a compound with calcareous earth, and with the carbonates, strontites, and magnesia, in the dry way, that is, without these earths being either suspended, or dissolved in water; and this is effected merely by bringing the oxygenated muriatic gas into contact with these earths in form of lumps, pieces, powder or paste, or into contact with mixtures of them, with such other bodies in the above forms, as do not impede or hinder their attraction for the acid. It has been found that the oxygenated muriates of lime, and of the earths mentioned above, thus formed, when mixed with water, possess the power of removing color from linen, cotton, and various other vegetable and animal substances, and have been profitably applied for that purpose. See *Repository of Arts*, vol. vii, p. 1, *ser. seriatim*.

If we mistake not, Sir Humphrey Davy, in one of his lectures has intimated that there is danger lest the caustic powers of oxy-muriate of lime should injure the texture of the material to be bleached; and he therefore prefers magnesia as one of the ingredients of bleaching powder to lime. Simple muriate of lime, as recommended by Mr. Pomroy, deserves experiment, and perhaps lime slackened with sea water, or salt in solution with water, would be found useful. Care however is necessary not to apply caustic substances of too great strength, and in every case to thoroughly rinse the goods in pure water after every application of a bleaching substance, of the nature above described.

Ed. N. E. F.

Robbing Gardens.—Several indictments and convictions, of boys and youths, have taken place in various parts of the State, for violations of the statute made to prevent depredations upon orchards, gardens and fruit-yards.—Its penalties are very severe, and yet we are glad that a disposition prevails to enforce it.

Worcester Spy

CATTLE SHOW,

EXHIBITION OF MANUFACTURES, AND
PLOUGHING MATCH,

At Worcester, on Wednesday, September 25, 1872.

The Trustees of the Worcester County Agricultural Society, propose to their fellow citizens a Cattle Show, Ploughing Match, and Exhibition of Manufactures, at Worcester, on WEDNESDAY, the 25th day of September next, at 9 o'clock, A. M.—and they have the pleasure of offering the following liberal Premiums, much increased in amount from the last year:

- For the best Bull, not less than one year old \$15
For the next best 10
For the best Bull Calf, from 4 to 12 months old 6
For the next best 4
For the best Milch Cow, not less than three years old, and from a stock of not less than five Cows kept together 15
For the best Milch Cow, not less than three years old, and from a stock of not less than three Cows kept together 10
For the next best Milch Cow, whether kept alone or with others 6
For the best Heifer from 1 to 3 years old past 6
For the next best 5
For the best Heifer Calf from 1 to 12 months old 5
For the next best 4
For the best pair of Working Oxen, not less than four years old, regard being had to the strength, equality of match, and docility of the cattle, as well as to their size and appearance 15
For the next best 12
For the next best 10
For the next best 5
For the best pair of four years old Steers, not offered for work 10
For the best pair of three years old Steers 8
For the next best 7
For the best pair of two years old Steers 5
For the next best 4
For the best pair of yearling Steers 5
For the next best 4
For the best Ox fitted for slaughter, regard being had to the mode and expense of fattening 15
For the next best 10
For the best Merino Ram, regard being had both to fleece and size 10
For the next best 5
For the best Merino Ewes, not less than four in number 10
For the next best do. 5
For the best two Merino Wethers 5
For the best lot of mixed Merino sheep, not less than five in number, either Ewes or Wethers, regard being had to the quality of fleece for the grade 5
For the best Native Ram 5
For the best Native Ewes, not less than four in number 4
For the best Boar, not less than six months old, nor more than two years and six months old 10
For the best Breeding Sow, not less than one year old 6
For the best weaned Pigs, not less than four in number 4

None of the animals will be entitled to Premiums unless they are wholly the product of the County, excepting, that with a view to encourage the introduction of improved Stock, the Trustees will pay the premiums which may be awarded for Bulls, Rams, and Boars, raised within the State and brought into the County at least four months before the day of Exhibition, upon receiving satisfactory security that they shall be kept for use within the County at least one year next after.

In awarding the Premiums upon all Stock, regard will be had to the manner and expense of raising and keeping. And the owner will be required to give a satisfactory account thereof

to the appropriate Committee on the day of Exhibition—as it is the intention of the Trustees to encourage that Stock, which not only may appear best at the Show, but which, in reference to the cost, is most profitable to the Farmer.

The Trustees with a view to the most liberal encouragement of the Citizens of the County who live remote from the place of Exhibition, propose to increase the rate of compensation for travel to eight cents per mile, to the owners of such animals as obtain premiums, and which are brought or driven more than ten miles, computing from the place from which the animals come to the place of the Show.

No animal for which to any owner one premium shall have been awarded, shall be considered a subject for any future premium of the Society, except it be for qualities different from those for which the former premium was awarded.

Persons intending to offer any species of Stock for premium, must give notice thereof, either by letter, post paid, or by personal application to the Recording Secretary, on or before the 21th of September, (the day preceding the Show) at 9 o'clock in the evening, requesting him to enter his application, so that Tickets for the Pens may be ready by 8 o'clock the next morning. The difficulty of making arrangements for the proper accommodation of the different species of Stock, without such previous notice, renders a strict enforcement of this rule indispensable—and no person will be considered as a competitor, who shall not have made such application for entry, on or before the time above specified.

In all cases where the age of animals is mentioned, the applicant must file his own certificate, or that of some other respectable individual, who personally knows the fact, that they are of the age for which they are entered, and also that they are the product of the County.

DOMESTIC MANUFACTURES.

- To the person or Corporation who shall exhibit the best double set of Machine Cards \$20
The best superfine Broadcloth, dyed in the Wool, not less than six quarters wide, exclusive of the list, and 20 yards in length 15
The best superfine Cassimere, dyed in the wool, not less than three quarters wide, and 20 yards in length 10
The best Carpeting four quarters wide, and not less than 30 yards in length 15
The best Carpeting three quarters wide, and not less than 30 yards in length 10
The best sole Leather not less than 100 lbs. 10
The best manufactured Calf-Skins not less than 12 in number 6
The best manufactured Morocco Leather of Goat Skins, not less than six in number 6

TO THE PERSON WHO SHALL EXHIBIT OF HOUSEHOLD MANUFACTURE.

- The best Woollen Cloth, not less than three quarters wide, and 20 yards in length \$5
The next best 5
The best Flannel not less than 7-8ths wide and 20 yards in length 10
The next best 5
The best Spitting Cloth of linen warp and tow or cotton filling 7-8ths wide and 20 yds. in length, and bleached 5
The next best 5
The best Woollen Coverlid not less than 2 1-2 yards wide 4
The best Linen or tow Diaper five quarters wide and not less than 20 yards in length 8
The best Linen or tow Diaper four quarters wide, and not less than 20 yards in length 5

The best Woollen half stockings for men, not less than two pairs

The best specimen of Sewing Silk of assorted colors, and not less than two pounds in quantity 1

The best Butter not less than 30 lbs.

The next best

The next best

The best lot of Cheese not less than 100 lbs. of the manufacture of the same person 1

The next best

[The specimens of Butter and Cheese must be accompanied with a particular account of the manner in which the same was made and preserved, and the butter must be exhibited in plain unpainted boxes or tubs.]

Every article of manufacture offered for Premium, must be entered with the Recording Secretary, and delivered to the person appointed to receive them, before 11 o'clock in the forenoon of the day preceding the Exhibition. And all manufactures, when presented, must have a private mark, and any public or known mark must be completely concealed, so as not to be seen or known by the Committee—no must the Proprietors be present when they are examined; and the goods must not be removed until 5 o'clock of the day of Exhibition, unless by permission of the Committee of Arrangements: in default of either of which requisitions, the articles will not be entitled to consideration or premium.

PLOUGHING MATCH.

The Trustees also propose to unite with the Cattle Show, a PLOUGHING MATCH, on the same day, and to give Premiums to the owners and Ploughmen of the four Ploughs, which shall be adjudged by a competent Committee, to have performed the best work with the least expense of labor, upon a plot of ground not exceeding one fourth of an acre, with a Plough drawn by one or more yoke of Oxen. In the three first cases if there be no driver, both sums for ploughman and driver to be awarded to the Ploughman.

First Plough,	\$10	Third Plough,	\$6
Ploughman,	5	Ploughman,	3
Driver,	3	Driver,	1
Second Plough,	8	Fourth Plough,	4
Ploughman,	4	Ploughman,	2
Driver,	2		

As the great object of this part of the Exhibition is to excite emulation in the use and construction of the most important instrument of Agriculture, the Plough, the competitors in the Ploughing Match must own their respective Ploughs and Cattle, and the Ploughman, if he be not the owner, must be a man employed on the owner's farm. Those persons who design to become competitors must give notice in writing to the Recording Secretary, on or before the 15th day of September next, that suitable ground may be obtained, the proper number of Lots measured and marked out, and the requisite arrangements made for the occasion. The Ploughs must be on the ground designated, ready to start together precisely at 9 o'clock, A. M. as this will be the first public business of the day attended to. Such arrangements will be made that the Cattle engaged in the Ploughing Match, and which may also be entered for premiums as working oxen, may have opportunity to be well refreshed before they are subjected to examination and trial. Cattle or Ploughs, which have heretofore obtained a premium in the Ploughing Match, will not be entitled again to a premium unless for excelling in a higher degree.

Competitors for Premiums of every description will be held to a rigid compliance with the foregoing Rules, as well as such other Rules and Regulations as shall be published by the respective committees of Premiums hereafter to be appointed and the Committee of Arrangements for the occasion.

In cases where, for want of competition, the claimants upon a literal construction of these proposals might be entitled to premiums, the Trustees shall be at liberty to reject the claim, unless the animal, or manufactured article, is of superior quality and value.

No person will be allowed two premiums, as for the best and next best of an animal or article of the same description, it being the object of the Trustees to encourage competition, by distributing premiums, as much as possible, among the deserving; and no owner of any number of premium animals will be entitled to more than one allowance for travel.

From the premiums awarded there will be discounted twenty-five per cent. in the payment to those persons who, at the time, are not Members of the Society; and no premium will be awarded for animals to any person who, at the time, is not the owner, nor for manufactured articles, unless they were manufactured within the County—and no premium will be paid to any person who is not an inhabitant of the County.

Premiums will be paid within 30 days after they are awarded; but if not demanded within four months, they will be considered relinquished, and the amount will be added to the funds of the Society.

LEVI LINCOLN,	} Committee of Premiums.

FOR THE NEW ENGLAND FARMER

POTATOES.

Having heard many different opinions respecting the best method of preparing seed potatoes for planting, some saying that it is best to plant large ones whole, others that small ones are equally as good, while others say they will produce most to cut them in pieces, with one eye in each piece, or only eyes cut out of large potatoes they say will do well, and lastly some affirm that the parings taken off when preparing them for the pot will produce a good crop.

About the beginning of May, 1821, I prepared a small piece of land, on which I planted seven rows with four hills in each row, as follows:—

- 1st Row—One potatoe weighing about 7 oz. in each hill.
- 2d—One of the same size, cut in four pieces, in each hill.
- 3d—Three whole potatoes, weighing each 2 oz. in each hill.
- 4th—Six of the same size cut into quarters, and six quarters placed in each hill.
- 5th—Some middling large potatoes cut into pieces, with one eye in each piece, and five pieces put in each hill.
- 6th—Cut 24 eyes out of large potatoes, and put six in a hill.

7th—Put a small handful of parings in each hill.

The quality of the land was equal, not rich, no manure was applied, the rows all came up well, and were all hoed and treated alike thro' the summer.

About the beginning of October I had them taken up, and the produce was as follows:

The 1st row yielded	17 lb. 7 oz.
2d do.	22 7
3d do.	10 7
4th do.	11 7
5th do.	16 11
6th do.	11 00
7th do.	10 00

The hills stood three feet distant each way, which makes 4840 in an acre. Allowing a bushel of potatoes to weigh 60 lbs. the products of the different rows would be nearly as follows:

1st row, 350 bushels per acre.	
2d row, 450	5th row, 339
3d row, 210	6th row, 222
4th row, 307	7th row, 202

It is evident, from the above statement, that large potatoes are much better for seed than small ones, and that it is better to cut them than to plant them whole.

About the same time I took a quantity of middling large potatoes, and cut off the but and top ends from each, and cut the middle pieces into quarters, and planted a row with butts, another row with tops, and the third with middles, and placed five pieces in each hill throughout the whole. I did not weigh nor measure the produce, but found that the middle pieces produced much the largest crop. The produce of the other two rows were about equal; by which it appears that to reject both ends and plant the middles only, will produce much the best crop.

Ryegate, Vt. Sept. 2, 1822.

From the National Intelligencer
To Medical Gentlemen.

I have been lately amusing myself with a work published by Mr. J. L. Chabert, at New Orleans, entitled "Medical reflections on the malady vulgarly called Yellow Fever;" to which he gives the new denomination of *Spasmodico Epyriene*, or spasmodic burning fever. It is full of information respecting the symptoms of this terrible disorder, and of acute remarks on the suggestions of all prior observers. Mr. Chabert states, that by numerous dissections, he has found that the liver is not affected. The bleeding of the nose and inflammations of the throat, &c. are the first diagnostics, and after that a delusive ease succeeds, and then the black vomit.

Query.—Whether animalculæ inhaled do not first cause the spasms by inflammation, and whether mortification does not ensue? Persons not acclimated are the greatest sufferers. I have seen Europeans, arriving in Asia, when stung by musquitoes, suffer inflammation in an extraordinary manner. May not the same effect be produced by inhaling insects, imperceptible to the naked eye, by the nose and throat? That putrid matter will produce insects, has been proved by various experiments; and I have read, in your valuable widely circulated paper, that magnifying glasses have been constructed to discover insects in the lungs of those who have died of consumption.

I am not a medical practitioner, and hope to be excused for venturing to submit this hint to the scientific. A boy darting a random arrow once made it pass through a small ring which practised archers in vain attempted to shoot through. Thus, I, by a guess, may give a beneficial idea, which superior judgments may improve upon.

NOTE.—Let the doctrine of animalculæ being in the air, receive due consideration.—Iron, Magnesia and Salts, may be in the most transparent water. Air is composed, we know, of fixed portions of hydrogen, azote and oxygen, but flies, &c. may exist in it. Animation may be in the minutest objects; the microscope discloses the wonders of our Creator in the smallest degree.

ON CATCHING COLD.

As there were few men more attentive to tracing the cause of natural effects, or more ready and ingenious in accounting for them than Dr. Franklin, his opinions on any such subjects are therefore deserving our special attention. Thus, on the subject of catching cold, he alleged, that instead of a cold being contracted by the body's being exposed to some external cause which may stop the insensible perspiration, such as cold air blowing partially on some part of the body, its continuing during some time wet, &c. a feast, or some excess in eating or drinking will be generally found to have preceded. In confirmation of this opinion, he observed, that those who led temperate lives seldom caught cold, even though their constitutions and habits of body might seem little able to withstand the effects of such causes.

I was a witness of what I thought a singular instance of the truth of this opinion. Upon my mentioning it to a gentleman, who eats no animal food, and drinks no fermented liquor or spirits, he said he would give it a fair trial. He accordingly, early on the first dewy summer morning, walked among long grass till his feet and legs were perfectly wet, and continued out of doors from 6 till 8, and when he came in to breakfast could not be prevailed upon to have dry shoes and stockings till he returned to dress at noon. No cold ensued, though wet feet are reckoned among the most frequent causes of taking cold. He afterwards thanked me much for freeing him from many restraints founded, as he now experienced, on prejudice.

Dr. Franklin remarked, that those who eat no suppers, especially after plentiful dinners, were much less liable to catch cold, for they thereby avoided adding a quantity of indigested juice with what are, in some degree, in a digested state. They who make their supper their principal meal do not suffer by it, because the stomach being pretty empty, an improper mixture of juices does not enter the lacteals.

SPONTANEOUS COMBUSTION.

On Friday afternoon the barn of Mr. George Shute, of Malden, containing ten tons of hay, all his farming utensils, and a chaise, was consumed by fire. Mr. S. with another man, was at work in a field near the barn, when the fire burst out; but nothing could be done to save it. This is another instance of spontaneous combustion, proceeding probably from the too green, or damp state of the hay, as it is almost certain there had been no fire conveyed to the barn, by any direct or accidental means.

From Niles' Register.

FLAX

Another machine has been invented by Samuel Davidson, of Romulus, N. Y. for dressing flax. Its whole cost, including the patent right, is only forty dollars. It has been tried by many of the most respectable farmers. They estimate the saving in the labor at three fourths, and the saving in flax at one fifth, compared with the common mode; while it leaves the texture of the thread unbroken. By the use of this machine the process of *rotting* may be dispensed with, as it will answer for dressing the flax either with or without rotting.

This improvement promises to be extensively useful—its price is small that every neighborhood may easily have a machine. Flax is an article of easy cultivation and great product, if the process of rotting and usual way of cleaning it can be dispensed with, and must become an important staple to the people of the interior for home use, and transport to the seaboard, &c. A pound of flax may be carried any given distance as readily as a pound of corn, pork, &c. The cost of transportation will be the same; but the amount of that cost as to the relative value of the article, will be essentially different. The seed too, if crushed and made into oil, will always find a ready market, and better pay charges for carriage than any sort of provisions that our farmers can raise in the interior. Oil mills may be erected at a small expense, and would yield large profits to their owners, if the supply of seed were abundant, in any part of our country west of the mountains.

We feel both publicly and personally interested in the cultivation of flax and the use of flaxen goods—publicly, because it will add much to the national prosperity; privately, because we cannot have good *paper* without flaxen rags to make it of.

From the Montreal Gazette of August 31.

AGRICULTURAL REPORT FOR AUGUST.

The cutting of grain became common from the 10th to the 15th of the month; about the 19th the weather was very unfavorable for rural or harvest affairs; very heavy rains with warm growing weather, which lasted some time, have done considerable damage to Grain lying on the ground (the common way in this country) as it has rendered the straw black, and caused the crop to spring or sprout. If the Canadian farmers would bind and shock their crops as they cut them, like old country farmers, it would be a great saving of fodder to them in rainy seasons; indeed we have had more wet weather this summer than in the three preceding.

Towards the latter end of the month, we had excellent dry days, with a strong or good breeze which has enabled the farmers to house a great part of their crops, and a few fine days will finish the bulk of the harvest.

Grass-seeds have generally taken well and after grass looks fine.

Of Turnips little is heard, but Mangel Wurtzel is much recommended by all who have raised it; the quantity on an acre is said to be very great, and it is not subject to be injured by the fly or grasshoppers.

Cutting Hay on natural wet meadows has been attended with much trouble, and some very extensive fields are still uncut, being overflowed with water.

Stock of all kinds is in excellent condition; milch cows are very scarce, bees have thrived well this summer, and it is a matter of surprise and regret that they are not more generally kept both for the profit they give, and the good example they set before us. Laborers are in abundance, good reapers have been commonly paid from 1s. 6d. to 1s. 10d. per day.

A pair of the beautiful and gigantic nondescript Elks, known by the Indians of the Upper Missouri (where they have been lately discovered) by the name of Wapetti, arrived here on Monday se'n-night on their way to London. These noble animals are the size of the horse, with immense spreading horns; their form the most perfect model of strength and beauty, combining the muscular strength of the race horse, with the lightness and agility of the greyhound; are capable, with ease, of drawing a carriage or carrying a person more than twenty miles an hour. They are perfectly domesticated, and of the most amiable and gentle disposition. Their flesh is esteemed the finest of venison; and as the female is on the point of producing young, no doubt is entertained of adding this most noble and interesting quadruped to our stock of domestic animals. They will be exhibited for a few days at Stokes' Rooms, next door to the Athenaeum, in Church street.—*London paper.*

NEW ENGLAND FARMER.

BOSTON.—SATURDAY, SEPT. 14, 1822.

TO READERS, CORRESPONDENTS, WELL-WISHERS, ADVISERS, &c. &c.

We have been eminently favored, since the commencement of the New England Farmer, with a multitude of counsellors, who have from time to time volunteered opinions respecting the course it was best for us to pursue in conducting the publication. But, it unfortunately so happens that but rarely any two of our monitors agree in their precepts; and as we cannot, at the same moment, move in a great variety of opposite directions, we shall take in good part, what was doubtless well meant, but hope to be excused, if we do not exactly conform to rules and regulations, which do not always accord with each other, any better than with our own views of the subjects to which they relate. Still we are happy to receive counsel, though for the reasons above mentioned we cannot always comply with it. Besides, our advisers, surely, do not wish to be our controllers; and if they will kindly continue to *shed light on our paths*, we will spare them the trouble of *directing our feet*.

The gentleman who advises us to write a "System of Georgicks after the manner of Virgil," borrowing hints from the "elegant works of Darwin," &c. is respectfully informed that if we had talents, we have not time to spare for such a purpose. A number of years (certainly not less than nine according to Horace) would be requisite to complete such a work; and by the time it was finished, a considerable part would probably become obsolete by improvements which are every day unfolding. We believe moreover, that the principles of science, and the details of art, are, generally speaking, better given in plain prose than in the "linked sweetness" of Dr. Darwin's most mellifluous modulations. For instance, Dr. Darwin's poetical description of the Steam Engine would hardly serve as a specification to enable a workman to build a machine of the kind; and should even a greater than Darwin undertake to give versified accounts of many of the

most useful modern improvements in agriculture, ninety nine in a hundred of the cultivators of the soil

"Would read, and read, then raise their eyes in doubt,
"And gravely ask—*Pray what's all this about?*"

Georgicks, and poetical descriptions of rural occupations and amusements, are, however, very pretty articles, and we should be glad of an assortment for the benefit of *some* of our readers, who like our correspondent alluded to, have taste enough to read and relish such things. Our attention must, however, for the present, be more directed to the wants of the many than the taste of a few.

A gentleman from Vermont writes to us as follows:—"We have tried your receipt for using elder juice [see page 3.] in a large dairy, on two or three cheeses that were much cracked, and from which it was difficult to keep the flies that produce skippers. The experiment answers perfectly—the flies do not even approach that part of the pantry. No doubt it will answer other valuable purposes."

The gentleman who has given us an account of his experiments with Seed Potatoes will accept our thanks, and is requested to continue his favors.

The articles on "Preparing Flax," in the preceding page, merit much attention from all who feel an interest in developing the natural resources of our country. We hope new lights will be elicited from actual experiments, whose details and results we should be happy to publish.

ON SAVING AND MAKING THE MOST OF MANURE.

No soil will always prove productive without manure. Though naturally fertile as the garden of Eden, if it is always giving and never receiving, it will at length become as barren as a desert. Manure then, in farming, is all in all. It is that without which there will soon be

"Nothing in the house—nor in the barn neither."

Particular spots, like Egypt, and other alluvial or intervale lands, which are annually overflowed, derive manure from the bountiful hand of nature, and cannot be exhausted by bad husbandry. Some soils likewise are not easily exhausted, and are easily recruited, in consequence of being so organized as to attract from air and water the principles of fertility.

But if the soil is *naturally barren* it may be *made fertile*. If land in its natural state be good for nothing but to hold the globe together (as some have quaintly expressed it) it may be made abundantly fruitful by being mixed with certain earths, composts, dung, &c. together with a judicious rotation of crops. "In the Pays de Waes, in Flanders, sand is cultivated to great perfection. The soil of that district, which was originally a barren white sand, has been converted into a most fertile loam."* This was effected by suitable applications of clay, marl, vegetable and animal manure, deep ploughing, turning in green crops, &c. The most barren pitch-pine or shrub-oak plains in New England may be rendered fertile by similar processes. And in many instances it is better thus to convert a piece of poor land, which is favorably situated as regards government, the state of society, the market, &c. into an excellent farm, than to seek a farm in the wilderness, where there is neither government, society, nor any of the comforts and enjoyments of civilized life; and which, with all these disadvantages, cannot be rendered productive without a great deal of labor and expense.

The principal agent in converting a barren to a fruitful soil must be manure: either fossil manure,

* Code of Agriculture.

(such as the earths, salts and alkalis) or animal and vegetable manure, composed of decayed and decaying animal and vegetable substances. Our observations, at present, will be confined to the latter kind.

A controversy has existed for some years, relative to the degree of fermentation which manure ought to undergo, before it is applied to the soil. Some agriculturists are advocates for long, fresh, or unfermented manure, and others contend that it should never be spread on the field till the fibrous texture of the vegetable matter is entirely broken down, and it becomes perfectly cold, and so soft that it may be easily cut by a spade.

Sir Humphrey Davy, whose authority, on subjects of this kind, should not lightly be called in question, observes, "If the pure dung of cattle is to be used as manure there seems no reason why it should be made to ferment except in the soil; or if suffered to ferment it should be only in a very slight degree. The grass in the neighborhood of recently voided dung is always coarse and dark green; some persons have attributed this to a noxious quality in unfermented dung; but it seems to be rather the result of an excess of food furnished to the plants.

"During the violent fermentation, which is necessary for reducing farm-yard manure to the state in which it is called *short muck*, not only a large quantity of fluid, but likewise of gaseous matter is lost; so much so, that the dung is reduced one half or two thirds in weight; and the principal elastic matter disengaged, in carbonic acid with some ammonia; and both of these, if retained by the moisture in the soil, are capable of becoming useful nourishment of plants.

"It is usual to carry straw that can be employed for no other purpose to the dunghill to ferment and decompose; but it is worth an experiment whether it may not be more economically applied, when chopped small by a proper machine, and kept dry till it is ploughed in for the use of a crop. In this case, though it would decompose much more slowly, and produce less effect at first, yet its influence would be more lasting.

The Farmer's Magazine, a British periodical work of celebrity, opposes this theory of Sir Humphrey Davy. The conductor says that he "has known dung and litter, which had been turned down fresh in the furrow appear the next spring without any visible change. Of course it must have lain dormant, without contributing to the growth of the plants. Dry wheat straw was regularly laid in the hollow of drills, and potatoes planted above the straw. Both were then covered with earth; but very few of the potatoes ever came above ground, and those only towards the end of autumn. When the field was afterwards ploughed, the straw seemed to have undergone no change; nor did it convey any sensible benefit to future crops. Had the same straw been previously subjected to only a moderate fermentation in the dung-yard, there can be no doubt but its effects would have been very different."

The Hon. Richard Peters, of Penn. is likewise opposed to the use of unfermented manures. He observes in a letter to the Hon. Mr. Quincy, that "straw muck cannot be regularly spread. The animal matter is not mixed with the straw, but lies in masses *per se* [by itself.] This over ferments, and throws up your crops in bunches or spots, over luxuriantly; and it lays, smuts, or mildews. The earth prevents fermentation in the straw; and this dry rots, and becomes a *caput mortuum*, [dead useless mass.] I have experienced this effect over and over again. I think reasonably fermented dung goes further. All the straw and additional matter is impregnated, and being decomposed, spreads with the animal objections more equally, and to

infinitely better advantage, testing your crops in more points, and operating efficiently on the whole."

Mr. Robert Smith, President of the Maryland Agricultural Society, appears to entertain a different opinion on this subject. This gentleman in an Address to the Maryland Agricultural Society observes, "with respect to stable dung I shall, for the present, content myself by barely suggesting that my experience strongly inclines me to the opinion that, however long, it ought to be ploughed into the ground, without any previous stirring, and as soon as practicable after it shall have been taken from the farm yard."

* See *Mass. Agricultural Repository*, vol. iv, p. 323.

† See *American Farmer*, vol. iv, p. 32.

(TO BE CONTINUED.)

The Essex Agricultural Exhibition will be at Toppsfield, the 2d of October. Over 600 dollars will be awarded in premiums. Address by the Rev. Dr. Eaton of Boxford. Dinner tickets fixed at 50 cents.—Further particulars respecting this Exhibition postponed for want of room to our next.

The orchard of Mr. Stephen Osborn, of Danvers, has produced an apple this season, weighing *nineteen and a half ounces*!

More magnificent yet!—We yesterday (says the Salem Gazette of Tuesday) received an apple which grew on a tree in Col. Pickman's orchard, South fields, under the care of that industrious and persevering husbandman, Mr. Erastus Ware, which weighed *twenty ounces*, large.

Mr. B. V. Clench, of New York, has raised a *cucumber* this year, measuring 23 inches in length, 12 in circumference, and weighing 5 lbs. 12 oz.

In a letter from James Whiton, Esq. of Lee, to the Editor of the Berkshire Star, he says, "I have raised the present season, on one acre of land belonging to my farm, *eighty-five bushels of oats*."

Munificent.—The honorable Stephen Van Rensselaer has engaged Prof. A. Eaton, of Troy, to take a Geological and Agricultural Survey of the Great Canal route from Albany to Buffalo, a distance of 35.0 miles. The survey is to include the breadth of ten miles.

A most horrid transaction took place at the jail in this city on Friday night, September 6, about 12 o'clock. It appears that Howard Trask, Francis Durgin and John Newman were all confined in one room. At about midnight, Trask got up and went to Newman's bed, where he was asleep, and without giving him the least notice of his intention, with a sharp instrument of some kind he cut open his stomach. Durgin who was in another part of the room awoke, and coming to Newman's assistance was met by Trask, who stabbed him in the breast in several places, and he would probably have inhumanly butchered them both had not their cries brought the watchmen to their assistance. They are both considered dangerously wounded. Trask is the person who was concerned with Green at the State Prison riot in October last, and was acquitted on the ground of insanity—Newman and Durgin are confined for theft. Trask refused to answer any questions put to him respecting the affair; nor hath the instrument used by him as yet been discovered.—*Evening Gazette*.

Sickness.—Within the last three weeks, nine persons have died in Guildhall, Vt. and eleven in Northumberland, N. H. of Dysentery. The extraordinary mortality is among children from six months to twelve years old. And although the disease is called the dysentery, yet it puts on a different appearance from the common and ordinary disorder known by that name. The public may expect hereafter a more particular account of the progress of this disease, and the treatment of it, by some of the Physicians attending on it.

Octavius Pickering, Esq. is appointed by the Governor and Council, Reporter of the Decisions of the Supreme Judicial Court of this Commonwealth, in the place of Mr. Tyng, who has resigned the office.

YELLOW FEVER AT NEW YORK.

On Sunday last 4, Monday 4, Tuesday 6, Wednesday 11 cases. There has been about one hundred deaths since the commencement of the fever.

The Board of Health announced on Tuesday the death by yellow fever of Mr. George Gilbert Warren, of New York, at one of the most frequented public houses in town. He arrived in town on the 23d ult. and was taken ill on the 3d inst. and died on the morning of the 9th. It is by no means remarkable that a single individual, of the great number of persons who have come to town directly from the diseased district in New York, should have sickened here of the fever, nor does it afford any ground for alarm to those who have not been in that district. It is a very satisfactory proof of the favorable change of the public opinions in relation to this disease, that this gentleman was suffered to remain where he could have the most comfortable accommodations, and the best attendance, and that none of the numerous lodgers in the very respectable house where he sickened, have in consequence fled from their quarters.—*Daily Advertiser*.

A second Lambert!—There is a gentleman living in the town of Centerharbour, in this State, Mr. Caleb Towle, a wealthy and respectable farmer, whose height is 5 feet 10 inches, girth 7 feet, and weight 515 pounds. He is obliged to use a second chair for the more bulky part of his frame.—*Portsmouth Journal*.

Dartmouth College.—On Thursday, the 23d ult. the prize declamations took place at this Seminary. The prizes were awarded to George K. Pomroy, of Boston, Michael Lovell, George Boardman, and John Chamberlain, members of the College.

At 11 o'clock, the exercises of the Phi Beta Kappa commenced; when an elegant and classical oration was delivered by Professor Oliver, late of Salem. It is said to have been written in a style of neat simplicity and perspicuity seldom surpassed.—The Society elected the Hon. Daniel Webster, of Boston, for their President during the ensuing year.—*ibid*.

AGRICULTURAL NOTICE.

THE Trusters of the Plymouth County Agricultural Society, having agreed to offer in premiums, the sum granted by the government, for that purpose, and also the income of the funds belonging to said society, do hereby give notice, that there will be a CATTLE SHOW, and EXHIBITION OF MANUFACTURES, &c. &c. at South Bridgewater, on **TUESDAY, the Eighth day of October next**, at 9 o'clock, A. M.—and that an Address is expected on the occasion, by Hector Orr, Esq.

Candidates for premiums are requested to communicate their intentions to Bartholomew Brown, or Daniel Mitchell, Esqrs. previous to the first day of said Oct'r.

DANIEL HOWARD, President.

West Bridgewater, Sept. 1822.

SPEED THE PLOUGH.

THE subscriber (late President of the Berkshire Agricultural Society) convinced of the importance of disseminating improved Agricultural Implements, and that it can only be effected in an efficient manner, thro' the medium of persons who are *practically* conversant with, and able to judge of their true merits from experience, proposes to open a REPOSITORY for the sale, on commission, of all kinds of Agricultural Implements and Machinery.—*Likewise*, for Prime Seeds, and approved Agricultural Books.

It being the object of the subscriber to bring into use such articles only as possess real merit, it is proper to remark, that he will offer none for sale but such as he may be really acquainted with, or which he shall have previously tested by experience.

Letters, *post paid*, will be duly attended to, and all favors gratefully acknowledged.

THOMAS MELVILL, Jr.

Pittsfield, (Berkshire Co.) Sept. 10, 1822.

SUBSCRIBERS to the NEW ENGLAND FARMER who wish to be considered as paying *in advance* for the first Vol. must forward us \$2.50 on or before the first day of October next. All who neglect paying at that time will be charged \$3. We give this reasonable notice that none may complain, as this rule will be strictly adhered to. ~~Old~~ New subscribers can be furnished with complete files from the commencement. Sept. 7.

(*The following is but little inferior to Thomson's famous "Palmon and Lavinia."*)

THE MILK MAID AND HER LOVER.

Who hath not heard
Of Patty, the fair milk maid? Beautiful
As an Arcadian nymph; upon her brow
Sat virgin modesty, while in her eyes
Young sensibility began to play
With innocence. Her waving locks fell down
On either side her face in careless curls,
Shading the tender blushes in her cheek.
Her breath was sweeter than the morning gale
Stol'n from the rose or violet's dewy leaves.
Her ivory teeth appear'd in even rows,
Through lips of living coral. When she spoke
Her features wore intelligence; her words
Were soft, with such a smile accompanied,
As lighted in her face resistless charms.
Her polish'd neck rose rounding from her breast
With pleasing elegance:
Her shape was moulded by the hand of ease,
Exact proportion harmoniz'd her frame;
While grace, following her steps, with secret art
Stole into all her motions. There she walk'd
In sweet simplicity; a snow white pail
Hung on her arm, the symbol of her skill
In that fair province of the rural state
The dairy; source of more delicious bowls
Than Bacchus from his choicest vintage boasts.

How great the power of beauty! the rude swains
Grew civil at her sight; and gaping crowds,
Wrapt in astonishment, with transport gaze,
Whispering her praises in each other's ear.
As when a gentle breeze, borne through the grove
With quick vibration shakes the trembling leaves,
And hushing murmurs run from tree to tree;
So ran a spreading whisper through the crowd.
Young Thyrus, hearing, turn'd aside his head,
And soon the pleasing wonder caught his eye.
Full in the prime of youth, the joyful heir
Of numerous acres, a large freehold farm,
Thyrus as yet from beauty felt no pain,
Had seen no virgin he could wish to make
His wedded partner. Now his beating heart
Felt new emotion; now his fixed eye,
With fervent rapture dwelling on her charms,
Drinks in delicious draughts of new born love.
No rest the night, no peace the following day
Brought to his struggling heart; her beauteous form,
Her fair perfections, playing on his mind,
With pleasing anguish tortur'd him. In vain
He strives to tear her image from his breast;
Each little grace, each dear bewitching look,
Return triumphant, breaking his resolves,
And binding all his soul a slave to love.

Ah! little did he know, alas! the while,
Poor Patty's tender heart in mutual pain,
Long, long for him had heav'd the secret sigh.
For him she drest, for him the pleasing arts
She studied, and for him she wish'd to live,
But her low fortunes, nursing sad despair,
Check'd her young hopes, nor durst her modest eyes
Indulge the smallest glances of her flame,
Least curious malice, like a watchful spy,
Should catch the secret, and with taunts reveal.
Judge then the sweet surprise, when she at length
Beheld him all irrevocably approach,
And gently taking her fair trembling hand
Breathe these soft words into her listening ear.
"O Patty! dearest maid, whose beauteous form
"Dwells in my breast, and charms my soul to love,
"Accept my vows; accept a faithful heart,
"Which from this hour devotes itself to thee;

.. Wealth has no relish, life can give no joy,

.. "If you forbid my hope to call you mine."

Ah! who the sudden tumult can describe
Of struggling passions rising in her breast.
Hope, fear, confusion, modesty and love
Oppress her laboring soul;—she strove to speak,
But the faint accents died upon her tongue;
Her fears prevented utterance;—at length
"Can Thyrus mock my poverty? Can he
"Be so unkind? O no! yet I, alas,
"Too humble e'en to hope?"—No more she said;
But gently, as if half unwilling, stole
Her hand from his; and with sweet modesty,
Casting a look of diffidence and fear,
To hide her blushes, silently withdrew.
But Thyrus read with rapture in her eyes
The language of her soul. He follow'd, woo'd
And won her for his wife. His loving herds
Soon call her mistress; soon their milky streams
Coagulated, rise in circling piles
Of harden'd curd; and all the dairies round
To her sweet butter yield superior praise.

INDUSTRY AND FRUGALITY.

Extracts from Dr. Franklin's writings, and which cannot be too often read, nor too long remembered.

If we are industrious, we shall never starve; for at the working man's house, hunger looks in, but dares not enter. Nor will the bailiff or the constable enter, for "Industry pays debts, while despair increaseth them." What though you have found no treasure, nor has any rich relation left you a legacy, "diligence is the mother of good luck, and God gives all things to industry. Then plough deep while sluggards sleep, and you shall have corn to sell and to keep. The diligent spinner has good clothes, and now I have a sheep and a cow, every body bids me good morrow."

Remember what poor Richard says, "Buy what thou hast no need of and ere long thou shalt sell thy necessities." And again, "At a great pennyworth pause a while;" he means, perhaps, that the cheapness is apparent only, and not real; or the bargain, by straitening thee in thy business, may do thee more harm than good.

"If you would know the value of money, go and try to borrow some: for he that goes a borrowing goes a sorrowing," as poor Richard says; and indeed so does he that lends to such people, when he goes to get it again.

"Creditors have better memories than debtors—creditors are a superstitious sect, great observers of set days and times."

Remember that time is money. He that can earn ten shillings a day by his labor, and goes abroad or sets idle one half of that day, though he spends but sixpence during his diversion or idleness, ought not to reckon that the only expense—he has really spent, or thrown away five shillings besides.

Remember this saying, "The good paymaster is lord of another man's purse." He that is known to pay punctually and exactly at the time he promises, may at any time, and on any occasion, raise all the money his friends can spare.

The most trifling actions that affect a man's credit are to be regarded. The sound of your hammer at five in the morning, or at nine at night, heard by a creditor, makes him easy six months longer; but if he sees you at a billiard table, or hears your voice at a tavern, when you should be at work, he sends for his

money the next day—demands it before he can receive it in a lump.

Beware of thinking all your own that you possess, and of living accordingly. It is a mistake that many people who have credit fall into. To prevent this, keep an exact account, for some time, both of your expenses and your income. If you take the pains at first to mention particulars, it will have this good effect—you will discover how wonderfully small trifling expenses amount up to large sums, and will discern what might have been and may for the future be saved, without occasioning any great inconvenience.

In short the way to wealth, if you desire it, is as plain as the way to market. It depends chiefly on two words, *industry and frugality.*

LAW OF PATENTS.

CHARLES EWER, No. 51, Cornhill, has just published, price \$3.50, bound,

AN ESSAY ON THE LAW OF PATENTS FOR NEW INVENTIONS. BY THOMAS GREEN FESSENDEN, Counsellor at Law.

"As the West Indies had never been discovered, without the discovery of the Mariner's Needle; so it cannot seem strange, if Science be no farther developed, if the Art itself of Invention and Discovery be passed over."—BACON.

The second edition, with large additions, corrected and improved by the author.

RECOMMENDATIONS.

EXTRACTS FROM LETTERS TO THE AUTHOR.

Salem, Sept. 4, 1821.

SIR—I have examined your MS. on the Law of Patents with as much care as my engagements would permit, and I have no hesitation in expressing my opinion, that the work will be highly useful to all persons who are engaged in obtaining patents, or in vindicating them in Courts of Justice. The manuscript contains a collection of all the cases, on the subject of Patents, within my knowledge; and the principles contained in them are detailed with accuracy and fullness in the Summary, at the conclusion. I know of no work so comprehensive as yours on this subject; and it may be relied on as a safe guide. I hope you will receive encouragement sufficient to justify the publication, which I should think would be profitable as well as extensively useful.

JOSEPH STORY.

Thomas G. Fessenden, Esq.

Boston, September 25, 1821.

SIR—We have looked over the manuscript of the second edition of your publication on the Law of Patents. This edition is a great improvement on the first, and we think it will be a valuable and useful book to the profession, as it contains the statutes, and states we believe accurately, all, or nearly all the decisions, which have been made on a branch of the law, daily growing more interesting and important.

WM. PRESCOTT,

Thomas G. Fessenden, Esq. D. WEBSTER.

Boston, September 27, 1821.

SIR—The new edition of your Essay on Patent-Law, which I have taken some time to examine, is a very improved work. More ample materials, furnished to your hands, by decisions, subsequent to your former edition, have enabled you to present to the public, and the bar a more minute analysis, as well as a more comprehensive view of this branch of law than has yet appeared in England or in this country. Your method of arranging all the decisions, in the order of an analytical digest of the several requirements and provisions of our statutes for granting patents, puts the lawyer at once in possession of the judicial construction of the statutes; while your synthetic summary, far more extended and comprehensive than in the former edition, places within reach of the mechanic a sure means of judging whether his invention is a fit subject for a Patent; what is required of him by the statute in order to obtain his Patent; and what provisions are enacted for securing to himself and heirs his meritorious privilege. I cannot conclude without wishing you the success your labors surely deserve.

No. 3.

CONSIDERATIONS

ON THE NECESSITY OF ESTABLISHING AN AGRICULTURAL COLLEGE.

and having more of the children of wealthy citizens educated for the

PROFESSION OF FARMING.

(Continued from p. 50.)

It is a mistaken idea that nothing can be made by farming. Universal fact proves the contrary. The chief part of our immense population lives by it, and lives too in a comfortable, and very many of it in a luxurious state. It is a fact, not now noticed for the information of our countrymen, who all know it, but as a contrast to what prevails on the other side of the Atlantic, where probably it will be considered incredible, that our farmers' tables are ordinarily furnished, three times a day throughout the year, with as much meat, besides a superabundance of vegetables, as their families and their laborers can use, and that two, out of the three meals a day have commonly coffee or tea, with sugar and cream or milk for their accompaniments. It is fervently to be wished, that a more economical mode of living were adopted—but so is the fact. Is this making nothing by farming? Which of the other pursuits of life furnish more of the means of comfortable living? Do we not often see it the source of riches and abundance, while many in other professions find it difficult to subsist? It is the only one that is independent. Indebted to his industry, and the ordinary goodness of providence alone, the farmer can live should all others be annihilated. His bosom is free from the anxieties which agitate others, who have not the same certainty of enjoying a competency, who know not whether there will be sufficient openings for their industry, whether their labors will be duly appreciated, or whether the chances on which success depends will eventuate for or against them.

Hope, which only can illumine the gloom that envelops humanity, and assuage its sufferings, holds her lamp, burning with a bright equitable flame, before the cultivator of the earth; while to others, it appears and disappears and appears again, like the wandering fire of an ignis fatuus, or flutters like the faint light of a glimmering taper, or like a meteor blazes intensely for a while, then vanishes forever.

Travel through our country, especially the western parts of this state; look at the groups of rosy, well clad children, that swarm from their dwellings, and cluster about the school houses; observe the neatness and elegance of the farm houses as you pass them; examine their appendages of out-houses, gardens, orchards and fields, stocked with cattle, or enriched with crops ripening for the harvest, and estimate their value; go into the churches, raised in all their magnificence, from the surplusages of farms, and behold the brilliance of appearances there, where not a single object, with the marks of poverty on it, is found to disfigure the scene; enter some of the stately abodes which will meet you with frequent occurrence; see the plenty, independence, comfort and happiness predominant in them, which

the lords of palaces might envy, but which they never can know; ask if these are the fruits of a fortunate or prosperous ancestry; you will be told, no! they have all been extracted from the soil by a judicious and industrious application of their present owners to the business of agriculture. After this say—is there nothing to be made by farming?

Little do many think what they make by it. Let them only calculate the amount of every article that enters into the consumption of their families, according to the prices which the inhabitants of cities pay, and they may obtain some idea of the produce of their farms. Some of them, and those not of the wealthiest, will no doubt, at the end of such a calculation, be astonished to find that, with all their economy and avoidance of extravagance, and notwithstanding their previous very different belief, they live at the rate of two or three thousand dollars a year: a fact easy to be ascertained by keeping regular accounts; and yet many such have accumulated no ordinary fortunes to bequeath to their families.

Englishmen, in their characteristic vainglorious manner, exult in the happy condition of their farmers; and what is that condition? They cultivate a soil not superior, but perhaps on an average rather inferior to ours. The price of their land, compared to that of ours, is exorbitant, and rents of necessity are equally exorbitant. They possess no incommunicable *arcana* for managing their business; on the contrary, the American genius is well calculated to outstrip them, and will most undoubtedly do so, under the influence of that spirit which has become so active of late, in all the niceties of husbandry. One third, probably one half, if not more, of the fruits of their labor is taken from them, without remuneration—by tithes to support an ecclesiastical nobility with its numberless dependents,—by taxes to pay the interest of a national debt, of incomprehensible magnitude, incurred for carrying on a savage warfare against the human race, almost without intermission, for centuries past, and for the support of an aristocracy, of which the thousands that compose it, each must be supported in a style of magnificence which the first magistrate of this nation cannot afford—by the poor-rates exacted from them to keep a great portion of their immense population from actual starvation—and by what is drawn from them in private charities by that enormous mass of *pauperism*, utterly inconceivable to Americans, which overwhelms the nation, and not being adequately provided for by the public, continually assails their humanity with irresistible importunities. It is from this compulsive display of British humanity, that Britons, proud Britons, have obtained a character at home so perfectly the reverse of what their public acts have indelibly stamped on them abroad.

If then the English farmer, after having so much of the fruits of his labor taken from him, can, as represented by his own countrymen, live in an enviable style, what must we say of the American, whose contributions for the support of government, and all needful charitable pur-

poses, are comparatively but as a drop in the bucket, or the small dust in the balance!

O fortunatos, si sua norint bona, colonos!

But with all these superior advantages of the American farmer, it is nevertheless true, and it is no less true in regard to every other profession, that he who has not been in the way of becoming thoroughly acquainted with actual farming, will make nothing by it, or rather will sink his fortune in the attempt. A rich young man, sent into the country to prosecute farming, without an education for it, will, most assuredly, be cozened and swindled out of property, till all be lost; on the contrary, a competent knowledge of his business, to be acquired only by a regular education for it, would make it to him, if not a mine of wealth, at least the means of an affluent living.

The inference from all these facts and observations then is, that there is and must remain an insurmountable barrier to prevent the sons of men of other professions, and especially of the rich, from becoming farmers, unless there be some institution in which they can receive an education for that profession in a manner different from what is now possible:—That it would be incalculably for the benefit of our country if the surplus candidates for other professions, could be diverted to this, the most useful of all:—And therefore, that an institution specially intended for this purpose is of the greatest importance—that it is demanded by every consideration of the wisest policy, and that the resources of government cannot be better employed for any other object for which governments are formed.

It may be called an agricultural *school, academy or college*, no matter which; but if any importance is to be attached to names, I would give it the most respectable, and call it THE AGRICULTURAL COLLEGE OF THE STATE OF NEW-YORK.

Its primary object should be to teach *the theory and practice of agriculture*, with such branches of other sciences as may be serviceable to them: its secondary, *to make improvements*.

This state has been liberal, almost to excess, in the endowment of other colleges. For the purchase of but a little, almost useless, and now nearly neglected appendage to the college of physicians and surgeons—*Hosack's botanical garden*—a sum has been given which alone would place the all-important institution now advocated, on a respectable footing. After this, an endowment of such an institution as this cannot be consistently refused.

If then an agricultural college is of the importance thus clearly evinced—if the best interests of the community so eminently depend on it—if numbers of youth in the wealthiest families must without it, be abandoned to dissipation, and finally to ruin—if the perplexities, despair, and melancholy prospects of their parents, in regard to the destinies of their children, can be removed only by it, and if capital to an immense amount, otherwise devoted to annihilation in the sinks of prodigality and vice, can by it be drawn into the most productive employment, then surely must the agricultural college share the patronage of government, at

least equally with others; nay, it must become the DARLING FAVORITE.

There is another aspect of this institution not unworthy of serious meditation. Men filling the professions exclusively called the *literary*, have too great a preponderance in our political machinery. This necessarily results from their qualifications, derived from a superior education, giving them a superior power to accomplish their purposes, and which directed by an *esprit de corps*, as it unavoidably must be, cannot be expected always to harmonize with the general interests of the community. It has been observed, and not altogether without reason, that in some places, the clergy have had too much of a controlling influence over the politics of a state. Of such an aristocracy however, this state, we are proud to say, has had no reason to complain, and has nothing to fear. But the greatest evil of this kind, in our country in general, is most to be apprehended from the profession of law. Every one on reflection, must perceive the extent of the present existence of this evil, and may conjecture to what, without a remedy, it will ultimately grow.

The profession of law is considered, more than any other, as directly in the line of promotion to the highest offices, and therefore, like lottery gamblers, among at the highest prize, most ambitious families destine some of their branches for it; but the profession becoming thereby overstocked, numbers are necessitated to intrigue for measures specially favorable to their individual interests, and which may raise them to more fortunate stations. And thus are their superior acquirements, for want of a sufficient counterpoise, successfully employed with other views than the promotion of the public good. When markets are glutted with any commodities, the ingenuity of traders will be stretched to the utmost for discovering ways by which they may dispose of them, and necessity too often urges them to the adoption of unjustifiable means to effect their purpose. Not a few of the lawyers of the inferior grades, it is believed, are in similar circumstances, and obliged to resort to a similar sinister conduct.

These animadversions on the profession of law, as at present existing in our country, are by no means intended to disparage the profession; on the contrary, it must be confessed that to it we are indebted for the greatest blessings of government, the due investigation and correct discrimination of the rights of the people, and the execution of the laws for their security and protection. An honest, well qualified lawyer, with suitable dispositions, in any community, can be one of its most extensive public benefactors. To him the oppressed may flee, with a consoling confidence, as to a guardian angel, and be sure of relief. But the evil which has been noticed, and which in its progress is considered to have an aspect sufficiently malign to justify apprehensions of its dangerous growth, arises from the superabundance of the numbers annually added to the profession, and the want of talents, elsewhere, to form a counterpoise to its preponderating weight. But we cannot pull up the tares, lest thereby we destroy the wheat also.

The most effectual, if not the only remedy for this evil then is, to introduce more men of accomplished education into the agricultural department, men who shall have discernment suf-

ficient to detect the tendency of sinister measures that may be artfully projected, and the masked batteries that may be raised in hostility to the public good, and be able to meet the champions of them with their own weapons, and with equal dexterity in the use of them. It is believed that nothing better can be devised, for bringing about this most desirable reformation, than the proposed agricultural college, and the dissemination of similar institutions throughout the nation: and if so, this view of it urges, with additional force, the necessity of its adoption, for giving a still higher finish to our already most wonderfully improved political fabric; the most perfect existing model of government; the wonder and the envy of the world.

In our ordinary institutions we have been the mere copyists of foreign establishments. The happy peculiarities of our country require something different; and it would be an eternal blot on the American character if we had not the genius and the boldness to tread out of the paths traced in barbarous times, and pursue a course suited to this new world, so very different from the old; especially in regard to the matter now contemplated, which so eminently involves the highest interests of our country. Let it then belong to the state of New-York, to give birth to an institution, which, if the view now taken of the subject be correct, will exceed all others in immediate and most lasting substantial utility. She will then have the praise of being the mother of *agricultural schools*, by which the cultivation of the earth, in the best possible *known* manner, will be taught, and ultimately improved to the highest possible state of perfection.

One other very important effect will be produced by such an institution. Comparisons will be made between the practice of those who are educated in it, and those who are brought up to farming in the ordinary way; and thereby an emulation will be excited that will cause exertions, which would not otherwise be made, for making continual further approximations to the maximum of improvement.

(TO BE CONTINUED.)

MASSACHUSETTS AGRICULTURAL REPOSITORY AND JOURNAL, FOR JUNE.

(Continued from p. 43.)

By a long article on the subject of cutting rings in the bark of fruit trees and other trees and plants, extracted from a foreign publication, among other facts we learn that,

"All apple trees form an abundance of additional flower buds, in consequence of ringing; but if the ring be wide, the ringed branches, especially young ones, speedily become sickly; it is therefore advisable, with them not to cut rings of greater width, than what will be closed up, at the end of the same season, or early in the following year; besides, it seems that the improvement in size and beauty, is obtained chiefly in the first year of the ringing, therefore the rings of apple trees certainly should not exceed a quarter of an inch in width, on strong branches, and they should be narrower on small and weak shoots. Fresh branches on the same tree, ought to be annually ringed, and thus a succession of produce be uninterruptedly kept up."

A Mr. Twamley found by experiment that

"the rings made in horizontally trained branches do not so readily close up as those on upright growing ones; and he found an advantage in protecting the exposed part of the wood at the ring with grafting clay." Another gentleman "made his rings a quarter of an inch wide, at the end of April and beginning of May, and in the winter covered the open rings with clay and cow dung. The fruits of all, in comparison with the produce of the unringed branches, were, exclusive of the additional quantity, either altered in size or in color, but did not keep so well, and were thought inferior in flavor, which is the natural consequence of the increase in size."

It appears that pear trees suffer less from ringing than apple trees. "In healthy and clear shoots, the bark of pear trees soon restores itself over the ring, unless it is cut very wide. The effect of ringing them is a certain production of blossom buds, so much so that even young trees may be brought into bearing by this means."

"The branches of plum and cherry trees sustain injury and become cankered by ringing; but as they are always free blowers, an increase of blossom by artificial means is not wanted to make them produce fruit." "Vines are much benefited by ringing; their blossom is produced on the shoots of the same year, in sufficient plenty; for additional blossoms, the use, therefore, of ringing, is not required, but increase of size, early ripening, and improvement of flavor in the grapes, all result from ringing." "The practice may be extensively and usefully applied to ornamental shrubs and plants, which do not readily blossom."

It is observed by Sir John Sinclair that, "In many cases, particularly in pear trees, cutting out a narrow ring of bark, from one third to one half of an inch, quite round the stem, has rendered the crop abundant, which otherwise would have failed. If the incision be covered with a rag, the hollow is filled up with new bark, in the space of a few weeks." Probably a small wire twisted round a branch, so as to form a ligature, might answer every purpose of cutting away the bark, without any danger of injuring the tree.

A writer in the *American Farmer*, vol. iii, p. 342, says that he has tried the experiment of ringing or girdling fruit trees, and is satisfied that fruit may be thereby produced, although the operation injures the trees. He therefore disapproves of it, and prefers *scoring*, that is making incisions into the bark lengthwise up the trunk, continuing, if necessary, along the principal branches. Indeed the only important use which, as we conceive, can arise from ringing fruit trees is found in its forcing young fruit trees to shew what sort of fruit they will produce, which will enable the owner to determine whether it would be advisable to graft them.

We have next an article on the Dwarf Indian Corn, taken from the Transactions of the London Horticultural Society. Some heads of this kind of corn were exhibited, which were produced from seed sent to the Society from Paris by M. Vilmorin, under the name of Mais a Poullet—"Chicken Corn." The plants do not exceed eighteen inches in height, are very hardy, not being injured by the spring frosts. The grains are of a bright yellow color, round and small, and the flour they contain appears to be peculiarly white and fine.

Some Notices of the Larch Tree (*Pinus Larix*) known by the several names of Juniper, Hackmatack and Larch—by John Lowell. Mr. Lowell says that the

"Hackmatack grows more rapidly, than the *real* Juniper, commonly called the red Cedar, and is more durable for posts, than that plant. It will grow on any soil, and rapidly in soils entirely different from those, in which it is usually found. I have them growing, in pure sand, without the smallest apparent admixture of loam, and on a barren gravel—a gravel, which will scarcely support grass. I have large trees in such soils 18 to 24 inches in circumference and thirty feet high, of thirteen years growth."

There are a number of varieties, which are described in the London Horticultural Transactions, and extracted into the article now under consideration. Among others are

"The Common Larch (i. e. the Larch of Great Britain) with red or pink flowers. In the duke of Athol's plantations on mountainous tracts at an elevation above the sea of 1500 to 1600 feet, this tree has, at eighty years of age arrived at a size to produce six loads of timber, appearing in durability and every other good quality, to be likely to answer every purpose, both by sea and land."

"*Pinus Microcarpa*, (a small fruited or coned Larch) the red Larch of North America. There are some trees of this kind fifty years old on the Athol estates, but they do not contain one third as many cubic feet of timber as *Pinus Larix* at a similar age. (That is, the *English Larch* furnishes three times the quantity of timber in fifty years which our own common Larch does.) The wood is so ponderous that it will not swim in water. Its cones are much shorter than those of the *Pinus Larix*, its branches weaker, and its leaves narrower."

Mr. Lowell thinks it would be well to import the cones of the English Larch and some other varieties from Scotland.

Mr. Lowell next gives an account of the success, which has attended his planting small patches of forest trees. In 1807, 1808, and 1809, he planted with forest trees from two to three acres of land, which was barren and unproductive, its whole value per annum not ten dollars. The trees were White Pine, Larch, Fir Balsam, and in the better parts, Oak of various sorts, Maple, Beech, Ash, Elm, Locust, Spruce, Spanish Chesnut, &c.

"The land was about half of it ploughed and kept open with potatoes for 2 years and then abandoned to the course of nature. The pines

were taken up out of the forest with great care, not more than 5 feet high. Wherever I had the cupidity and impatience to introduce a larger tree I either lost it or it became sickly. In some places I planted acorns, and as to my hard wood forest trees, transplanted from the woods, finding they looked feeble and sickly when they shot out, I instantly sawed them off at the ground or near it. This required some resolution, but I have been abundantly paid for it.

"The result of this experiment is this, that in a period from 13 to 15 years I have raised a young, beautiful and thrifty plantation comprising almost every variety of tree which we have in Massachusetts, which are now from 25 to 35 feet high, and some of which, the thickest white pines actually measure from 9 to 12 inches diameter. The loppings, and thinning out of these trees now furnish abundant supply of light fuel for summer use, and upon as accurate a calculation as I am able to make, I am convinced, that the present growth, cut down at the end of fourteen years from the planting would amply pay for the land at the price it would have brought. I do not mean to say, that this would be the case in the interior, but in the vicinity of Boston and of Salem. I am sure this experiment may be tried with perfect success. In Chelsea, Lynn, Cambridge, West Cambridge, some parts of Brooklyn, Wrentham, Danvers, and many other old towns, I see tracts of land which can produce but little, of any value, and which would in fifteen years, at the expense of ten days labour for the first four years on each acre, produce trees that would be worth the present price of the land. I am persuaded, that this is no loose calculation."

"I owe it to the cause of truth, to state, that I committed a very grave and important mistake in planting. From the desire to cover my land more rapidly, and to thicken my plantations for ornament, I planted my trees too near each other. I now suffer from this very natural cupidity. I cannot thin them out without hurting the beauty of the landscape, and the trees show how much they suffer by the yearly loss of their lower branches, which will always die if they have not air and moisture, and like other misers, I find myself unwilling to part with the treasure I have possessed.

"This however will not apply to the farmer who raises from a desire of profit. His trees should be placed at least twenty-five feet asunder in every direction; he will not fear, as I have done, the use of the axe to thin out his trees. I could now cut out light fuel for the supply of my family for two years, without injuring my plantation, but I have not courage to do it."

"I am aware that two objections will be made to this statement—First, that the scale of experiment was a small one, not exceeding two acres and an half. It is true; but the experiment was sufficiently large to test the utility of the measure. Secondly, that I disregarded expense, and put down the cost to the score of luxury. This is not true; I am sure that the whole labor did not exceed twenty days work of one man on an acre, and with respect to one acre of it not five days labor (in the whole) of one man, has ever been expended upon it.

"I planted the trees in two or three days, and left them to their fate; but I consider two conditions, indispensable to success. First, that

as to pines of all sorts, and other evergreen trees, they should be put out not more than four years old; not pruned, for they will not bear the knife well. Secondly, that as to hard wood forest trees transplanted from the woods, they should be instantly cut down to the ground or near it.

"It is only because we have no nurseries of forest trees in New England, that I speak of the barbarous practice of transplanting and instantly heading down. Young trees from a nursery would in all respects be preferable."

(TO BE CONTINUED.)

The Agricultural Society of Buck's County, Penna. have recommended to the citizens of this county, "to strictly prohibit the practice of gunning on their lands, inasmuch as it is believed that the present alarming increase of insects is principally owing to the destruction of birds." A writer likewise in the Farmer's Journal, of Windsor, Vt. remonstrates against the wanton destruction of the robin, whose young are fed on the insects which infest our cornfields.

In an article in the American Watchman, recommending the growth of *millet*, the following is given as the product of one acre sowed with half a bushel of that seed. Three tons of hay and 30 1-2 bushels of clean seed. The hay was consumed by horses who seemed to relish it as they would the best upland. The seed when manufactured into flour makes a cake more wholesome and equally palatable with that of buck wheat. The writer says if one bushel were sowed to the acre the crops would in all probability be proportionably better.

An experiment has been made in England to ascertain whether the manufacture of *spider webs* should be encouraged. It would require five thousand insects to make spider silk sufficient to form a single pair of stockings. It has been proved, by experiment, that the spider silk is so exceedingly fine that five threads are required to form one of the strength of the silk worms. A gentleman in England presented to a society, a pair of gloves and stockings, both from the spider web, possessing all the gloss and beauty of real silk.

Baltimore Morning Chronicle.

The influence of the *black* color upon heat was lately explained to the anatomical class of *Allopath* in the following manner:—

Two tea pots, one *black* and the other *white*, were placed on a table, and filled, each with boiling water, from the same kettle, which had been placed on the fire in the presence of the students. At the termination of the lecture, in the course of an hour, the water in the *black* tea pot had very considerably cooled, as was perceptible both to the finger, and by the thermometer, while the temperature in the *white* tea pot continued nearly at its original standard.

Calcutta paper.

The manufacture of woollen cloth, at Steubenville, Ohio, has been brought to such perfection, that an English gentleman lately examining some of the cloths at the factory storehouse, could not be persuaded but that the proprietors kept on hand an assortment of fine British cloths, and sold them for American.

FACTS AND OPINIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY.

ON DEEP AND FREQUENT PLOUGHING.

I entertain no doubt of the utility of deep ploughing; not at once, in our lands in general, but by an increase of two or three inches at every annual ploughing, until the earth be stirred and pulverised to the depth of ten or twelve inches. Indian corn planted in such a mass of loosened earth, would not, I am persuaded, ever suffer by ordinary droughts. Like a sponge, it would absorb a vast quantity of rain water, and become a reservoir to supply the want of that and all other plants. Nothing is more common in a dry summer, than the rolling of the leaves of corn; and that circumstance is often mentioned as an evidence of the severity of the drought. This rolling of the leaves of Indian corn, is the consequence, in part, of scant manuring, but still more of shallow ploughing. Few, perhaps, are aware of the depths to which the roots of plants will penetrate in a deeply loosened earth. A gentleman much inclined to agricultural inquiries and observations, informed me, near fifty years ago, that seeing some men digging a well, in a hollow place, planted with Indian corn, then at its full growth, he stopped to examine how far its roots had descended, and he traced them to the depth of nine feet. The soil was an accumulation of earth, which had run or been thrown into the hollow.

"The seeds of the common turnip, sown in warm weather, and on a soil sufficiently moist, I have known to vegetate in about eight and forty hours; and in only four or five days afterwards, I found the plants had sent down roots to the depth of four or five inches."

Mr. Pickering's Address to the Essex Ag. Soc.

Sir John Sinclair gives the following MAXIMS RESPECTING THE PROPER DEPTH OF PLOUGHING.

1. The depth to which land ought to be ploughed, must first be regulated by the depth of the soil. On thin soils, more especially on a rocky substratum, the ploughing must necessarily be shallow; but when the soil, whether light or strong will admit of it, the ploughing ought to be as deep as a pair of horses can accomplish; and at some seasons, it is advantageous to plough it even with four, particularly at the commencement of every fresh rotation.

2. The depth ought likewise to depend on the means of improving the soil; for when the land is poor, and the means of enriching it are scanty, the depth of ploughing ought to be in proportion to the quantity of manure which can be obtained.

3. Deep ploughing is highly advantageous upon every soil, excepting those where the substratum is an ochry sand. In fact, such sands are scarcely worthy of being cultivated, unless in situations where much alluvial compost, [marsh mud, &c.] or short town manure, can be procured.

4. It is a general rule never to plough so deep as to penetrate below the soil that was formerly manured and cultivated, excepting upon fallow, and then only, when you have plenty of lime or dung to add to, and improve the new soil.

5. Many farmers recommend, when fallowing land, to go as deep as possible with the first furrow; by which the subsequent furrows will

be more easily done, and to expose the soil to the winter's frost, and to the summer's heat; but when the land is ploughed in spring for a crop of oats, a strong soil cannot be ploughed in safety, above five or six inches.

6. Deep ploughing is advisable on moorish cold soils, as it affords a greater scope for the roots of plants to procure nourishment, admits the superabundant moisture to subside from them, and prevents the summer drought from making an injurious impression on the growing crops; for, on such land, shallow ploughing exposes vegetation to be starved or drowned in wet weather, and to be scorched or withered in dry.

7. It is unnecessary to plough deeper, when the seed is sown, than where there is a fair probability of the different kinds of plants sending their roots; and as beans, clover, and turnips, the only tap-rooted kinds usually cultivated in this country, seldom send their shoots above seven or eight inches down into the soil, and the culmiferous species not so far, it is probable, from these circumstances, that from seven to eight inches may be deep enough for all the purposes of ordinary culture. Occasionally, however, ploughing even ten inches, in the course of a rotation, during the fallow process, is advisable.

Deep ploughing is not to be recommended, 1. When lime or marl has been recently applied, as they have such a tendency to sink, from their weight, and the moisture they imbibed. 2. Where turnips have been eaten off by sheep on the land where they were grown. 3. When grass only two or three years old, more especially where it has been pastured by sheep, is broken up; because, owing to the extreme condensation of the soil, by the trampling of the sheep, a furrow, even of a moderate depth to appearance, will make the plough penetrate below the staple that had been cleared, by the culture given during the previous fallow. By this means myriads of the seeds of annual weeds are raised to the surface, where they vegetate, and materially injure the crop cultivated, besides replenishing the soil with a fresh supply of their own seeds. In all these cases from four to five inches will be found sufficient. And, 4. If land is infested with natural grasses, which generally run much on the surface, the first ploughing should not be deeper than is necessary to turn up the roots of the grasses that they may be destroyed.

ADVANTAGES OF DEEP PLOUGHING.

1. Bringing up new mould, is peculiarly favorable to clover, beans and potatoes; and, indeed, without that advantage, these crops usually diminish in quantity, quality and value.

2. Deep ploughing is likewise of great consequence to every species of plant, furnishing not only more means of nourishment to their roots, but above all, by counteracting the injurious consequences of either too wet or too dry a season. This is a most important consideration, for, if the season be wet, there is a greater depth of soil to absorb the moisture, so that the plants are not likely to have their roots immersed in water; and in a dry season it is still more useful, for in the lower parts of the cultivated soil, there is a reservoir of moisture, which is brought up to the roots of the plants, by the evaporation which the heat of the sun occasions.

3. By deep ploughing also, the ground may be more effectually cleared of root weeds of every description; in particular, it is the best mode of eradicating thistles.

4. By deep ploughing, animal and vegetable manures, which have such a tendency to rise to the surface, are properly covered. This cannot be done by shallow ploughing, in consequence of which much of the value of such manures is lost.

5. By deep ploughing a heavier crop is raised than can be got from a shallow furrow. An intelligent farmer, indeed, after pointing out that deep ploughing increases the staple of the soil, keeps the roots of the corn from being injured by wetness, and also enables the crop longer to resist drought, adds, "*I have ever found deep ploughing attended with good crops, when ridges, shallow ploughed, in the same field, were but indifferent;*" which seems a decisive proof in favor of deep ploughing.

The celebrated Arthur Young gives the following rules relative to Ploughing.

1. An additional depth should first be gained in autumn, that successive change of seasons may take effect in atmospheric influences, before any seed is ventured in the raw stratum first brought up.

2. The quality of that stratum should be examined; it is sometimes sterile by reason of an acid discoverable by boiling in water, and putting that water to the test of blue infusions.

3. Animal and vegetable manures cannot be buried; at whatever depth they are deposited, their constant tendency is to rise to the atmosphere.

4. Fossil manures are extremely liable to be buried, having a constant tendency downwards. Chalk, marl, and clay, are sufficiently soluble, or so miscible with water as to sink in a regular mass, and are sometimes found much below the depth of the plough.

5. In soils of a poor hungry quality, there should be some proportion observed between the depth of ploughing and the quantity of manure usually spread; but this does not hold good on better soils.

6. Soils are rarely found that ought not to be ploughed, in common, six inches deep; many ought to be stirred eight inches, and some ten.

7. One deep ploughing (to the full depth) should be given once in twelve, eighteen, or twenty-four months: if this be secured, shallow tillage is in many cases preferable to deep working oftener, especially for wheat, which loves a firm bottom.

EASY METHOD OF DISCOVERING WHETHER OR NOT SEEDS ARE SUFFICIENTLY RIPE.

An English publication assures us, that, "Seeds, when not sufficiently ripe, will swim, but when arrived at full maturity, they will be found uniformly to fall to the bottom; a fact that is said to hold equally true of all seeds."

SOAKING OF SEEDS.

"In dry seasons the soaking of seeds in water, a day or two before committing them to the ground will forward their growth, as well as by artificially watering the ground before or after sowing them; and the soaking of them in a solution of salt and water may have another advantage of giving an opportunity of rejecting

the light seeds, which float, and perhaps of destroying some insects which may adhere to them; the sprinkling some kinds of seeds with lime may also be of advantage for the purpose of destroying insects, if such adhere to them, and of attracting moisture from the air, or lower parts of the earth, or for its other useful properties; but where the seed, soil and season, are adapted to each other, none of these condiments are required.

It may nevertheless, on other accounts, be very advantageous to steep many kinds of grain in the black liquor, which oozes from manure heaps. Mr. Chappel, in the papers of the Bath Society, found great benefit by steeping barley in the fluid above mentioned, for twenty-four hours, and skimming off the light grains. On taking it out of the water, he mixed wood ashes sifted with the grain to make it spread regularly, and obtained a much finer crop, than from the same corn, sown without preparation. To this we may add, that to steep the seed in a solution of dung in water, as in the draining from a dung-hill, is believed in China both to forward the growth of the plant, and to defend it from a variety of insects, according to the information given by Sir G. Staunton.*

PRESERVING SEEDS.

Seeds of plants may be preserved, for many months at least, by causing them to be packed, either in husks, pods, &c. in absorbent paper with raisins, or brown moist sugar; or a good way, practised by gardeners is to wrap the seed in brown paper or cartridge paper pasted down, and then varnished over.

SOWING FRUIT WITH SEEDS.

When the fruit, which surrounds any kind of seeds, can be sowed along with them, it may answer some useful purpose. Thus the fruits of crabs, quinces, and some hard pears, will be all the winter uninjured covered only with their autumnal leaves, and will contribute much to nourish their germinating seeds in the spring.

Phytologia.

TO GENERATE THE BEST KINDS OF SEEDS

The most healthy plants must be chosen, and those which are most early in respect to the season; these should be so placed, as to have no weak plants of the same species, or even genus, in their vicinity, lest the fecundating dust of weaker plants should be blown by the winds upon the stigmata of the stronger, and thus produce a less vigorous progeny.—*ibid.*

A SUBSTITUTE FOR RINGING SWINE.

Mr. Tulb, an English breeder of stock, has recommended a mode of dealing with these mischievous animals, which it is said may supercede the necessity of putting rings into their noses. It consists simply in shaving off, with a razor or sharp knife, the gristle on the top of the noses of young pigs. The place soon heals over, and the pigs are thus rendered incapable of rooting.

BREEDING SWINE FOR SALE ON THE FOOT, FOR STORE PIGS, ROASTING PIGS, &c.

A breeding stock of Swine is said, by some writers on husbandry, to be more profitable to the farmer than keeping *fattening* stocks of the same animal. This will no doubt be the case on a dairy farm, as whey and skimmed milk

can, perhaps, be applied to no other purpose so profitably; and those substances are not sufficient to fat grown hogs for the market. The pigs may be sold at any time from three weeks to six months old, and their places supplied by fresh litters. A practice of this sort is recommended in Hunter's Geographical Essays, vol. vi. p. 183.

From the Old Colony Memorial.

In answer to the inquiry of Agricola, "Whether young apple trees are not sometimes destroyed by taking all their top branches off in the operation of grafting?" By nursery men, the operation of grafting is generally performed upon seedlings in the nursery while very small, and then the whole top is taken off without any injury or danger;* but when it is desired to change the fruit of a standard tree, or one that has attained nearly the size of bearing, the knife ought to be applied with caution—the head of the tree ought to be opened, by pruning the lateral branches of their upright limbs, so as to let in the light and air freely, and then cut off the leading branch, or the two leading branches, as there frequently are two, and sometimes three, and graft the desired fruit, leaving the lateral branches, at least one year, when you may graft one or more of the lateral branches as you may wish to form the head; and the second year you may with safety cut off the remaining superfluous branches—the necessity or utility of leaving on the lateral branches I conceive to be, the preservation of the circulation of the sap—in my own experience I have lost several trees by cutting off the whole head, and inserting several grafts at a time; I found they failed the second year by a sort of *conker*, beginning where the amputation was made, and descending so as to cut off all nutrition from the scion, while suckers would shoot up from the stump. I will not say that failure *universally* follows the cutting off the whole head at once, for I have seen it succeed in some instances, as I have travelled the road, but I have also seen many others that have failed. These facts are the result of many years experience and observation.

Yours,

P.

* There is a beautiful young orchard of about 250 apple trees in the town of Hanson, set out a few years since by its present owner, Charles Cushing, Esq. All the trees were grafted the two first years. The tops were wholly cut away; not a limb or sucker was spared. All the scions were set in the trunks of the trees. Not one of the number died, and the orchard is now remarkably thrifty, and no doubt fixes the eyes of travellers in that part of our country.

From the same Paper.

To the Editor—

Sir—In the New England Farmer, Sept. 7th, a writer over the signature of "A Farmer," refers to a publication in the O. C. Memorial, signed "Monumet;" advertizing to the destructive ravages of the worm upon the grass and corn in this vicinity. The Farmer regrets that Monumet, while announcing the enemy, did not attempt a description of him, and he observes, "If he has ascertained, that it was a worm, which produced this devastation, he might have described its length, its color, its first appearance, and duration. Is it the same worm which attacks the grass and the corn? A worm that

should destroy, or injure Indian corn in August, must be an important enemy, and should be described."

To supply the deficiency of Monumet, and in some imperfect manner to meet the desire of the Farmer, I will attempt a description of the worm, and as far as facts will enable me, its first appearance; its duration cannot be ascertained, (for it continues in full activity at the present time,) nor as yet, its generation, or its habits.

The worm was first discovered about the middle of June, its presence was suspected from the sickly appearance of the corn, about the time of *half killing*, the leaves turned red and wilting. On examination the worm was found depredating on the fibrous roots. It was then about three quarters of an inch in length, it has continued increasing in size until it has attained the length of one inch and a quarter or half. I shall not attempt a scientific description, but perhaps I may be able to make myself understood by those who have made natural history their study—its colour is white or a yellowish white, except the exterior part about one third its length appears bluish, from the contents of the abdomen, which, when emptied, is wholly whitish. Its head is large and beetle-shaped, copperas-yellow, near its mouth are two horns, similar to those of the beetle, but not so large in proportion to its size, immediately over these were a pair of *antennae*. I could discover no eyes on each side—on the anterior part, are three principal legs, resembling (when viewed through a microscope) those of a crab or lobster and are placed within an eighth of an inch of the head—forward of these, and near its mouth, are two smaller legs, similar in appearance to the other, but of which he makes no use in moving, but appear to be placed so as to assist him in conveying food to his mouth; the rest of his body is without legs, and in moving is dragged along—the whole body consists of distinct folds, I did not count them, but I think there may be 10 or 12—the size is that of the largest goose-quill, or rather larger.

That it is "the same worm which feeds on grass and on the corn" is demonstrable, and on the *potatoes* also, which in some fields are more than half devoured.

With respect to its generation or its habits we have not had experience, or an opportunity to observe them, so as to form even a conjecture. In digging the earth last March, they were dug up three feet below the surface, and in digging a post-hole in June they were found two feet down. Their lodgment now, is about two inches below the sward, which may be separated from the earth and turned over like a carpet, and so numerous that in one instance 128 were counted on the area of one yard, in another 12 on a square foot.

They first made their appearance here in 1819, they did much damage then to the grass, especially pastures, but not to be compared to that of the present season;—and those fields that were devoured then, have nearly escaped now. In the spring of 1820, there was an unusual appearance of what are called the *May Bee*; the conclusion then was, that they were connected with these worms, but this theory wants confirmation.

Yours,

PLYMOTHEUS.

FOR THE NEW ENGLAND FARMER.

Extract of a letter from J. F. Dana, Professor of Chemistry in Dartmouth College, to the Editor, dated Sept. 17, 1822.

DEAR SIR,

I was pleased with the correspondence between Gov. Wolcott and Mr. Pomeroy, contained in your paper, which I received yesterday. The subject is one of great importance to the country.

The application of steam as a means of separating the glutinous matter from flax is suggested by Gov. Wolcott, and probably might be employed with the most decided advantage; but will it destroy the coloring matter? probably not; and the use of steam generated from alkaline solutions seems to be forbidden by the suggestion of Mr. Pomeroy, that alkaline leys destroy a cellular oil on which the delicate softness of the flax depends. I wish to inquire, why chlorine or oxymuriatic acid gas may not be employed? The objections to its use in common bleaching will not apply to its use in bleaching flax. Permit me to suggest its application in the following way. Let a convenient apparatus for *steaming* the flax be prepared; into the boiler from which the steam is generated, introduce a convenient vessel of sheet lead which shall contain the materials from which *chlorine gas* is produced, viz. sulphuric acid, manganese and common salt. Now when heat is applied to the boiler to produce steam, the leaden vessel which it contains and which is surrounded by water, will be also heated; steam, and chlorine gas will be formed at the same time; the former will dissolve the glutinous matter, and the latter will destroy the color, and both will pervade every part of the apparatus. Experiment alone must decide whether this suggestion is practically useful; nor do I know that it has not been tried, and found useless.

The *muriate of lime*, suggested by Mr. P. has no powers in bleaching, and it is stated by some writers, that it very much weakens the texture of *linen*.
J. F. DANA.

Agricultural Exhibition for the County of Essex, at Topsfield, on Wednesday, Oct. 2, 1822.

The Trustees of the Essex Agricultural Society, to encourage improvements in the Agriculture and Manufactures of the County, offer in premiums for the present year, more than *Six Hundred Dollars*. They have taken care to provide convenient accommodations, and from the increasing interest manifested in the subject, they anticipate a more interesting exhibition than in any preceding year.

All claims for premiums for Stock, must be entered with the Secretary, or Col. E. Wildes, of Topsfield, on the day previous to the exhibition.

All Animals and articles intended for exhibition or premium, must be presented to the officers of the Society, who will be in attendance to receive them, by eight o'clock, A. M.

The Ploughing Match will take place precisely at eleven o'clock. The trial of Working Oxen will follow immediately after.

At one o'clock, the members of the Society will dine together at the Topsfield Hotel. At two o'clock, the Reports of the Committees will be received and examined by the Trustees.

At half past two o'clock, the members of the Society will go in procession from the Hotel to the Meeting House, where an Address will be delivered by the Rev. Dr. Eaton, of Boxford. After this, the Reports of the Committees will be publicly communicated, and such other business transacted as the interests of the Society may require.

From the Columbian Centinel.

MR. RUSSELL.—As the farmers are blessed with an abundant crop, it is of the first importance to have it well harvested.

The present month has been uncommonly favorable to the harvesting of beans, onions, and potatoes.

I would recommend to those who have *beans* not yet harvested, to have them pulled and housed before all the vines are dead, and before there comes rain. For one bushel gathered in this way is worth two bushels which are left in the field till the rain swells them. It is a lamentable fact, that nearly one half of all the white beans, which come to market, have a shrivelled appearance, which indicates neglect in the harvesting. For if the rain does not swell the bean, after it becomes dry its surface will be fair and smooth, and the bean, when dried, will be soft and tender. They are then much more wholesome than if they had been exposed to rains.

Onions.—As soon as onions come to their growth, the tops and roots begin to dry, and they should be harvested. They should be pulled, dried a day or two in the field, and then housed, before the sun turns them green and makes them tough. For they will taste and keep much better than those which lie out till they take the second root and become weather-beaten.

Potatoes.—I presume every man has observed how much better flavored potatoes are in the month of August, and even to the middle of September, than at any other time of the year. The reason is obviously, because they are gathered before they have attained their full growth and before the vines are dead. Potatoes, therefore, should be harvested as soon as the vines begin to die, and then they will not have any disagreeable earthy and watery flavor. They may be placed immediately in the cellar and will not sustain any injury from their dampness, if the cellar doors and windows are left open in fair weather.

THE FARMER'S FRIEND.

From the New York Statesman.

Cotton.—Our readers will recollect that in the early part of the year several essays were published in the Statesman, under the signature of "Agricola," on the subject of cultivating cotton in this and the adjoining states. Our correspondent being desirous that a fair trial should be made, procured, at his own expense, from South Carolina and Virginia, several barrels of seed, which were deposited with the editors of this paper, and by his direction, gratuitously distributed to all who were disposed to try the experiment. We shall be glad to learn from those who have attempted the cultivation of cotton from seed received at this office, what success they have met with. We have seen some bolls taken from the garden of Mr. O. Parker, of Greenwich, on the 10th inst.

which had then opened, and which present fine specimens of cotton. The seed was planted about the 23d of April, and we have no doubt that the cotton in the garden from which these bolls were taken, will come to maturity before the warm season is over.

Poul-on's Philadelphia paper of Saturday says—Some cotton seeds were put in the ground at Camden, N. J. in May last, and on the first day of September, inst. a part of it was maturely ripened and fit to gather. As it was late in the spring when these seeds were planted, there cannot be a doubt but that this valuable plant may be successfully cultivated in the sandy soil of New Jersey."

From the Western Reserve Chronicle.

Quick Work.—The barn of Mr. S. Hutchins, a respectable farmer in Vienna, (Ohio,) was struck with lightning on the 23th July, and most of the hay and all the grain raised on his farm the present season were consumed. On the 7th of August, his neighbors assembled and erected a barn for him 36 feet by 26. They cut the timber, hewed, framed, raised, boarded, shingled, made and hung the doors, and a large load of hay presented to him, was unloaded in it before sunset of the same day.

Something Marvellous.—On draining off the water in the summit level of the canal this week for the purpose of removing the earth which had been deposited in it by the late freshet, large quantities of live *clams* were discovered in the bottom of it, the shells of some of which measured 7 inches in length, and were well proportioned. Persons who have partook of these aquatic sojourners of our place, represent them to be of "*most delicious flavor*."—The shells are of a greenish cast, and almost as transparent as glass.—*Sandy Hill Times*.

NEW ENGLAND FARMER.

BOSTON:—SATURDAY, SEPT. 21, 1822.

ON SAVING AND MAKING THE MOST OF MANURE.

(Continued from p. 55.)

The advocates for long manure, and the sticklers for short manure, in our opinion, are both right with regard to some of the points in controversy. As regards other matters in dispute, we believe the truth lies between them, and of course both parties are a little on one or the other side of it.

The better to comprehend the subject, and make those practical deductions, which may render its discussion useful, it may be well to take into view,

- I. The nature of the soil to which manure is to be applied.
- II. The crop which is immediately to succeed the application of the manure, and which it is principally intended to benefit.

I.—THE NATURE OF THE SOIL.

Manure must not only ferment, but be completely decomposed, before it can produce its *full* effects in the nourishment of plants, or in enriching the soil. The products of its fermentation are certain matters called gasses, factitious airs or elastic fluids. They are, principally, carbonic acid gas, hydrogen gas, and azote, or nitrogen gas. A dark colored liquid, of a slightly sour or bitter taste will likewise be formed; and if the process be suffered to continue for a sufficient length of time nothing solid will remain except earthy and saline

natter colored with charcoal.* "If a quantity of stable dung be piled in a heap, and freely exposed to all the varieties of weather, it soon heats and emits a constant stream of vapor. As the gasses are escaping it is constantly diminishing in weight and volume; and by the end of six months, if there has been alternate moisture and warmth, not above a fourth part of the original bulk remains to be spread on the field; and this is always a blackish earth, mostly of carbonaceous matter. All the other ingredients consisting of the hydrogen, and azote, with part of the carbon in the form of carbonic acid, are partly sunk in the soil, and partly blended with the atmosphere. I admit the latter are not lost in the general system of the universe: but carried with the winds, they combine anew with some living vegetable, or enter into some equally useful compound; but lost they are to the farmer beyond all calculation. They may enrich his neighbor's crop, or be mixed and entangled in the luxuriance of the forest, but they can never reward his labor, nor impart plenty to his harvests. The nutritive juices may have passed downward, and fertilized the spot which it covered, but the substance is evaporated, and as completely gone, as if it had been consumed by fire.†"

There can be no doubt but vegetable manure, as long as it remains unaltered in its texture, and without involving any of the products of putrefaction can have no other than a mere mechanical effect in making the soil loose, which, in dry weather, will prove rather injurious than otherwise. But if the putrefactive process is carried on, after the manure is spread, and covered in the field, its volatile products, before mentioned, will be imbibed by the soil, and yielded as they may be wanted by growing vegetables.

We know however, that some kinds of earth retard, and others put an entire stop to putrefaction. A very wet, or a very dry soil will prevent wood, straw, &c. from rotting. Some sorts of earth will turn vegetables to peat; and some will preserve even animal remains for centuries, as entire as Egyptian mummies. That wood will rot much quicker in some than in other grounds, on the same farm, is a fact known to every serving husbandman, who has ever made much use of what is called post-and-rail-fence. Is it not then very possible that the difference among agriculturists relative to long and short manure may have been caused by the different qualities of the soils to which their applications have been made? Perhaps the field, to which the conductor of the Farmer's Magazine applied dung and litter, which had been turned down fresh in the furrow, and appeared the next spring without any visible change" might have possessed some chemical qualities—some salts or acids which prevented the manure from rotting, and preserved it as it were in a kind of pickle for the behoof of posterity. Pure sand will preserve carrots, beets, &c. which are buried in, much better than loam; and we have doubts whether fresh manure would undergo much alteration if buried in sand, not mixed with other substances.—There can be no doubt but that suffering manure to lie till it loses any considerable part of its weight, before it is used, is not the way to make the most of it. On the other hand, it will, probably, be best to permit it to lie in masses, under cover as much as possible, till it becomes tainted, or fermentation has commenced, before it is spread and ploughed into the soil.

THE NATURE OF THE CROP.

In the choice and application of long or short manure, a suitable regard should be had to the nature of the crop, which immediately succeeds such applica-

tion. If used for crops of wheat, rye, flax, or in short any crops which cannot well be weeded, it should be old, well rotted, and at least have undergone so great a degree of fermentation as will have destroyed the seeds of grass, weeds, &c. which generally abound in fresh barn yard manure. Likewise when used for carrots, ruta baga, parsnips, and indeed all root crops, except potatoes, it should be fine, well rotted, or mixed in composts, which are so well pulverized as to present no mechanical obstacles, such as sticks, straws, or lumps of earth to the growth and extension of the roots. For Indian corn or potatoes however, it may be fresh, and if well covered in the soil, its being coarse and mixed with weeds, straw, &c. will not prevent its proving useful. It may be, however, that the soil will cause it to *dry-rot* like that mentioned by Judge Peters, or it will not rot at all like that of the conductor of the Farmer's Magazine. In such cases, it might not be amiss to try the virtue of a little quick lime. This substance, however, should not be applied directly to the manure, lest the latter be destroyed by the corrosive quality of the former. The quick lime should be applied directly to the soil itself some time before the application of the manure, in order to neutralize any acid which may be unfriendly to vegetation, or have a tendency to prevent the decomposition of the manure.

(TO BE CONTINUED.)

CATTLE SHOWS, &c.

The Cattle Show and Exhibition of Manufactures of the Middlesex Husbandmen and Manufacturers, will be held at Concord, Mass. on the 3d of Oct. next.—The Hartford, Conn. Cattle Show, on the 9th and 10th of October.—The Agricultural Society of Maine, will hold their annual Show and Fair, on the 9th of Oct. at Hallowell.—That of the Rhode Island Society for the encouragement of Domestic Industry, at Pawtuxet, on the 16th and 17th of Oct.—The Hampshire, Hampden and Franklin, at Northampton, Mass. on the 24th and 25th of October.—and the Hillsborough, N. H. Cattle Show and Fair, at Amherst, on the 24th and 25th of the present month.

Foreign.—On the 7th July the Ministers and Agents of Russia, Austria, Prussia, France, Denmark, Saxony, Portugal, and the Netherlands, all united in a Note to the Spanish Ministers, in which they declare, in the names of their respective Sovereigns, and in the most formal manner, that "on the conduct which will be observed towards his Catholic Majesty, irrevocably depend the relations between Spain and the whole of Europe, and that the least insult to the King's Majesty would plunge the Peninsula into an abyss of calamities." The British Minister did not join in this peremptory note, but sent a special one, the contents of which are not given.—*Centinel.*

The war between the Greeks and Turks still rages with unabated fury. The Greeks have lately blown up a Turkish ship, by the means of a fire ship intended for the destruction of two of the principal vessels of the Turkish fleet. The vessel which was thus destroyed carried 30 guns, and had a crew of 1700 men, of which about 300 only were saved, the rest having been blown to atoms with the ship.

A dispute between Spain and Algiers on the subject of tribute threatens to terminate in hostilities.

A successor to Mr. Gallatin, at the Court of St. Cloud, is daily more spoken of, since his speedy return to America has been positively announced. It is rumored that the appointment will be offered to Secretary Calhoun.

Francis Dugan, one of the prisoners so desperately wounded by Frask, in our jail, on the night of the 6th inst. is dead of his wounds. Newman, the other person who was wounded at the same time, it is supposed cannot recover.

Naval Combat.—Capt. Bourne, of the brig *Hippomenes*, arrived at New York in 16 days from Curacao, states that a brother-in-law of Dr. Quackenbush, of this city, arrived at Curacao on the 22d ult. in a schooner from St. Thomas, which place he left on the 15th of August, under convoy of the U. S. schooner *Grampus*. This gentleman informed, that the same evening he sailed from St. Thomas, the *Grampus* was dogged several hours by the privateer *Panchetta*, of Porto Rico—that in the morning the *Grampus* gave chase to the privateer, then under English colors, afterwards changed to Spanish. After being hailed, and informed of the character of the *Grampus*, the privateer fired a broadside into her. The *Grampus* then sheared alongside, and put a full broadside into the privateer, when she immediately surrendered, was boarded, and found in a sinking condition, with eleven men killed and wounded. The *Grampus* towed her into St. Thomas the same night. The *Panchetta* mounted 3 twelve pounders and a long tom, and had 92 men.

N. Y. Statesman.

Election in Vermont.—Although all the returns of votes for Representatives to Congress had not been published at the date of our last accounts from that quarter, there is but little doubt but that Messrs. R. C. Mallary, Charles Rich, S. C. Crafts, D. Azro A. Buck, and W. C. Bradley are elected.

By the last accounts the Yellow Fever continues at New York with unabated malignity.

Boston Cotton.—Several beautiful Cotton Trees are now ripening at Doct. Wakefield's, and at Mr. S. A. Shed's, in Milk street. Some of the trees contain more than a dozen pods, and are worth the attention of the curious to examine them.

Mr. Ware, of Salem, has this year raised a water melon weighing over forty pounds, and several weighing from 30 to 40.

Mr. Israel Putnam, of the same town, picked an apple from his garden a few days since, which weighed one pound five and an half ounces!

Green Corn in September.—Last Saturday, Indian corn in the milk, raised from Alabama seed, by a person in Cranston, was sold in our market at 20 cents a dozen. On an ear of average size we counted 18 rows and 846 kernels. Our gardeners will consult their interest by the cultivation of this new variety, as it comes in when peas, beans, and the ordinary kinds of corn are out of season.—*Providence Journal.*

Worcester Canal.—We learn from a gentleman who has been on the route now under survey, that the whole descent, from Worcester Great Pond to Woonsocket falls is found to be 450 feet. This is much more than was anticipated, and must enhance, considerably, the expense of the work. Another circumstance, however, appears very favourable. On the route, as far as it has been surveyed, the excavation will be very easy, as but little rock is found near the surface.—*ibid.*

Water Spouts on Lake Erie.—Yesterday about ten o'clock, A. M. (says the Cleveland Herald of Aug. 22,) while a cloud hung over the lake, apparently at the distance of about ten miles, the people of this village were entertained at the sight of several water-spouts, which formed themselves, one after another, from the lake to the cloud. They were four in number, of different sizes, and a considerable distance from each other. The cloud being high, and the spouts being black and perpendicular, resembling huge pillars of some mighty fabric, and occasionally changing in their positions, presented a prospect both grand and beautiful. They continued visible for some length of time, and their disappearance was followed by the falling of rain in torrents on the lake, and a slight shower extending itself to this village.

A gentleman in Perth, Scotland, has a hen which lately hatched 20 chickens out of 13 eggs!

WANTED IMMEDIATELY,

A N active, intelligent Boy, 15 or 16 years of age, as an Apprentice to the Printing business. Inquire at the Farmer Office. Sept. 21.

A MAN TO MY MIND.

Since wedlock's in vogue, and old maids little priz'd,
To all bachelors greeting, these lines are premis'd;
I'm a maid that would marry, but where shall I find,
(I wish not for fortune) a man to my mind.

Not the dandy, who's hardly of masculine race,
In love with his own precious figure and face;
Not the free-thinking rake, whom no morals can bind,
Neither this nor the other's the man to my mind.

Not the ruby fac'd sot that tops, world without end,
Not the drone, who can't relish his bottle and friend,
Not the fool that's too fond, nor the churl that's unkind,
Neither this—that—nor t'other's the man to my mind.

But the youth in whom merit and sense may conspire,
Whom the brave must esteem, and the fair should admire;

In whose heart love and truth are with honor combin'd,
This—this—and no other's the man to my mind.

A MAN NOT TO MY MIND.

From the man whom I love, though my heart I disguise,
I will freely describe the wretch I despise;
And if he has sense but to balance a straw,
He will sure take the hint from the picture I draw.

A wit without sense, without fancy a beau,
Like a parrot he chatters, and struts like a crow;
A peacock in pride, in grimace a baboon,
In courage a hind, in conceit a gascoon.

As a vulture rapacious, in falsehood a fox,
Inconstant as waves, and unfeeling as rocks;
As a tyger ferocious, perverse as a hog,
In mischief an ape, and in fawning a dog.

In a word, to sum up all his talents together,
His heart is of lead, and his brain is of feather;
Yet if he has sense but to balance a straw,
He will sure take the hint from the picture I draw.

MISCELLANEOUS.

LADIES—BEWARE!

[The following will serve as a caution to females, against the impositions which are often practiced upon them, to their mortification, shame and ruin. Let them prefer, as suitors and husbands, those whose characters and circumstances are known to them, and not trust to the oily tongues, and vain pretensions of foreigners and strangers, who, under the disguise of a fine dress, and genteel manners, often conceal the most villainous designs.]—*Salem Register*.

Reported for the Philadelphia Union.

A European, who had a wife and several children in his own country, not thinking himself well treated by his wife's family, determined, as soon as he could compass fifty pounds, to try his fortune in America. After he arrived in Philadelphia, reflecting that he was a great way from home, and that many circumstances might happen here which would never be heard of in Europe, he changed his name and took up his abode at a hotel, where his fifty pounds were soon reduced to 1 dollar 13 3-4 cents. He then thought it time to look out for other quarters, and accordingly removed very quietly to a private boarding house, where a fine young woman soon attracted his attention. In due time she consented to become his bride, and the marriage ceremony was properly solemnized.

Hitherto nothing had occurred to give reason to suppose that our gentleman was any how different from what he professed to be, unless it were an odd letter which was now and then picked up about the house, addressed to Mr. D.

O. S. but which excited more amusement than suspicion. On a certain day, however, when he walked out with his bride, he was met by a countryman of his, who, after accosting him with great familiarity, enquired after the health of his wife and children. Our gentleman returned the salutation with cordiality, but perceiving his fair companion was alarmed by the interrogation, he abruptly broke off the conversation with the stranger. The rest of the afternoon was spent in accounting to the lady for the strange scene which he had lately witnessed. Inquiring after the health of the wife and children of unmarried men was, he said, a very common joke in his own country, and she, having an interest in being deceived, believed him.

His countryman, however, offended at the abruptness of his conduct, dogged him home, and a few days afterwards called to enquire for him by his real name. The letters were then remembered, and the fears of an old lady in the family so alarmed, that she laid information before a magistrate, who sent an invitation to our gentleman to appear before him. "Ah!" said he, after he had read the summons, "another invitation to dinner. Upon my honour, if I could eat fifty dinners a day I might have them all. However I shall accept of this, as I know the giver is a good kind of a fellow." He went accordingly, and, though surprised to find his wife and some of her relations there before him, still had the effrontery to offer the magistrate his hand. This the latter refused to receive till he had read the charges against him—bigamy and imposition. "Good God, Sir," said our gentleman, "don't stain my honor with such imputations. Allow me till to-morrow and I will produce letters and witnesses that will avouch for my respectability." The magistrate, after consulting with the parties agreed to this arrangement; but that night our gentleman disappeared and has not been heard of since.

From the New York Statesman.

"*Love has eyes*."—The Westchester Herald states, that a villain of the name of William Rosler, was detected in robbing the store of Michael Marks, by a young lady and gentleman who, as the term goes, were *keeping company* in the house opposite the scene of burglary. While they were prolonging their midnight vigils, indulging in some wakeful dreams of nuptial felicity, they saw the villain enter the store through the window, and when he was cleverly in, young Damon stepped across the road, made all fast, and gave the alarm, which resulted in the easy apprehension of Rosler.—The paragraph cautions all robbers to beware of attempting depredations *between the hours of ten on Sunday evening, and day-break on Monday morning*, which is "the witching time of night" with village lovers. Fortunate would we be, if we had guards equally wakeful in the infected district.

Old Seed.—However valuable ancestry may be in the eye of a man of family, it is in little estimation in that of farmers, if we may judge by the reply a country lad made to one who was boasting of his *ancient family*. "So much the worse for thee"—said he—"every body knows the older the seed, the worse the crop."

From the American Statesman.

The Office of the Philadelphia *Union* lately took fire. The manner in which the accident occurred is very pleasantly related in the following paragraph, which subsequently appeared in that paper:—

"The report which the wags are circulating that the fire at our office on Thursday evening originated in the spontaneous combustion of a number of political articles of a highly inflammatory character, is totally destitute of foundation. We do not deal in such dangerous ware. The truth is, that our 'devil' was endeavoring to purify a number of communications by fire, but not being careful enough of the process, the flames unfortunately spread to a number of poems in manuscript, (the collections of the last two years,) which, by reason of the *spir* contained in them, made a fine crackling blaze and finally exhaled in fumes ethereal. The went off in a most glorious smoke, but burned so furiously at first as to scorch the wainscoting of the room, and burn a hole through the floor. We trust that our poetical friends will now see the propriety of not burdening us in future with so many *original verses*. We always consider them very dangerous articles."

MR. BRAHAM, THE SINGER.

It is reported that this stage songster is about to honor us by leaving England to sing for *one year*, for the moderate sum of *forty thousand dollars*! The editors of the National Intelligencer, noticing this matter, have observed, "we shall be glad to hear what our friend Niles will say to this folly." All that is needful to say easily said—"friend Niles" pays nothing England for his *coats*, and will not pay any thing to *transient* Englishmen for *songs*—though pleased to hear good music on rightful occasions at reasonable terms. Yet the managers of our theatres may make money by exposing the musical biped to the public—and persons will spend ten or twenty dollars to hear him, will have defrauded their honest creditors out of scores of thousands, or suffer themselves to be *dunned* by those who supply them with *milk* for their coffee and tea. It is even yet *à la fashion* rather to be extravagant than to be honest—though the state of society is evident improving; more perhaps, of necessity, than from inclination.—*Niles' Register*.

JUDICIAL PLEASANTY.

A lawyer, now deceased, a celebrated wag, was pleading before a Scotch Judge with whom he was on most intimate terms. Happening to have a client, a *female*, defendant in an action of the name of *Tickle*, he commenced his speech in the following humorous strain:—"Tickle my client, the defendant, my lord." The auditors, amused with the oddity of the speech, were almost driven into hysterics of laughter by the Judge replying—"Tickle her yourself Harry; you're as able to do it as I."

LA FONTAINE.

A worthy Antiquary was one day edifying the French academy with a monstrous long dissertation of the comparative price of commodities at different periods, when La Fontaine observed "cet homme censure le prix de tout excepté temps."—"This man knows the price of everything except *time*."

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I.

BOSTON, SATURDAY, SEPTEMBER 28, 1822.

No. 9.

CONSIDERATIONS ON THE NECESSITY OF ESTABLISHING AN AGRICULTURAL COLLEGE,

and having more of the children of wealthy citizens educated for the

PROFESSION OF FARMING.

(Concluded from p. 53.)

What the precise construction, organization, and discipline of the agricultural college ought to be, I shall not at present presume to define. They ought to be well digested in the outset, but whatever may be the wisdom engaged in it, like all other institutions, time only can bring it to perfection. Experience must teach what will finally make it what it ought to be, to answer all its intended purposes. The outlines of it only can now be attempted.

As usual, its concerns will be committed to a board of trustees. Its faculty will consist of a president and professors of the several branches to be taught, the chief of which will be one for the theory and another for the practice of agriculture, besides others for such appendant branches as may be judged necessary, particularly chemistry and botany. What the business of each is to be may be easily conceived, except that of the professor of practical agriculture, who is to be literally what the title imports, and whose duties it may not be amiss more minutely to consider, as it is he who is to make him, who is previously or simultaneously instructed in the necessary scientific parts, the perfect practical farmer.

Much will depend on the choice of this professor. He should himself understand all that relates to the theory, and besides have been so far engaged in the actual practice of farming as to be thoroughly acquainted with all the methods already successfully adopted. He must be capable of making all prescribed experiments in the best manner, and of stating true comparisons between their results and the customary practice: He must know how to make all the arrangements for the work to be done, and direct every part of it to its proper end, so as to produce the best and greatest effects with the least loss of time. On this faculty more depends than is generally conceived; for it is a well known fact that by skillful management one person will obtain much more from his laborers than another, although both may in other respects understand their business equally well.

This professor will of course have the superintendence and direction of the labor of the students in the field. What will be required of them there next demands consideration. It has already been observed that they must learn to work; and this is to be an essential object of the institution, for without knowing how to perform, with their own hands, every kind of work belonging to the profession they intend to pursue, they never can become sufficiently acquainted with it or qualified to conduct it to advantage.

It will be readily perceived that to such an institution must belong a farm of sufficient extent and variety of soil for all the practice and experiments that may be required to carry its views into the completest effect; and this farm

is to be made not only instructive, but, if possible, profitable also. For certain regularly allotted portions of time, the students are to be employed on it and practice every species of work that may be requisite; such as plowing, harrowing, sowing, planting, reaping, hay-making, threshing and preparing every thing for market; and they are to be practically instructed in the selection, qualities, management and value of cattle; in short in every thing with which a farmer ought to be thoroughly acquainted, and which he ought to be able to do.

Instead of giving formal lectures, this professor, who must constantly attend his classes while thus engaged, will, during the progress of their work, explain to them the best manner in which every thing is to be done, the reason of it, and the errors that are or may be committed in it; on all which, the students will be required to make notes and comments at their hours of relaxation, and undergo examinations at stated times. And as hired laborers will besides be necessary, the very best should be selected to give examples of the most proper manner of performing every branch of business, and of the time in which it can and ought to be done.

The knowledge of gardening, inoculating, grafting, and the best manner of propagating fruit trees and shrubberies, will also be taught by engaging the students in the same way in actual practice.

Every farmer ought to be able to repair his implements when out of order, without suffering, on every such occasion, the loss of time and expense to which the sending for the proper mechanic would subject him. A workshop provided with all necessary tools will therefore properly be a part of the establishment. Some exercise here will give to all the students an agreeable variety of employment, and to those who have a mechanical turn it will be as gratifying as useful. Here also ought to be collected models of all the best implements of husbandry, of which the respective merits will not only be explained by the proper professor but proved by actual trial.

Books will be kept in which will be entered in detail, all the transactions of the farm, and periodical statements of results, with account of profit and loss; and these the professors may make the subjects of useful and profitable lectures.

Public examinations on theory and practice, and exhibitions of work will be appointed, honors awarded and diplomas given as evidences of superior merit on a completion of education. And these when justly estimated, as undoubtedly they will be, must give title to a precedence before those who hold licences for following any of the liberal professions.

Here will also be taught, both by precept and example, that frugality, temperance and economy, of time as well as of expense, which are equally essential with skill in the profession for its successful prosecution; lessons of the utmost importance to those young gentlemen who may have been contaminated by the customs of cities; customs, which besides fostering idleness and dissipation, prescribe innumerable costly

delicacies, as useless to adults as pernicious to children. And it is sincerely to be regretted, that so many of the farmers of our country depart from a better manner of living for the purpose of aping, in an awkward way, the more irrational style introduced, partly by necessity, and partly by a ridiculous vanity, among the inhabitants of cities. By such frugality and economy will be taught the secret, of possessing, at all times in abundance, the means of a better living than such citizens enjoy; if by better living be understood what is more according to nature, more highly relished by an unvitiated palate, and more conducive to health, the *bona qua non* of every enjoyment.

It is well known that there are men laboring under an incurable infirmity, or delicacy of constitution, for which is assigned, as the most probable cause, their having been pampered, when young, with fashionable dainties. To have the effects of such practices corrected, as early and as effectually as possible, is therefore, to any such unfortunate individual, a matter of the highest importance, and to do this will be one, among the many other good offices of the proposed institution. Foreign luxuries will be discarded, and the food will be, as it ought to be, with every agriculturalist as far as possible, the sole produce of the farm, and that will be made, independent of all other sources, to yield in abundance, all the prime luxuries of life.

* * * * *

If cheering or exhilarating beverages are necessary, and some thing of the kind seems, from the practice of all ages, to be allowable, if not actually beneficial, while reason does not condemn their use in moderation, we have them of the most innoxious kind and the most grateful variety, without resorting to places beyond our own territories for them. Our cider, were it not for the unaccountable prejudices of taste, would be deemed superior to the ordinary wines of Europe; and every family, with a little instruction in the process, could make its own beer of sufficient excellence, or it might be had from the best brewers by a ready exchange of produce. To send our money abroad for any such luxuries cannot then be considered otherwise than as a wanton waste of property and a mistaken apprehension of what is necessary to support true dignity of character.

A family of middling size will, in the course of a year, use thirty-five dollars worth of coffee, and probably its tea and sugar for suppers will cost as much, making seventy dollars. This is a serious sum to be paid every year for mere luxuries by any farmer and especially by new beginners: It is the interest of one thousand dollars, for which a little farm might be bought and many a good one rented. But this is only a part of the useless expenses of our countrymen. Add to it what is laid out for spiritous liquors without taking into the account unnecessary fineries of foreign manufacture, and many other useless items, and the amount will appear still more serious.

If any thing can be done towards this reformation by the agricultural college, thus second-

ed by agricultural societies. the immense good it may do even in this incidental branch of its objects, presents its importance in a point of view that must still more forcibly arrest our attention.

Here an enchanting picture might be drawn of the happiness which will intermingle itself with the little hardships of the tasks to be performed by the young gentlemen that shall fill such a college; tasks which, notwithstanding the sternness of their aspect, as portrayed in this treatise, will, by habit, have every repulsive feature obliterated, and become attractive by the group of pleasures that will, on a more intimate acquaintance, be found playing around them; but enough has already been said to give an idea of what the *agricultural College* is intended to be, and what may be expected from it. I shall take leave of the subject by recommending it to the serious consideration of the legislature, confident that, if it be deliberately examined, there will be a unanimous disposition to give it a *being*, and a *support* commensurate with the importance of the purposes intended to be effected by it.

BRIGHTON CATTLE SHOW.

Rules and Regulations to be observed at the Cattle Show, Exhibition of Manufacture, Ploughing Match, and Public Sale of Animals and Manufactures, at Brighton, on Wednesday the 9th, and Thursday the 10th of October, 1822.

I.—As the Names of the Committees for awarding Premiums will be published, all persons having business will attend their own Animals or Articles, at 9 o'clock each day, as it is intended that the Committees should commence their examination, punctually, at that hour; and at 1 o'clock, on Wednesday, the 9th Oct. a procession will be formed in the spaceway between the Pens, by the Marshals, and will proceed to the Meeting House, where Prayers will be offered, and an Address delivered by the Hon. TIMOTHY PICKERING.

II.—All Stock, entered for Premium, must be put in the Pens at 8, A. M. according to the numbers on their Tickets, as furnished by the Clerk, and under the direction of the Marshals.

III.—Gentlemen who have *Fine Animals*, not intended to be offered for Premiums, will gratify the Society by exhibiting them in their Field, where Pens will be allotted to them, subject to the same rules with those who contend for Premiums.

IV.—No Animal can be removed from the Pens but by permission of a Marshal or Trustee.

V.—The avenue between the ranges of the Pens, is intended exclusively for the *Trustees, Committees, Members of the Society*, and invited persons; it is therefore requested and expected, that no other person enter the same, but at the invitation of one of the Trustees; but the *Field* will be free to all.

VI.—All Articles, under the head of "*Domestic Manufacture*," it must be carefully noticed, are to be deposited in the Society's Rooms, on Monday the 7th, to be examined by the Committee, on Tuesday the 8th, *being the day before the Cattle Show*. Persons offering them, will hand to the Secretary, the necessary Certificates of the growth of the Wool and Flax, and of the Manufacture, being within the State of Massachusetts, as they are not permitted

themselves to be present at the examination by the Committee; but they are expected afterwards to see to their own goods, which are not allowed to be removed from the Hall, until after the public sale on the 10th.

VII.—All persons offering Articles under the head of "*Inventions*," will place them in the Lower Hall, as directed by the person who will be there to receive them, on *Tuesday the 8th, and on Thursday the 10th*, at 9 A. M. they will attend the Committee, furnished with evidence of their usefulness, &c. agreeably to the premium list.

VIII.—Those persons offering *Working Oxen*, (having regularly entered them,) will arrange them in the Society's Field, under the direction of a Marshal, and must thereafter be under the direction of the Committee for that purpose.

IX.—Those persons, who have entered *Ploughs for the Match*, will have them in the field designated for that purpose, and be ready to start at 9 A. M. of the 10th.

X.—The following Gentlemen being appointed Marshals, Col. LESHUR GAY, Maj. WHEELER, W. TILESTON, and G. W. BEALE, Esq's. it is expected that every person having business at the Show, will follow their directions, as also those of the Trustees of the Society, so that proper order and regularity may be supported.

XI.—As the Chairman of each Committee will prepare their own Rules and Regulations, it is expected and required, that all persons having business with either Committee, will govern themselves accordingly.

XII.—The Premiums will be awarded on the 10th, at 4 P. M. in the Meeting House; and the Treasurer will immediately after, in the Society's Hall, pay all premiums awarded to persons living more than ten miles from Boston; and all others are requested to call on him within ten days.

XIII.—The examination of *Animals*, will be on Wednesday the 9th, and the trial of *Working Oxen*, the *Ploughing Match*, the examination of *Inventions*, and the sale of *Animals and Manufactures*, will be on the 10th of October.

XIV.—All Fat Animals must be weighed before entering the Pens, at the expense of their owners.

XV.—Animals to be sold at Public Auction on the 2d day of the Show, (agreeably to notice in the Hand Bill for Premiums,) must be entered, and a description of the same given the Secretary on the 9th, to enable them to enter the proper Pens, on the morning of the 10th; the sale whereof, will commence in regular order at half after 11 o'clock, precisely. An Auctioneer will attend to the sale, free of charge to the owners, who must be responsible for the delivery of their own Animals, in conformity to the conditions of the sale. The sale of *Manufactures* will commence in the Hall, at 12 o'clock. Proprietors of Goods will have a list prepared to hand to the Auctioneer; they are also expected to collect their own monies; it being fully understood, that the Auctioneer is only to *bid off* the same, free of any expense; and the sale will commence with the first entry, and proceed on regularly.

XVI.—Any Members of the Society who have not received their Certificates, will find a person attending for that purpose, at their Office in the Agricultural Hall, who will deliver them, on payment of Five Dollars, the sum agreed

upon instead of all annual assessments. The same person will also, on application in season, furnish Tickets for the Dinner.

XVII.—The Hall will be opened, on Wednesday the 9th, between the hours of 9 and 12, for the sole purpose of giving Ladies an opportunity of viewing the Manufactured Articles. Some of the Trustees will be there to wait upon them.

GORHAM PARSONS,
JOHN PRINCE,

FACTS AND OBSERVATIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY.

TO MAKE SALT BUTTER FRESH.

Put four pounds of salt butter into a churn, with four quarts of new milk, and a small portion of aratto; churn them together, and in about an hour, take out the butter, and treat it exactly like fresh butter, by washing it in water, and adding the customary quantity of salt. Firkin butter, brought in autumn, and churned over again in winter or spring, will be greatly enhanced in value; at least so says the Domestic Encyclopedia.

AXIOMS IN HUSBANDRY.

The following maxims are by Thomas Cooper, Esq. M. D.

1. Two crops of grain should not succeed each other; they should be separated by potatoes, clover, grass, turnips, beets or carrots, for stall feeding.

2. Good agriculture requires no naked fallows: fallow crops [any hoed crops] that compel you to keep the ground clean while they are growing, answer the purpose.

3. Manure once in four years.

CURING TAINTED MEAT.

Meat which has been kept too long in summer may be deprived of its bad smell by putting it in water, and throwing into the pot, when beginning to boil, a shovel full of live coals, destitute of smoke; after a few minutes have elapsed the water must be changed, when the operation, if necessary, may be repeated.

PRESERVING MEAT.

Meat surrounded by charcoal will keep for months.

BED BUGS.

The last American edition of Willich's Domestic Encyclopedia contains the following recipes against those nauseous insects:

Take of the highest rectified spirit of wine, half a pint; newly distilled spirit of turpentine, half a pint; mix them together, and crumble into it an ounce of camphor, which will dissolve in a few minutes; shake the whole well together, and with a piece of sponge or brush dipped into it, anoint the bed or furniture in which those vermin harbor and breed, and it will, infallibly, destroy both them and their nits.—Should any bug or bugs happen to appear after once using it, the application must be repeated, and at the same time some of the mixture poured into the joints and holes of the bedstead and head-board. Bedsteads that have much wood work require to be taken down before they can be thoroughly cleansed of these vermin; but

others may be perfectly cured without that trouble. It is advisable to perform this work in the day time, lest the spirit contained in the mixture take fire from the candle, while using it, and occasion serious damage.

2. Dissolve 100 grains of corrosive sublimate in a pint of brandy: use it with the feather of a quill.

3. Half an ounce of corrosive sublimate, powdered and dissolved in a quart of spirits makes an effectual wash for bedsteads infested by bugs. They must be previously scrubbed with cold water and well dried.

In England, cast iron bedsteads are much in use for hospitals, &c. and are recommended as affording no harbor for vermin.

THE BREEDING OF CATTLE.

Dr. Cooper, Editor of the last American edition of Dr. Willich's Domestic Encyclopedia, observes that—"The whole art of breeding animals and vegetables for particular purposes, may be included in the direction, *choose those animals or vegetables to propagate from, that possess the qualities you wish to propagate in the greatest perfection.*"

To destroy the bee miller.—This troublesome insect is making great ravages among the bees in this vicinity. A subscriber has requested us to state that he had discovered an effectual method of destroying them, which is as follows: To a pint of sweetened water, (sweetened with sugar or honey) add a half a gill of vinegar; set this in an open vessel on the top of the hive; and at night, when the miller comes to his work of destruction, he will prefer this composition, and diving into it, will immediately drown.—This simple method, our informant assures us, is certain of success. At all events it is worthy of attention; and we would recommend to the owners of bees to make a trial of it.—*Lake George paper.*

From the Old Colony Memorial.

SIR—The inquiry, which has been instituted in the Memorial respecting the worms which are making such devastation of the grass and Indian corn, and the observations consequent thereof, have drawn so much attention to the subject, as to ascertain, that this is not "a new thing under the sun." In the annals of the Cotton Family (one of the most respectable in the Commonwealth) which have been continued from the first settlement of the country, are noted many extraordinary events and seasons (extraneous of the concerns of the family:) among others it is there noted, that "1745 was remarkable for the destructive effects of the worms which almost destroyed the grass." There is also now living in this vicinity, a respectable farmer, aged 87, who well remembers that when a boy, he with others, amused themselves by rolling up the sward, which was destroyed by the worms, striving who could make the largest roll—allowing this man to have been 10 years old at that time, and it reduces it to 1745, the period noted in the annals; and he further states, the worms were of similar appearance of those now present.—There are also others who state, that a year during the revolutionary war they made great ravages both in the corn and grass. From these facts perhaps it may be inferred that their appearance is rather period-

ical than extraordinary, and if the different times of their appearance had been all observed and noted, with the precision they are in the annual above alluded to, we might perhaps, ere now have ascertained the period of their expected return, and possibly some means of counteracting or limiting their ravages. The greatest advantage perhaps that may now be expected to be derived from the attention excited to this subject, is the obtaining more minute observations of the times of their appearance—the time of their continuance—and, if possible, the manner of their reproduction, and whether their appearance is consequent of a season remarkable for drought.

Yours, P.

A gentleman of this town (Plymouth) has constructed a drill for the purpose of sowing Ruta-Baga or other small seeds, which embraces the two great points of cheapness and simplicity. It may be constructed by any farmer of ordinary mechanical ingenuity with his hand-saw, hatchet, and knife; it can be worked by a boy 12 years of age, and does the work with neatness and dispatch.—*ibid.*

Camphor trees.—These trees grow in the I-land of Sumatra. A letter from a traveller published in an Edinburgh Journal, describes them as being often 100 feet perfectly straight to the first branch. The camphor is found in masses, in cracks and hollows in the heart of the tree. It is chiefly carried to China, where it bears a price about 30 times that of the China camphor. It is the latter that is brought to Europe and America. It is obtained by boiling. The Sumatra camphor tree also yields a powerful oil. It flowers only once in four or five years.

Hampshire Gazette.

Divining Rods.—It is stated in an extract published in the Palladium, that a piece of gold, silver, or any other metal, suspended to the end of a very slender switch, when carried over a mine of the same metal, will be so attracted as to bend the end of the stick. The writer tried an experiment with a pair of curious scales. He put a shilling piece of silver into one scale and made the beam perfectly level by weights in the other; a block of silver, 6 inches square and two inches thick, was then introduced under the scale that had the shilling; that end of the beam dropped a quarter of an inch, and stood there until the block was removed and then immediately returned to a level: this was repeated several times with the same effect.

ibid.

The Cotton Manufactory, at Waltham, is owned by gentlemen of Boston, and is unquestionably the most extensive of any one in the United States.—We have heard it stated that the capital is six hundred thousand dollars. About 500 workmen are employed, (but few boys or girls,) nearly all of whom are Americans. The weekly expenses are about 2000 dollars, which amount to upwards of one hundred thousand dollars in a year. There are manufactured thirty-five thousand yards of cloth in a week, or in a year, one million eight hundred and twenty thousand yards! which cloth, for shirting and sheeting, is daily gaining credit in every section of the Union. The machinery, too, is in many respects

superior to the English; so that this extensive establishment may emphatically be styled the pride of America.—*Boston Gazette.*

From the New York Commercial Advertiser.

"———But who is she,

Her dark hair streaming on her brow, her eye Wild, and her breast deep-heaving? She oft gaz'd At distance for the white sail, nor wept, nor spoke, And now is gone."

A coroner's inquest was held at West Point on Thursday, on the body of a woman named ————McGinn, who was found dead among the rocks at the foot of the high cliff which overhangs the favorite retreat or grotto of Kosciuszko, where that officer was wont to regale himself and friends with wine, after dinner, while stationed there during the revolution. The verdict accidental death.

The circumstances that have marked the life of this humble woman, and her now unlappy husband, have been in some respects romantic; and her conduct since her marriage, has afforded one of the strongest examples of constant and ardent affection. And what is most remarkable is, that it was the intensity of her affection that caused her untimely death. It appears that they were acquainted in Ireland, but as no peculiar attachment existed between them, they emigrated to this country separately and at different times. By accident they met, either at West Point or near the Foundry on the opposite side of the river, a few years since; soon after, it was agreed that they would be married whenever Patrick should have raised a certain sum of money. Patrick then went away and labored hard and lived prudently, until he had accomplished that object, when he returned and was rewarded for his toil by the heart of the object of his affection. Their lot was cast in the humble walks of life, it is true, but never did a couple live more contented and happy than they. And whenever Patrick has been called away on business, it detained longer than was anticipated, she knew neither rest nor slumber until his return. It is but a short time since Patrick went to Newburgh in a boat, where he was detained all night, and such was the faithful wife, that she sat upon a cliff that overhangs the river, or walked upon the edge of the rugged steep, until the boat came safe to the shore in the morning. And often has she counted the solitary hours, as they passed tediously on, in the same manner, while no sounds broke upon the dull hours of night, save the howling of the rude winds above, and the dashing of the surge against the rocks below, mingled occasionally with the stern voice of the weather-beaten sentinel, as he slowly paced his solitary round or perchance the gloomy screech of the lone bird of night. On the morning of the fatal day, Patrick went in an open boat to the mills at Buttermilk Falls, about two miles below, and she had prepared to visit some friends on the opposite side of the river, but would not go until his return. He was absent longer than was expected, and she repaired to the wonted place of watching, and seated herself upon a crag which shelved over the deep and dark abyss beneath. Night came on, and the faithful creature probably overcome by fatigue and anxiety, dropped asleep, fell, and was dashed in pieces. In the morning her shawl was found upon the rock, and her lifeless body among the fallen fragments, 170 feet below!

From the American Farmer.

We are indebted to Mr. Thomas Wright, of England, for a copy of "The Graziers' Ready Reckoner," and we have his assurance that the most confident reliance may be placed in its accuracy; he told us that he would not care to purchase, or sell, extensively by this guide, which has passed through three English editions, and has in that country gone into very general use. The author of the tables, gives the required weight of animals in stones, and we have converted these for the use of our subscribers, into pounds.

The Graziers' Ready Reckoner, or, a useful guide for buying and selling Cattle, being a complete set of TABLES, distinctly pointing out the Weight of Black Cattle, Sheep, or Swine, from forty two, to eighteen hundred and twenty, by measurement; together with directions, showing the particular parts where the Cattle are to be measured. By GEORGE RENTON, Berwickshire Farmer. The third edition. Berwick: price 2s. 6d. sterling.

PREFACE.

Having been often solicited to publish the following TABLES of this READY RECKONER, I am now prevailed on to do so. I by no means take the praise of them as the inventor; but have undergone a laborious task in making out the calculations, which may be of use to the public. For frequently the Buyer and Seller are at a loss even in concluding a bargain, by not being judges of the weight of the article they are treating about.

I have begun with the Calculations at three stones,* which may be as low as is necessary for those who have a swine or calf to sell; and who by no means have had such practical experience as to be judges by the eye. It may likewise be of service to those who have a beast above the common weight of cattle; they may obtain a knowledge of his value, almost to a nicety, by taking the following dimension, and considering the value per stone, sinking offals.

Take a string, put it round the beast, standing square, just behind the shoulder blade, measure on a foot rule the feet and inches he is in circumference, this is called the girth; then with the string measure from that bone the tail which plumbs the line with the hind part of the buttock, direct the line along the back to the fore part of the shoulder blade, take the dimensions on the foot rule as before, which is length, opposite these figures stand the pounds.

The girth and length of Black Cattle, Sheep, Calves or Swine being exactly taken, according to the directions given above, and wrought by decimals, would occasion a multiplicity of figures, which would be very troublesome in comparison of the following Tables, which will answer exactly to the fore quarters of any of the forementioned cattle, sinking the offal.

To bring these useful Tables into as small a compass as possible, I have not taken notice of the half inches, which confines them to the one-fourth of the figures. But to bring them to that point, when a beast measures half an inch, either in girth or length, it is only taking the difference of the leading figures. For instance, a beast measures in girth 6 feet 2 1-2 inches, length 5 feet 4 inches, the weight of

6 feet 3 inch. 697

6 " 2 " 678

Difference

19

* Of fourteen pounds each

Take the half of 19 which is 9 1/2 added to 678 and it will make 687 1/2.

To render the following small treatise as generally useful as I can, and to prevent the possibility of making any mistakes in taking the dimensions of the Cattle in improper places, I have engaged an ingenious engraver to represent the figure of an Ox, pointing out the particular places where the dimensions must be taken, in order to ascertain their weight, and I flatter myself it will be a very useful addition.

706 lbs.

To a generous public I now commit it, and hope, that, however it may succeed, the goodness of my intention will be a sufficient justification of my conduct.

GEORGE RENTON.

FOR THE NEW ENGLAND FARMER.

Thomas G. Fessenden, Esq.

DEAR SIR—In the last New England Farmer, (No. 3) I observed a communication from Professor Dana, on the subject of the correspondence between Gov. Wolcott and myself, published in the preceding number. That it should meet his approbation is to me highly flattering; but I am constrained to express my regret that he should have given to a part of it, at least, so hasty a perusal as to imbibe erroneous impressions.

The Professor seems to direct his attention chiefly to the *bleaching* process. The great object of inquiry was a *cheap* solvent, that would, without *fixing* the color, "extract the glutinous matter and weaken the woody fibre," and so simple in its application as to be conveniently used by "operative farmers." It was remarked, however, that *bleaching* might follow in a considerable degree, but it was not necessary to combine it with the object in view; as I trust it will appear that among the *desiderata* for the extension of the *linen* manufacture, the *bleaching*, a process formerly very tedious and expensive, is so completely attained as to leave but little room for further improvement. And it should be considered that the bulk, and probably the most profitable, of our linen manufactures for a number of years, or till the raw material is produced in much greater abundance, will require *no bleaching*; for instance, all the different qualities of *sail cloth* and the immense supply of *cotton bagging* for our Southern brethren.

It is gratifying that the Professor is of the opinion that "*Steam* may be employed with decided advantage for separating the glutinous matter from flax;" but my suggestions did not "forbid its application when generated from *alkaline solutions*;" on the contrary, it was stated that steam from such solutions was supposed *not* to effect the decomposition of the *cellular oil*; and I felt justified in this remark, from having observed at the *Paterson manufactory*, that the *yarns*, of which the *sail cloth* is made for the *Navy*, were submitted to the action of *steam* from an *alkaline ley*; and, in the Essay referred to in the correspondence, it was stated that "the Navy-board expressly forbid *boiling* them in such ley," and that "it was from this precaution their canvass had the pliable, oily feeling, which so much recommended it." The idea of preparing *flax* by *steam* which I suggested in the Essay, first occurred to me, two

years ago, when witnessing the process of *steaming* those yarns.

My suggestion of *simple muriate of lime* was foreign to the purpose of *bleaching*; though *lime*, when combined with *alkali*, is a powerful agent in that process; but unless used with great caution destructive to the material. Indeed it is evident, that the use of *lime* in combination with *any* substances, that may be applied to flax, should be critically graduated; and great circumspection on this point cannot be too strongly inculcated.

I remain very truly yours,

S. W. POMEROY.

Brighton, 25th Sept. 1822.

NEW ENGLAND FARMER.

BOSTON:—SATURDAY, SEPT. 23, 1822.

We have republished, in this day's paper, the *Graziers' Ready Reckoner*, which we copied from a late number of the Baltimore American Farmer. It is not in our power to vouch for its accuracy, although we have no doubt but it is useful when its calculations are applied to the breeds of cattle, &c. for which they were intended. Whether similar admeasurements, and corresponding results would help us yankees in *guessing* the weight of live stock of our common breeds is more than we are able to say. The Table, at any rate, will prove useful if it turns the attention of *Graziers* and *Butchers* to the subject; and may at least furnish hints for the construction of similar tables, adapted to the weight and corresponding dimensions of our common American animals.

We have received a communication on the subject of *CIDER*, which we think well and judiciously written. It shall appear in our next.

WORCESTER CATTLE SHOW.

The Cattle Show, Exhibition of Manufactures, and Ploughing Match, which was holden at Worcester, on the 25th inst. deserves to be spoken of in terms of no ordinary eulogy. The weather was fine, the concourse numerous and respectable, and many of our first citizens, by their presence, and the apparent zeal and animation with which they entered into the spirit of the day, evinced that they were impressed with the importance of those pursuits which this Farmers' and Manufacturers' anniversary was intended to encourage. Every thing conspired to evince that the mental and physical energies of the country were flowing in the right channel, and by the blessing of Heaven could not fail to eventuate in the full tide of national and individual prosperity. The zeal and emulation exhibited by the competitors at the Ploughing Match kept expectation (together with the other spectators) on tiptoe during the trial. The rivals in the Chariot Races of the Olympic Games could scarcely have contended with more energy and earnestness, nor could the *lookers-on* have shown more interest in their contests. The Sacred and Literary exercises of the day, the toasts, which were the *cap sheaves* of the festivities, the Oratorio of Sacred Music, which seemed to solemnize the amusements, and consecrate the business of the anniversary, were highly appropriate and gratifying. The whole proceedings were such as to awaken and excite those faculties which at once exhilarate and exalt human nature, and by being depicted in a great multitude of "happy human faces," afford an exhibition not less pleasing to the man of "good feelings,"

than the finest specimens of art, or the most perfect productions of nature.

As we propose hereafter to give a particular and official account of the proceedings of the day, we close for the present with these general observations.

A late arrival at New York from London, brings English papers to the 6th of August. They contain little interesting matter. The King is about to visit Scotland, and great preparations are making to give him a splendid reception. Scotch songs overflowing with loyalty, and imbued with the genuine quintessence of poetry, will be poured out in profusion. Sir Walter Scott, it is said, is about to levy a contribution on the muses, and decorate his Majesty's temples with garlands picked from the peak of Parnassus.

Yellow Fever at New Orleans.—A letter from New Orleans, to the editors of the Portsmouth Gazette, dated August 23, says, "The yellow fever has commenced its dreadful ravages in this ill-fated city, and as is usual, principally confined to northern constitutions. It will probably continue till the cold weather puts a stop to its career."

An invention has just been brought to perfection, in England, for the cutting, spreading and twisting of the wicks of candles, by which piece of machinery a single person can cut, spread and twist five rods in one minute, by which more than one half of the manual labor in the making of candles is saved.

A premium of a silver cup, of the value of \$12, is offered by the Bourbon Agricultural Society, in Kentucky, for the best sample of *whiskey*, in a quantity not less than one barrel.

We have had frequent occasions to mention the extraordinary growth of Apples the present season; but the following exceeds any we have yet heard of. A gentleman of Marblehead informs us, that he saw an Apple weighed on Tuesday last, which grew in a garden in that town, and the weight of which proved to be *twenty-three ounces*; and three apples (of which the above was one) weighed together three pounds and three quarters. —*Salem Gazette*.

It is said that the springs in the county of Plymouth have never been so low, as at present, within the memory of man.

Rye Coffee.—It is stated that Philadelphia furnishes Boston with about 5000 barrels of rye coffee in a year.

The Duel.—We do not believe a single instance ever occurred, so calculated to check the ridiculous and absurd practice of settling principles of honor by skill in sharp shooting, or questions of character at the muzzle of a pistol, as the controversy between Colonel Cumming and Mr. McDuffie. In addition to the statements previously furnished, the New York Mercantile Advertiser, on the authority of letters received there from Augusta, says, at the time of the arrest, a *large military force was on the spot*! What perfect *Orlando Furiosos* these combatants must be. Some people could be kept apart by two platoons or such a matter of infantry, but these champions required a *large military force* to effect the purpose.—The following article from the *Morning Post*, we really think too severe; but these champions must expect a few rubs, as an offset for the great anxiety and trepidation they have caused among the public:

RETURN of the killed, wounded and missing in the late wonderful Duel between Mr. McDuffie and Col. Cumming.

Killed—none,
Wounded, in the back—one,
Missing, at roll call—none,
Shook hands—two,
Seconds—safe,

Horses and negro coachmen—alarmed,

The Public—very much amused by the performers, who appear to have paid great attention to stage effect. Further particulars in the bills of the play.—*Balt. Pat.*

From Mrs. Colvin's Weekly Messenger.

THE FOX AND ANT.

BY JOHN E. C. '66. 1868.

An Ant would have her picture drawn,
By Fox, the STUART of the lawn;
Whose matchless sketches bold and true,
Are all as like as they can stare.
This tiny ant in Reynard's hole
Said, "Though admir'd by every soul
Still I am mock'd as coquet-lamb,
And would be painted as I am?"
Good, said the Fox, that's my affair—
Pray, Ma'am, be seated in the chair.
She squats. Conceit began to fret,
(The Ant was a complete coquette.)
And roll'd her eyes and toss'd her head,
And bit her lips to make 'em red;
For'd many a trait from love to spite,
Killing to look with all its might.
Fox, with the pallet in his paw,
Took snuff, and then began to draw,
Glanc'd o'er her face; found little in it—
And did her likeness in a minute.
Ant rose and look'd—"Ye powers," says she,
'Is this poor little image me?'
'Me? me not bigger than your thumb?'
'The daub is not like me a crumb.'
'No, by the powers that rule the ball,
'It is at least two thirds too small!'
Fox, who descried her shoals and shelves
Replied, 'Miss Ant, few know themselves;
'Small folks, by great conceit puff'd out,
'Are not one grain more great for that!'

MEDICINAL.

We are aware that medical prescriptions, conveyed through the medium of a newspaper, carry with them no great force of authority.—It has not unfrequently happened, however, that they have been productive of good. The greatest discoveries in philosophy have been the results of reflection, operating upon casual incidents. Valuable principles have been developed in the healing, as well as in other arts, by fortuitous circumstances; and perhaps the following items, which we have selected from English papers, may have the effect to rescue some one of the human family from the evil it proposes to remedy. Should its application in a single instance be salutary, the labor bestowed will not have been regretted.—*American.*

Croup.—Dr. Reddelin, of Weismar, has communicated to the Royal Society at Gottingen, the following successful treatment of Croup, after the usual remedies had been tried without effect:—The patient was a female aged 19, who, on the third day after being seized with the Croup, was unable to swallow, had begun to rattle in the throat, and seemed approaching rapidly to dissolution. Dr. Reddelin insinuated, by means of a quill, a mixture of Spanish snuff and marrocco into her nostrils; and after repeating this mixture a second time, it excited sneezing and vomiting; this occasioned the discharge of two long membranous cylinders from the trachea (wind-pipe) upon which the rattling immediately ceased, and the patient was rescued from instantaneous suffocation. One of the tubes, when split open, measured nine French lines in breadth; they were quite white, and bore a strong extension without injury to their fibrous texture.

It is said to be a specific for the rheumatism, to apply a cabbage-leaf to the part affected.—Choose a perfect leaf, cut off the protuberant stalk on the back, and place it on the part with a bandage of flannel on going to bed. It will produce a local perspiration, and in two or three repetitions a cure will be effected.

A writer says, "tobacco exhausts those juices so essentially necessary to further digestion; it creates thirst and nausea; it destroys appetite; the complexion becomes cadaverous; finally, the chewer and smoker becomes a poor miserable emaciated atrophic walking skeleton, smoking away his few remaining ideas, and spitting up his lungs, until death releases him from all his sufferings." The truth, we believe, is, that to many constitutions tobacco is hurtful—to others, innocent; and the true course is for those who find it injurious, to abstain from its use. That it is pernicious to young people generally is past a doubt, and therefore its use by them ought to be forbidden or discouraged.

Great Establishment.—There is an extensive Manufacturing Establishment at Dover, N. H. The capital is \$500,000; a great part of the shares, we believe, are owned in this city (Boston.) The proprietors have a Cotton Manufactory, which carries 2500 spindles, employs 36 looms, 120 hands, and at which 10,000 yards of sheeting and shirting are manufactured and bleached per week. During the last season, the company erected a building of 80 by 54 feet, 4 stories, embracing a rolling and slitting mill, nail factory and machine. The basement and second stories are devoted to the rolling and slitting mill—the construction of the rolling mill is on a new principle, having but one water wheel placed at the side of the platform. The third story is used as the nail factory, and from 6 to 700 tons of iron per year, are cut into nails in this factory. The 4th story is occupied as a machine shop, in which 40 hands are employed, in making the various kinds of machinery for a new cotton manufactory, now erecting on the same falls, which is to be 154 by 43 feet, and will carry 4000 spindles, and employ from 150 to 200 hands, and probably produce 20,000 yards of cloth per week.—This, with other improvements going on at Dover, will prove of lasting advantage to the town, which is destined to become the Manchester of New-Hampshire.—*Gazette.*

Baltimore Manufactories.—The Federal Republican says, there are 13 cotton mills in that vicinity, which drive at least 32,830 spindles—2 woollen mills—1 copper rolling mill, which is the only one of note in the United States—3 extensive rolling-mills, which manufacture annually at least 1500 tons of iron into rods, hoops, bolt and sheet iron—besides at least 30 of the best and most improved merchant-mills within the limits and environs of the city, that manufacture about 300,000 barrels of flour annually.

From the New York American.

A method of working pumps, by means of a *capstan*, has lately been invented by P. T. Voorhees, first Lieut. of the U. S. ship Washington. The machinery is simple, not expensive, and so constructed as to admit the common way of

working the pumps with less fatigue than is usual. This is a highly important discovery, and cannot fail to induce every ship owner to avail himself of the plan for the use of his ship. Insurance offices would find it to be their interest, and would do an act of humanity, were they to insist, as one of the conditions to insurance, that this highly improved plan should be adopted by every ship over which they might have any control. It is understood that Lieut. Voorhees intends to present his invention to the different foreign governments through the medium of their Ambassadors at Washington.

Piety communicates a divine lustre to the female mind—wit and beauty, like the flower of the field, may flourish for a season; but let it be remembered, that like the fragrant blossoms that bloom in the air, these gifts are frail and fading. Age will nip the bloom of beauty; sickness and sorrow will stop the current of wit and humor; and in that gloomy time which is appointed for all, piety will support the drooping soul, like a refreshing dew upon the parched earth.

I am an admirer of simplicity; but I never feel a greater impulse to pay homage at its shrine, than when it sheds its soft lustre on the female sex. I am pleased when I behold woman in such lights and shades of soul, temper and disposition, as nature has originally formed her in. Were I to select a fair

"For solid comfort and connubial love," it should be her, who, reared in seclusion, was the genuine child of simplicity—whose spotless mind has never received an unfavorable impression from the follies of a fashionable world.

Sorrow and calamity are the surest test of religious principle; and religious principle rises to moral sublimity when it teaches the suffering individual to breathe its glorious spirit through its own hallowed medium.

Intellectual talents are the noblest gift of the Almighty, but they involve their possessor in high and solemn responsibility. Prostituted genius is the nearest resemblance of the spirit of evil. It looks like Satan clothed in the garb of an angel of light.

The virtues, like the vices, are so fond of one another that they are seldom or ever found separate; and if a virtue or two be sometime found crowded in amongst many vices, they are only like sprigs of geranium set without root in a garden, which, before they have time to take root, are thrown down by the first shower or gust of wind, and wither away directly.

Lost money may be found again; but a lost character is seldom recovered.

Sir Nicholas Bacon, a judge in the time of Queen Elizabeth, was once, while on the bench, importuned by a criminal to spare his life on account of his kindred. "How so?" asked the Judge. "Because my name is Hog and you are Bacon, and hog and bacon are so near alike that they cannot be separated." "Aye," said the Judge, "but you and I cannot be kindred except you be hanged; for hog is not bacon until it is well hanged."—*Bacon's Essays.*

NEW ENGLAND FARMER.

Vol. I.

BOSTON, SATURDAY, OCTOBER 5, 1822.

No. 10.

HOPS.

We have been frequently requested to give, in the *New England Farmer*, a statement of the most approved method of cultivating Hops. We accordingly copy the following from Messrs. Wells & Lilly's edition of Deane's *Georgical Dictionary*. If any of our readers are in possession of any more improved mode of producing that article, we should be very glad to receive an account of it for publication.

HOP, *Humulus*, a narcotic plant of the reptile kind, the flower of which is an ingredient in beer, ale, &c. As I have not had much experience in hops, I shall give an account of the management of them, chiefly abstracted from the *Complete Farmer*, and abridged.

A rich, deep, mellow, dry soil, rather inclining to sand than clay, is best adapted to the cultivation of hops. A black garden mould is excellent.

The ground should be ploughed very deep, or dug with a spade, reduced to a fine mould by repeated ploughing and harrowing, and laid even.

When the ground is in proper readiness for planting, let a line be stretched on a straight side of a field, with knots or rags in it, as far asunder as you design your hills shall be; and stick in the ground a sharp pointed stick at every knot, as marks for the places where the hills are to be made. Remove the line to such a distance as to make the hills equidistant both ways; and so on through the whole ground.

The distance of the hill should be regulated by the strength of the soil. But in every case they should be far enough asunder to admit the hoe plough at all times. If the soil be dry and shallow, six or seven feet will be a convenient distance: But if it be rich, moist, and apt to rear large hops, it may be right to allow eight or nine feet.

The time to plant hops is when they begin to shoot in the spring. The sets are cuttings from the roots, or branches which grow from the main root. They should be from five to seven inches long, with three or more joints or buds on each, all the old and hollow part being cut off. Make holes twelve or sixteen inches wide, and of a depth proportioned to the nature of the ground. If shallow, with hard clay or gravel under, dig not into it, lest you make a basin to retain water; but raise a small hill of good mould. If there is a good depth of rich mellow mould, dig the hole a foot and a half, or two feet deep; the hops will thrive the better.

When all things are ready for planting, fill up the holes with the mould before thrown out, if it be good; but if the same earth be not rich enough, make use of fine fresh mould, or of a compost provided for the purpose, a peck in each hill, but no dung on any account.

Then with a setting stick make five or six holes, one in the middle perpendicular, and the rest round it sloping, and meeting at the top near the centre. Put in the sets so that they may stand even with the surface, press the mould close to them, and cover them with fine mould two or three inches thick. A stick

should be placed on each side of the hill to secure it.

The ground being thus planted, all that is to be done in the following summer is to keep the hills and alleys clear of weeds by frequent hoeings, to dig the ground in May, and carry off the stones raised by digging; to raise a small hill about the plants, and throw some mould on the roots, and in May or June to twist all the vines and branches together in a loose knot, and lay them thus twisted on the top of the hill.

Early in the following spring, when the weather is fine, open the hills, and cut off the shoots of the first year, within an inch of the stock, together with the younger suckers that have sprung from the sets, and cover the stock with fine earth.

In the third and following years, when you dig your hop ground, let the earth be taken away with a spade or hoe, round about the hills, very near them, that you may more conveniently come at the stock, to cut it. Then in fair weather, if your hops be weak, begin to dress them: But if strong, do it later; for dressing late restrains their too early springing, which hurts the hop.

After dressing in the second year, the next thing is to pole them.—Poles ten or twelve feet long will do then; but in the third year, when they come to their full bearing state, they will require poles of full size: This, if the ground be rich, and the hop vigorous, will be from sixteen to twenty feet; or there will be danger of losing great part of the crop.

The hop will soon run itself out of heart, if it be over poled. Neither can a good crop be expected from over poled ground: because the branches which bear the hops grow very little, till the buds have overreached the poles, which they cannot do when the pole is long. Two small poles are sufficient for a hill in a young ground.

A hop garden, Mr. Young says, will last almost forever, by renewing the hills that fail to the amount of about a score annually; but it is reckoned better to grub up and new plant it every 20 or 25 years.

In forward years hops are ripe at the beginning of September.—When they begin to change colour, or are easily pulled to pieces; when they emit a fragrant smell, and when their seed-begins to look brown and grow hard, you may conclude that they are ripe. Then pick them, with all expedition; for a storm of wind will do them great mischief at this time.

When the poles are drawn up in order to be picked, the vines around should be cut asunder at the height of three or four feet from the ground: For cutting them lower, especially while the hops are green, would occasion so great a flow of sap, as would weaken the root.

It has been remarked by one who had much experience, that hops which are late picked bear more plentifully the following year than such as are picked early: For which reason he recommends late picking. But the hops which are picked early look better, and are undoubtedly stronger.

The best way of drying hops is on kilns.

Four pounds of undried hops, will make one pound after they are dried.

Before hops are bagged, they should be laid in a heap, that they may sweat and grow tough: And if they are covered for a while with blankets, they will be the better. The bags are coarse linen cloth. They are commonly about eleven feet long, and near two yards and a half in circumference, and contain about 250 weight of hops. The small bags, called pockets, contain about half as much.

The manner of bagging is thus. Make a round or square hole about 20 or 30 inches over, in the floor of the chamber where the hops are laid in heaps after sweating. Tie with a piece of pack thread, a handful of hops in each lower corner of the bag, to serve as handles for the more easy lifting or removing, the bag; and fasten the mouth of the bag to a frame, or hoop, somewhat larger than the hole, that the hoop may rest on its edges. The upper part thus fixed, the rest of the bag hangs down through the hole, but not so far as to touch the lower floor. Then throw into it a bushel or two of hops, and let a man go into the bag, and tread the hops down till they lie close; then throw in more and tread; and so on till the bag is full. Loose it from the hoop, and sew up the mouth as close as possible, tying hops in the upper, as was done in the lower corners. The harder the hops are pressed, and the closer and thicker the bag is, the longer and better the hops will keep.

A small manuring of hop ground every second year is sufficient.—Dung was formerly more in use than at present, experience having shewn that lime, sea sand, marle, ashes, &c. answer the end better, and last longer. But hog dung prevents mildew from taking hops.

Each pole, according to Dr. Hales, has three vines, which makes six vines to a hill. All the sprouts above this number, should be broken off in the spring.

From the *American Farmer*.

Prince George's County, Sept. 20th, 1822.

DEAR SIR—I do not recollect to have seen in your paper, a cure for the disease to which dogs are subject, commonly called the distemper.

Altho' I am a professed enemy to *curs*, biped and quadruped, yet I confess I feel great respect for some dogs, and take pleasure in relieving them from a malady which let alone, or injudiciously treated, becomes fatal to thousands.

The cure is simple and certain. To a dog eight months old, give 4 grains of Turbeth's mineral in gruel or any thing else in which it will mix. Keep him from cold water 24 hours, then give 4 grains of crocus metallorum, and turn him out. I have never known this remedy to fail.

A Cucumber was raised in a garden in Portland, by Mr. John Young, which measured twenty inches in circumference, and weighed seven pounds and two ounces.—*Portland Gaz.*

From the Massachusetts Spy of October 2.

CATTLE SHOW, &c.

On Wednesday last, the Worcester County Agricultural Society held their Fourth Anniversary Cattle Show, Ploughing Match, and Exhibition of Manufactures. Again we congratulate the Members of the Society, and the Farmers of the County of Worcester, on the honorable result of their continued exertions. The spirit which has been manifested on former occasions appears to be undiminished, and the effects which it has already produced in every branch of agricultural improvement, surpass the anticipations of the most sanguine. The present Exhibition has not detracted from the reputation of our County; and was highly gratifying to the distinguished agriculturists who visited us upon this occasion.

The *Examination of Manufactures* took place on the day preceding the Public Exhibition.—They occupied a spacious and convenient room, kindly offered to the use of the Society, by S. Brazier, Esq. We regret to say that the show of Manufactures was far inferior to what it has hitherto been. Though most of the specimens were excellent in quality, they were deplorably deficient in variety and quantity. In many articles there was no competition, and indeed no specimen offered; and of course, the proposed premiums were saved to the funds of the Society! There is no part of the Commonwealth able to make so fine a display of Manufactures as the County of Worcester. There is no other County which contains so many great manufacturing establishments; and yet every other County, in this respect, exceeds us in its public Exhibitions. It is not our present purpose to inquire into the cause of this mortifying circumstance; but whatever it may be, if our manufacturing brethren despise the aid of the Society, and are regardless of the honor of the County, there is but one course to be pursued. The Society must abandon all hopes of conciliating their favor, and must divert into another channel the limited means of encouragement which it is in their power to bestow. In other branches of domestic industry, competitors will be found who are not too proud to receive our premiums. In some articles of domestic manufacture, there was on this occasion a very fine display. The dairies supplied numerous and excellent specimens of Butter and Cheese.

The day of the Exhibition was a pleasant one, and the concourse of people as great as on any former occasion. The arrangements for the accommodation of Stock of all kinds was ample. Eighty-eight pens were erected, and nearly all of them were filled with fine animals. The show of Stock we thought uncommonly good. The young animals particularly were of high promise, and the descendants of the famous bull "*Denton*," appeared in increased numbers, and with the most decided marks of excellence. Beside the animals in the pens, there was a handsome number of working cattle entered for premium; and great eclat was given to the occasion by the exhibition of two long lines or teams of strong and beautiful working oxen; one from Worcester, of one hundred and twenty yokes; and another from Sutton, of about fifty yokes. The farmers of these towns deserve much credit for adding so much to the interest of the spectacle. Our Sutton friends in

particular will accept our thanks for the pains they must have taken in sending their cattle to Worcester. Altho' their numbers were smaller than those of the other line, yet the exhibition was considered as equally honorable to them, taking into consideration the distance from which they came. We all know that they can increase the number of their team, whenever occasion may require.

By the book of the Assistant Recording Secretary, Mr. Wm. D. Wheeler, it appears that the number of Animals regularly entered (exclusive of the above-mentioned teams) was two hundred and nineteen—153 of which were Neat Cattle, and 66 Sheep and Swine. It will be observed that the number of Neat Cattle considerably exceeds that of last year, whilst the number of Sheep and Swine is much smaller.

There was great punctuality in executing the previous arrangements, otherwise it would have been impossible to complete the arduous duties of the day. Every thing was conducted with perfect regularity, and there was no hurry or confusion. Indeed decency and order marked all the proceedings of the day. We mean no invidious comparison when we say that in no section of the country would such a great assemblage of people have demeaned themselves with greater propriety and decorum.

The performances of the day commenced with the *Ploughing Match*—The ground selected was a green sward, which, for more than twelve years, had been improved for mowing. The soil was a mixture of clay and gravelly loam, and owing to the unusual dryness of the season had become very hard and compact. The land had been laid out into lots of an eighth of an acre each. Ten persons drew for lots, and they started together in the match, a few minutes after 9 o'clock. A subsequent sketch of the Committee's report will show in what manner the work was performed.

At 11 o'clock, the Society moved in procession to the South Meeting-House. The services were introduced by a pertinent prayer from the Rev. Joseph Gaffie. An Address was pronounced by NATHANIEL P. DENNY, Esq. of Leicester, one of the Trustees of the Society. It was an earnest appeal to all descriptions of our fellow-citizens to discard prejudices of every kind, whether sectional, professional or traditional; and to unite, as those having one common interest in promoting the great objects for which Agricultural Societies have been instituted. The Orator gave an ingenious exposition of the mutual dependence of Agriculture and Manufactures, and the importance of affording ample encouragement to the latter, in order fully to develop and call into action the resources of the former. To all his sentiments upon the subject of affording extra encouragement to Manufactures, probably many of his audience did not accede; but we believe all were satisfied that the general tendency of his Address was useful to every class of the community. The performances concluded by an Anthem, sung with taste, spirit, and effect, by several amateurs of Boston and Worcester. After the conclusion of the services, the names of the various Committees were announced; and the procession being formed in the same order in which it entered the house, made a circuit of the pens to view the animals which they enclosed, and was dismissed in the area between the pens. The Committees then

proceeded to discharge their respective duties. At two o'clock, a procession was formed for dinner, which was handsomely provided by Messrs. Howe & White, at their Hotel. Hon. Daniel Waldo, presided at the table. After dinner the following toasts were announced.

1. Agriculture—The mistress of all arts. Her enviable lot is to find her sisters multiplied, and her charms increased by age.
2. American Manufactures.—Skill and industry have become an honorable and an ample substitute for legislative protection.
3. The Massachusetts Agricultural Society.—The soul which animated "the Heart," and is infusing life into the extremities of the Commonwealth.
4. Our Naval Heroes.—When they plough, we reap a harvest!
5. Presidential Competitors.—As their teams have not been duly entered, and have started without signal, the Judges are not pledged to award premiums.
6. The Chain of Union.—Tight, without galling.
7. The Yoke Matrimonial.—To keep both ends even, let neither side have the advantage.
8. The Spindle.—By one revolution our independence was achieved—by millions it is perpetuated.
9. Cattle Shows—and all other Shows but the Lawyer's "chase in action."
10. Those who work and those who play.—May the former have employment, and the latter means to pay for it.

After the third Toast, the Hon. Mr. WELLES, one of the Trustees of the Massachusetts Agricultural Society, rose and returned his thanks for the handsome manner in which the parent Society had been noticed, congratulated the members of the Worcester County Society upon the honorable result of their exertions, and expressed his hearty wishes for their future prosperity. He then proposed the following sentiment:—

The Worcester Agricultural Society.—May their success be commensurate with their zeal, intelligence and patriotism.

The following Toast was given by the Hon. Mr. LLOYD.

The Yeomanry of Massachusetts.—Institutions, intelligent and independent—natives of the soil—a stock of the first class, and not to be improved by any foreign crosses.

At 5 o'clock the Trustees assembled in the Meeting House, and the several Committees made their Reports, of which only a summary sketch can now be given.

The Committee on *Mar Stock* consisted of Hon. Levi Lincoln, of Worcester, Chairman; Mr. Paul Dudley, of Douglas, Mr. James Adams, of Barre, Hon. Jonas Sibley, of Sutton, and Mr. Levi Bartlett, of Rutland. This Committee, as usual, made a very long and interesting Report.

The Committee expressed themselves in terms of admiration at the excellence of most of the Stock exhibited. They remarked with what high satisfaction they had witnessed the improvements taking place in those properties which render Stock valuable. The Chairman again congratulated his fellow citizens upon the introduction of the Durham improved short-horned breed into our country—upon the preference which is now given to this breed by many of our best farmers—and upon the progress it is making, in spite of prejudice, in the public estimation. Many other judicious and well-timed remarks were made by the Committee, which we will not anticipate, because it is proposed to lay the whole of their report before the public in a week or two; and we hope that not a farmer in the County will neglect to read it. After observing upon the difficulties

culty of discrimination where merit was so nearly equal, and regretting that they could not bestow more reward where so much was deserved, the Committee recommended the following premiums:—

To Jason Waters, of Sutton, for the best Bull,	\$15
To Messrs. Ward & Rice, of Worcester, for the next best,	10
To Reuben Nowhall, of Spencer, for the best Bull Calf,	6
To John Sherman, of Sutton, for the next best,	4
To Horace Warren, of New Braintree, for the best Milch Cow,	15
To Elisha Matthews, of do. for the next best,	10
To John Ayres, of Oakham, for the next best,	5
To Stephen Williams, of Northboro', for the best Heifer,	6
To Asa Rice, of Worcester, for the next best,	5
To Amos Sheldon, Jr. of Fitchburg, for the best Heifer Calf,	5
To John Davis, of Worcester, for the next best,	4
To Thomas W. Ward, of Shrewsbury, for the best four year old Steers,	10
To Simon Phelps, of Sutton, for the best 3 year old Steers,	5
To Nathl. Gates, of Worcester, for the next best,	5
To Luther Whiting, of Sutton, for the best 2 year old Steers,	7
To Luke Baker, of Rutland, for the best yearling Steers,	5
To James Black, of Barre, for the next best,	3
To Lewis Barnard, of Worcester, for the best Fat Ox,	15
To Asa Rice, Jr. of Shrewsbury, for the next best,	10

The Committee particularly mentioned the following Animals as worthy of notice, viz:—The Bulls of Mr. Horace Warren, of Grafton; of Mr. Hale, of Royalston; Mr. Leland, of Grafton; Mr. Sheldon, of Fitchburg; and Mr. Miles, of Westminster; the Bull Calf of Doct. Ball, of Northborough; the Cows of Mr. Boylston, of Princeton, and Col. Watson of the same town; the Heifers of Theophilus Wheeler, Esq. of Worcester, Mr. Peters, and Mr. King's, of Rutland; the Heifer Calf of Mr. Elisha Flagg, of Worcester; the Steers of Messrs. A. & J. Chase, of Sutton; those of Mr. Isaac Dodge, Jr. of the same place; those of the Rev. Mr. Daggett, of Mendon, (unfortunately not entered in season for premium;) those of Mr. Cyrus Lovell, of Worcester; those of Mr. Elisha Sumner, of Rutland; of Mr. Cummings, of Sutton; of Mr. Hathaway, of Grafton; of Mr. Heywood, of Millbury; of Maj. Tenny, of Sutton; and those of Mr. Joel Wesson, of Millbury; the Fat Oxen of Col. Wyman, of Shrewsbury; and those of Mr. Benjamin Woodbury, of Sutton. Among the descendants of Denton, besides those above mentioned, the Committee also mentioned in terms of high praise, the Bull Calf of Col. Watson, of Princeton; the Bull and Bull Calf of Lovett Peters, Esq. of Westborough; the Bull Calf of Maj. Newton; the Bull Calves of Maj. Davis; the Bull Calf of Hon. Oliver Fiske, and that of Mr. Benjamin Butman; and the Heifers, Bull and Heifer Calves of Maj. Lincoln.

The Committee on *Working Oxen* consisted of Seth Lee, Esq. of Barre, Chairman; Col. Wm. Foster, of Sturbridge, Joseph Estabrook, Esq. of Royalston, Mr. John Batcheller, of Grafton, and Col. William Eager, of Northborough. The Chairman of this Committee had time only to make a summary report. The performances of all the competitors were well spoken of.—The Committee recommended the following premiums:—

To Luther Whiting, of Sutton, the 1st premium,	\$15
To Seth Wyman, of Shrewsbury, 2d premium,	12

To Jonas L. Sibley, of Sutton, 3d premium, 10
To Nathaniel Gates, of Worcester, 4th premium, 5
The Committee also particularly commended the Working Cattle of Mr. Joseph Dudley, and Mr. Peter Darling, of Sutton.

The Committee on *Merino, Mixed, and Native Sheep*, consisted of Hon. Aaron T. 's, of Dudley, Chairman; Capt. Cyrus Gale, of Northborough, and Mr. Willard Rice, of Spencer. The Chairman of this Committee made some pertinent and forcible observations upon the great deficiency which was apparent in this kind of Stock, than which none, under proper management, can be more profitable to the farmer. He recapitulated all the advantages which might be derived from the encouragement of an improved breed of sheep, and the particular advantages which the County of Worcester enjoys in this respect. And he greatly lamented that with such means as we possess to do ourselves and our County justice, there should be such a meagre exhibition. His Report will hereafter be published in detail, and we hope it will be generally read and as generally profited by. The Committee recommended the following premiums:—

To William Lincoln, of Worcester, for the best Merino Ewes,	\$10
To John Davis, of Worcester, for the second best	5
To Levi Lincoln, of Worcester, for the best Merino Wether,	4
To Ezra Bigelow, of West-Boylston, for the best lot of Mixed Merino Ewes,	5

There was but one Merino and one Native Ram entered. The Merino had before received a first premium, and was not considered as entitled to another. The Native Ram was not judged worthy of a premium.

The Committee on *Swine* consisted of Lovett Peters, Esq. of Westborough, Chairman; Col. Seth Wyman, of Shrewsbury, and Mr. Rufus Porter, of Worcester. They recommended the following premiums:—

To John Gleason, jun. of Worcester, for the best Boar,	\$10
To Asa Rice, of Worcester, for the Best Weaned Pig,	4
To Joel Gates, of Worcester, for the best Breeding Sow,	3

The Committee regretted that the competition in this valuable article of Stock was so limited. They mentioned with approbation a Boar of Maj. Simon Burt, and one of Mr. Simon Gates—also the Pigs of Theophilus Wheeler, Esq. and of Mr. Joel Gates.

The Committee on the *Ploughing Match* consisted of Hon. Seth Hastings, of Mendon, Chairman; Samuel Read, Esq. of Uxbridge, Moses Thomas, Esq. of Sterling, Samuel Mixter, Esq. of New-Braintree and Charles Mirick, Esq. of Princeton. The Committee congratulated the Society on the continued and increasing interest excited by the Ploughing Match, and remarked how great an object it was to give to our fields a better cultivation than formerly, at a less expense of labour, by improvements in the construction and use of the plough. The Committee reported that ten competitors had performed in their respective lots as follows:—

Lot No. 1. John Park, of Millbury, one yoke of Oxen; himself ploughman, no driver; work performed in 27 minutes 42 seconds—19 furrows—plough made by Ebenezer Learned, of Ward.	
No. 2. Jabez Brigham, of Worcester, one yoke of Oxen; ploughman, Moses Brigham, no driver; work performed in 22 minutes—20 furrows—Dutch plough with a wheel, made by E. Learned.	
No. 3. Jonas L. Sibley, of Sutton, one yoke of Oxen,	

ploughman, Daniel Edley, driver, Stephen Darling, work performed in 19 minutes, 53 seconds—18 furrows—common plough with a wheel, made by A. Chase, of Sutton.

No. 4. John Sherman, of Sutton, one yoke of Oxen; ploughman, Asa Cummings, driver, John Sherman, work performed in 13 minutes, 30 seconds—18 furrows—common plough with a wheel, made by John Hall, of Sutton.

No. 5. Moses Adams, of Sutton, two yokes of Oxen; ploughman, Owen Brown, driver, Tyler Marble; work performed in 17 minutes—16 furrows—common plough with a wheel, made by A. Chase.

No. 6. Levi Lincoln, of Worcester, two yokes of Oxen; ploughman, Philomen Wright, driver, Ardenne Ward, 2d; work performed in 20 minutes—15 furrows—Harrison's patent plough.

No. 7. Silas Dudley, of Sutton, one yoke of Oxen; himself ploughman, driver, Joseph Dudley; work performed in 20 minutes 53 seconds—19 furrows—common plough with a wheel and cutter, made by Jesse Warren, of D. dham.

No. 8. Nathaniel Gates, of Worcester, two yokes of Oxen; ploughman, Levi Gates, driver, Nathaniel Gates; work performed in 24 minutes 53 seconds—16 furrows—Wood's patent plough.

No. 9. Peter Darling, of Sutton, one yoke of Oxen; ploughman, Nathaniel Carroll, driver, Peter Darling; work performed in 30 minutes 2 seconds—19 furrows—common plough with a wheel, made by John Holman, of Ward.

No. 10. Nathaniel Brooks, 2d. of Worcester, one yoke of Oxen; ploughman, Lailly Clements, driver, Nathaniel Brooks, 2d; work performed in 23 minutes; 18 furrows—common plough, made by Mr. Emerson, of Haverhill.

The test of merit was the best work with the least expense of labor. The following premiums were recommended:

To Jonas L. Sibley, the *first premium* of Ten Dollars for the plough; Five Dollars to the ploughman; Three Dollars to the driver.

To John Sherman, the *second premium* of Eight Dollars for the plough; ploughman Four Dollars; driver Two Dollars.

To Silas Dudley, the *third premium* of Six Dollars for the plough; ploughman Three Dollars; driver One Dollar.

To Moses Adams, the *fourth premium* of Four Dollars for the plough; ploughman Two Dollars.

[The remainder of the Report will be given as soon as received.]

Accful calamity.—By a gentleman passing this place from Chenango, we learn the following melancholy circumstance, which he stated to have occurred last week in the town of Otsele, in the above county.

A large number of men were employed in raising a barn; two young men were scuffling, and the neck of one was broken in the affray; in this situation he was carried before his father, who was holding a corner post of one of the *bents*—when, (dreadful to relate,) the father, shocked at the horrid spectacle, left his hold, by which means the timbers fell and killed seven men on the spot.—*People's Friend.*

Squirrels.—These destructive animals are stated to be making great ravages among the corn in Ohio. Myriads of them were found in every direction, and it was feared many of the farmers would lose the whole of their crops. Several hunting parties had been formed, and in many instances thousands of them have been destroyed, but still their numbers did not appear to be in the least diminished. Great quantities of them were killed in fields with clubs and stones, and they were literally thronging the streets and house tops of the villages.

FOR THE NEW ENGLAND FARMER.

CIDER.

MR. EDITOR,

Cider is our natural beverage. That it is capable of surpassing the wines of other countries, is a fact frequently well attested at the tables of affluence. To facilitate its more extensive experience is the purpose of this communication.

Agriculture, of which the making of Cider is a part, is the first of sciences. Its pre-eminence entitles it to the distinction of the Divine science. But much is left to the *reason* as well as the *labor* of man to exalt it to perfection; and in this economy of Providence, who can be insensible to its benignity and condescension in making us joint laborers in the accomplishment of our enjoyments? I am persuaded that you will not think this seriousness as out of place, since, in connexion with the immediate advantage, it must have been the basis of institutions for the encouragement of agricultural pursuits. In a pecuniary view, the subject is within the demonstration of arithmetic—in years of usual abundance, it may be computed, that a million of barrels of cider are made in Massachusetts, worth, in such years, a dollar each, made in the common manner; any mode of making which, without material multiplication of expense, shall enhance this price, will add the additional value to the stock of profit; and it is not extravagant to say, that even in years of the greatest plenty, like the present, it may be so improved in quality as to be advanced to ten times its ordinary price. Nor is it the epicure alone who would willingly pay for the luxurious draught—the salubrity of a pure and palatable liquor would force parsimony itself into the *economy* of its purchase. Our autumnal complaints derive, in a great measure, their existence and aliment from the use of viscous and rapid juices. The proverb, that it is better to pay the butcher than the doctor, is much exalted in its application to the present subject—it is better to comply with the terms of nature, than to endure the penalties of their transgression. The apple tree, like the vine, is dependant on man:—through his delinquency, the yieldings of both degenerate into vinegar, but on the performance of his duty, they are exalted into wine.

A finished speculation on the making of Cider, should begin with the songs of the Mantuan bard, on

"The kinds of stock, and what those kinds will bear."

And on the methods and progress of cultivation, from the "wild disorder" of the nursery to

"The stately tree, which in autumn bends
With boding treasures."

For,

"Wouldst thou thy vats with generous wine should
froth?"

Respect thy orchards;—think not that the trees
Spontaneous will produce a wholesome draught.
The plant which shoots from seed, a cullen tree,
At leisure grows: for late posterity,
The generous flavor last."

But as these pleasing and interesting investigations are better adapted to seed-time than harvest, I will pass on to the business of the season—the *making and preserving Cider*. A clean, convenient and covered mill, is the first pre-requisite, for without such a mill, all other attentions may be frustrated. The apples should be reduced to a fine pulp. The color of the

liquor and its smoothness are both improved by laying a few hours in the trough after grinding. Lay up the pomace on the press in clean straw, without using a drop of water in any part of the process. Three or four times as much water is often used in making less than a hog-head of cider, than would be required to ruin a pipe of proof-spirit. Every mean should be adopted to retain the spirituous property of the liquor—it is its life. If a cider is wanted,

"Some strong, to cheer

The wintry revels of the laboring hind,
And tasteful some, to cool the summer hours."

the cheese may be reground, with some assistance from the well.

"Water will imbibe

The small remains of spirit, and acquire
A vinous flavor."

Press the cheese gently at first, and advance slowly to the utmost power of the screw.—Art now commences its operations against the "floating lee"—and in no stage of the business can they be more effectually interposed—in proportion to the clarification of the stum the tendency to an ensuing fermentation is moderated, and its dangerous excess arrested.

In turning up, as it is called, out of the tub, the grossest of the pomaceous mass is usually detained by a strainer of straw, coarser than "the goat's shaggy beard." In stead of such a strainer, prepare a tunnel with moveable rims, in the form of a sieve—over the bottom rim, stretch a covering of fine flannel—over the second, a covering of baize, and the uppermost overspread with drugget, with the nappy side of each pendant. These strainers will arrest on their way to the vessel, all the gross and most of the subtle impurities which tend to the agitation and vitiation of the liquor. Should the strainers choke they can be easily relieved.

We now advance to the *preservation* of the Cider, which is the principal difficulty; and after all the directions which can be given much must be supplied by discreet observation. The vinous, the acetous, and the putrefactive, are the three fermentations to which the liquor is inclined—they are, indeed, but one progressive operation, with intermediate pauses. The first is an effort to free itself from a farther association with the fruit, and to excite its own spirit, and is closed with a calmness which marks an intermission of the endeavor—an advance to the second, which converts into vinegar, is restrained only by the due ascendancy and retention in the body of the liquor of the spirituous quality excited and quickened by the first—the last is produced by an irreclaimable foulness. The intermission between the two first is short, and has been considered the critical moment for the successful interposition of art, and racking, fumigation, salt-petre and rough-alum, have been species relied upon; but more is depending on the *internal condition of the liquor*, than on these prescriptions, or on any other consideration. Ciders of a good standing, purified and protected from the internal and external occasions of its injury, by an attention which ought to be as common as washing down a hog before cutting it up, will never depreciate into sourness; nor will any application reclaim that which sunk under the pressure of its inherent impurities, or lost its virtues by the inattention of its keeper. In respect to racking, however, if it be ineffectual for the

renewal of the liquor, it is seldom attended with disadvantage, and is sometimes the best expedient for its purification.

The quality of the juice of an apple in its natural state, is the prime inquiry to guide all our decisions on the flavor, the taste, the color, and the drinkability of cider at maturity. Generally, the quality of the juice may be inferred from the outward appearance of the apple, as it departs from the spiritless white into the golden yellow and the gorgeous carnation. Hence,

"Let every tree, in every garden, own
The red-streak as supreme."

"The pippin, burnish'd o'er with gold," is but a grade below. But general rules have their exceptions, and on the present subject a surer criterion than outward show may be derived from internal examination—any apple contains a rich fluid, suitable to make a sound, palatable and exhilarating cider, which, on breaking, emits an active fragrant flavor—is not over abundantly juicy, and has a glutinous consistency. That the *crab* will make the best cider, is one of those crude conceits, that every thing is enveloped in mystery, and that we can in no other way escape the foolery which nature is playing with us, than to forsake our senses. It is all important to the full perfection of the fruit, that after having been gathered (which should be done when ripe, in dry weather, with no external injury, and before frosts shall have corrupted it,) that it be spread on covered floors to mellow, and to impart to the air an useless portion of its aqueous parts.—Rains and dews hurt ripe apples even while on the trees, but they injure them much more in heaps, or spread in contact with any substance and with each other. While in either of these situations, humidity, according to its degree and continuance, retards or stays the process of maturation, institutes that of decomposition, and impairs the spirituous quality upon which the preservation of the cider wholly depends. It should be regarded, too, as almost equally indispensable to the good quality of the liquor, that the fruit should be separated before grinding, from unripe and unsound apples, and from all filth. The juice of an unripe apple is even more pernicious than that of a defective one.

The place in which the cider shall now be set to subside is interesting to its welfare. In a cellar of uniform temperature through the year, it may be left undisturbed to settle and refine on its own lees. The unstoppage of cellar windows in the spring, admits an active agent to the acetous fermentation, against which, drawing off may be a safe guard. If placed in an open exposure below the freezing point,

"The hoary frosts, and northern blasts, take care
The muddy beverage to screen, and drive
Precipitant, the baser rosy lees."

In this case, racking before a removal into the cellar, (for it ought not to freeze) and again in March or April, may be necessary for the exclusion of the offending matter. The difference in the two modes of treatment already supposed is, that in the first, nature is left to her own unmolested operation, through which her intentions of giving to man a delectable draught, will (if they have not been thwarted by his own remissness) be effectually accomplished;—in the other, she is hastened on in her designs, and the precipitation of the performance requires, that certain of its stages should be seized to thrust

out an enemy who is only on rest to recommence commotion.

As to refining cider with matter, it may be given as a rule, that if while on the lees, or when drawn off, the liquor is tranquil, pleasant, piercing, and yet free from asperity, it may be left to itself; or, as is more fit for turbulent, acrimonious and insipid bodies, a little tasteless mucilaginous matter of any sort, as isinglass, calves feet jelly, the whites of eggs, or dissolved glue, may be infused to accelerate the precipitation of the particles suspended in the liquor.

The addition of spirit to the expressed juice is a practice condemned by *Pomona's Bard*—

"With their native strength,
Thy wine's sufficient."

A sensible observer, too, of our own, has expressed the same censure. But the subject has its qualifications. The treatment which is sometimes necessary to give a saving soundness to wine, decides against these opinions. Brandy is re-mixed with wine to give it solidity; and grapes of the greatest saccharine richness, affording a juice of nearly the consistency of honey, and easily convertible into spirit, are used to exalt inferior clusters into wine of a high quality.* In truth, it is on this point that intelligent observation must direct. Seasons of luxuriant vegetation produce a more aqueous apple than seasons of sterility. The effect of these different seasons on the quality of cider cannot have escaped notice. In the dry summers of 1805 & 6, a spiritous ascendancy in the fruit generally triumphed, in cider, over mismanagement in its making—on the contrary, in seasons of great abundance, and when the fruit is distended to a great size by the watery element, the spirit of cider is reduced to so precarious a standard, that the skilful and vigilant only may boast of its possession in power and purity. In these facts, which a moment's reflection must confirm, we have the instruction we need—if the "native strength" of the juice is sufficient, an alliance should be rejected—if insufficient, an auxiliary may be received, and as the fittest is that nearest in affinity, Cider Brandy is the most suitable assistant.

From these remarks, they result as general rules in the making of Cider, that apples should be ripe when gathered—that they should be housed to mellow—that they should be separated, before grinding, from the rotten and unripe, and from all uncleanness—that they should be mashed fine in a covered mill, and lay in must before laying up, a longer or shorter time according to the temperature of the weather, avoiding, while in that state, the least appearance of fermentation, which then almost immediately produces acidity—that the juice be purified of pulp and impurities, by passing several

* Other, and less notorious secrets in the trade of wine, give the same evidence. Currants, in the proportion of ten gallons to a barrel, will bring on a fermentation in cider which terminates in a neat and pleasant wine. It is the predominant spirit of the currants which effects the severe transformation.

A Senator in Congress, profoundly instructed in the arcana of commerce, asserted in a speech, that a composition passing any where for Madeira wine, may be formed of ten gallons of that article pure, with ten gallons of Malaga wine, thirty of Sherry, and the same quantity of Cider. An analysis of the component parts will shew, that the brandy in the sherry wine is the preservation of the cider in its assimilation to the first named ingredient.

filtrations, and be undiluted by a drop of water—that it be placed in cellars, or in colder situations, and left to its own native vigor, or aided by a friendly association, according to circumstances—that it be left "to feed awhile on its own fatness," or be drawn off once or oftener, as good judgment shall guide. With these precautions, a cider incomparably better than is made with the usual inattention, may be obtained, and its consumption enjoyed.

So far I have treated the subject with a view to general use, and in this view, a leading principle may be given in a word, alike important to the connoisseur and the unlettered tillager—it is, that nature cannot be assisted in any other way than according to her own laws.

There are some distinctions remaining, which are no other than obvious refinements of the same principle.

The exact maturity of the fruit, is the first object of attention in leaving general rules and advancing to a cider than

"Wine more priz'd, or laudable of taste."

The point of perfection in the maturity of fruit can scarcely be said to be stationary for a day; a declension from that point is as detrimental as a deficiency in its attainment; the juice loses its activity, and

"From sprightly, 'twill to sharp or vapid change."

Some apples do not mature until late in winter—others, not until the ensuing spring. Of these, a cider might be made exquisitely fine. Laid in chambers through autumn, and in dry places in the cellar through the winter, exposed to the action of the air, they become enriched by the evaporation of their watery parts—but at neither of these periods is there so friendly a concurrence of the atmosphere for the making of cider as in the last month of autumn.

Assorting the apples, (for I have yet supposed them used promiscuously) is the second particular in the progress to perfection. Phillips observes, that

"Some ciders have, by art or age unlearn'd
Their genuine relish, and of sundry wines
Assum'd the flavor."

It is not possible that a commixture of various sorts could give one distinct perception to the palate. So invariably does nature preserve each kind by itself, that no two sorts can be drawn into union on the same stock. The disagreement in the juices of fruit is more or less inveterate when mixed, as they depart from sweet to sour. The mixture of an extremely sharp acid with a luscious sweet, produces an activity of opposition approaching to effervescence, nor does it cease but with the complete subjection of the mass to the acrimonious adversary. These facts suggest the propriety and necessity of keeping each kind of fruit in its own distinctness. The conclusion I should consider as securely propped in its own reasonableness, had it never been intimated by nature nor tested by experience, *that apples of the same kind*, can make the most perfect cider. In this persuasion I can anticipate the time when cider will be designated by the name of its own apple, and the nomenclature of the orchard be as familiar in our markets as any distinctions in use. The most perfect cider, then, can alone be made by an attention to these additions to the general rules.

Of bottling, the advantages are so well understood, that I have no occasion to say any thing in their recommendation; but I should not conduct the cider-maker to the most finished point, were I to omit the observation, that a perfect fineness of his liquor, and an ascendancy in it of a spirit which shall repress its impatience in a close confinement, are as indispensably necessary to the preservation of his bottles as to the perfection of his drink.

Cider is to rise to more than an equality of fame with the most celebrated drinks of other climes, and the competition which will ensue in the market will give celebrity to the section of our country which shall be most successful in its manufacture. Already has this preference of place appeared, and our Hereford-shires and Devon-shires are in Rhode Island and N. Jersey. But it is *comparative* more than *intrinsic* excellence which may be claimed for the ciders of the Narraganset and of Newark. If the banks of the Connecticut, and the rich vales and propitious southern declivities of Massachusetts shall not bear away the palm, the fault will not be in our soil but in our sons.

"Delightful beverage! to the utmost bounds of this
Wide universe, Columbian Cider borne,
Shall please all tastes, and triumph o'er the vine."

POMONA.

FOR THE NEW ENGLAND FARMER.

The answer of "PLYMOTHEUS" in the Old Colony Memorial, to some remarks made by me on the deficiency in the description of the worm, whose ravages have been so fatal, this season, in some parts of the county of Plymouth, is highly satisfactory. It is by such clear, and distinct statements, alone, that any correct knowledge can be obtained. Loose and general remarks are of little value. It is not, to be sure, certain that we can cure these natural evils by ascertaining accurately their causes, but it is *absolutely certain*, that we *cannot* cure them *without* such information.

When Mr. Peck, (the first and ablest of our naturalists, at the period, when he first became known, and inferior to none even at this day,) gave a scientific history of the Canker worm, he afforded us the opportunity of checking its ravages, if we had followed up his suggestions. Agriculture was then in its infancy, but if at the present day, that scourge should reappear and threaten to lay waste our orchards, I am fully convinced, that the accurate and perfect account given by him of the habits of that insect, will enable us to destroy it, or to diminish exceedingly its destructive powers. The same remark may be made as to the Slug worm which affects the pear and cherry trees—many hundreds of which it finally destroyed. The knowledge with which Mr. Peck has furnished us, of its first appearance, its duration, its second appearance, the depth to which the chrysalis descends, will enable all of us to provide a remedy against its ravages. I have done it most effectually, and I have no fears of its future mischievous effects. At present our country is nearly free from them, and of course any remarks about their extermination would be read without interest.

As to the insect, still more fatal, which attacks the grass and corn, and of which "Plymotheus" has given a very satisfactory account,

as far as it was then in his power to do, it seems to me that something more is desirable—something like the accurate care and attention paid by Professor Peck to the insect above referred to. It is impossible to detect the character of insects in the worm, or as naturalists call it, the larva state. It is only in the perfect state they can be fully ascertained, viz: applied to this insect, whether this worm is a new genus, or species, or one already known. To this end, it is necessary, that some of them should be taken, and kept in earth, till they shall pass into the chrysalis, and from that into the *perfect state*, which probably, and indeed certainly, is that of a moth or butterfly. This was the course Professor Peck pursued. We shall then know at what time, they rise, as butterflies, or moths—when they deposit their eggs—when the larva or worm is hatched, and how long it continues its ravages. To what depth the larva descends, in order to undergo its change. It is indeed very alarming, if it descends three or four feet, as stated by Plymoutheus—but we must doubt this fact, until we know, that the identity of the worm on the surface, and that found in digging post holes, has been ascertained. Great credit is due to Plymoutheus for what he has done; but we view it only as a pledge, that for the public good, he will do more, which we feel convinced he is very competent, and very ready to do. There is little doubt from his description of the effects of this insect, and of the *mode* of doing injury, that it is the same insect, which appeared in Worcester county, and the western parts of this state, three years since, and partially on some estates, in Roxbury. The singular manner, in which the grass sward was undermined, so as to detach it from the soil, and to enable you to roll it up, seems to identify it, with the insect so destructive, and alarming to us, at the period referred to. If it could be conceived that such an insect should be permitted to prevail over the country generally, it might produce a famine, though we apprehend, that there is little hazard of such an event—but it is very important, that we should trace its history with care, and we shall doubtless be able to find means of destroying it. We should always remember, as farmers, that this fertile earth is given to us on the condition of our perpetual and never ceasing care to preserve its fertility, and that all the evils we encounter, dry seasons, devouring insects, and blights, are only intended to sharpen our intellectual faculties, increase our zeal and industry in the effort to surmount them, and thus in the end to render the earth more prolific, than it would have been if no such stimulus had existed.

A FARMER.

Roxbury, Sept. 25.

Extract from Pliny's Natural History, Book xviii.
[Translated for the New England Farmer.]

Caius Furius Cresinus, a freed man, was hated, and suspected of sorcery, by his neighbors, because he raised more from his small farm than they acquired from their large possessions. A day was appointed for his trial, by Spurius Albinus. Fearing condemnation, before the opinions of the people were asked, he brought into the forum his farming implements, and his healthy family, well taken care of and neatly dressed, (as Piso relates) tools excellently made, spades and plough-hares, and even in good con-

dition. "These, O! Romans, said he, are my enchantments. My watchfulness, diligence and labor, I cannot display before you." He was acquitted by an unanimous vote. Truly it is labor, not expense, that makes a plentiful harvest; and it is an ancient adage, that the best manure is the eye of the master.

From the American Farmer.

THE ROLLER—Its use and Importance.

MR. SKINNER—Looking accidentally into the Encyclopedia Britannica, at the article Agriculture, I found the annexed passage, which you may think deserves to be inserted in your paper, as I do myself, because we suffer in this part of the country, from frequent droughts, and the relief alluded to in this article is not generally known, though certainly no recent invention or discovery.

Your obedient servant,

THOMAS W. GRIFFITH.

The Roller is an instrument of capital use in husbandry, though scarcely known in ordinary practice. "In the first place, rolling renders a loose soil more compact and solid; which encourages the growth of plants, by making the earth clap close to every part of every root. Nor need we be afraid of rendering the soil too compact: for no roller that can be drawn by two or four horses will have that effect. In the next place, *rolling keeps in the moisture, and hinders drought to penetrate*. This effect is of great moment. In a dry season it may make the difference of a good crop or no crop, especially where the soil is light."

☞ Allow me to take this opportunity to recommend to all road makers, the use of an instrument of the kind alluded to, that is, a *roller*, to press down the materials employed in making roads, *before the same is travelled*—a practice which was successfully adopted, on my suggestion, by the President and Managers of the Turnpike from Baltimore, towards York, in Penn. some years ago.

T. W. G.

From the Cooperstown, (N. Y.) Journal.

Washington's opinion of Agricultural Societies.

I like occasionally to converse with the mighty dead; the results of their investigations, are so many beacons to guide and direct those who come after them. Washington was indeed the father of this country, and he has left many testimonies of his wisdom and devotion to its best interests. At this day, there can be found no man who has the temerity to impugn the motives by which he was actuated, or doubts the policy of the measures which he urged upon the consideration of the National Legislature. In a speech at the opening of Congress, in December, 1796, I find he recommended Agriculture as one of the most proper objects of public patronage. It will be seen by the following extract from that paper, that Societies for the encouragement of the parent art, were considered of primary importance, and especially deserving the fostering support of the National Government.

It will not be doubted, that with reference either to individual or national welfare, Agriculture is of primary importance. In proportion as nations advance in population and other circumstances of maturity, this truth becomes more apparent, and renders the cultivation of

the soil more and more an object of public patronage. Institutions for promoting it, grow up, supported by the public purse: And to what object can it be dedicated with greater propriety? Among the means which have been employed to this end, none have been attended with greater success than the establishment of Boards, composed of proper characters, charged with collecting and diffusing information, and enabled by premiums and small pecuniary aids, to encourage and assist a spirit of discovery and improvement. This species of establishment contributes doubly to the increase of improvement, by stimulating to enterprise and improvement, and by drawing to a common centre the results, every where, of individual skill and observation, and spreading them over the nation. Experience, accordingly has shown, that they are very cheap instruments of immense national benefit."

From the New-Hampshire Patriot.

The corn is at this time ripe in the fields just fit for the harvest; and New-Hampshire never exhibited finer and heavier fields—it is believed all was out of the way of "Jack Frost" when he commenced his attacks. Potatoes, turnips and almost every kind of vegetable, have been attended by a growth, whose luxuriance was scarcely if ever exceeded. But the apple trees—we scarcely know how to describe their appearance:—it would seem as if the whole growth of some trees could be intended to produce only one year's crop like the present; there appears to be, at least, a crop of three ordinary seasons in one. Farmers, in laying in their store of cider, ought to calculate for not less than two years. And not only there are more in number, but the size of the apple is increased. To the south, larger fruit of most kinds is produced than to the north: this may be seen in the orchards of Massachusetts contrasted with those of New-Hampshire. The largest apple we have had any account of the present year was one at Marblehead, which weighed about 23 ounces. In the orchard of Maj. Stark at Danborton last Thursday one of the editors picked up four apples lying side by side as they fell from the tree, which weighed more than three pounds; and Mr. Gale of this town shewed another weighing a little over seventeen ounces.

POTATOES were discovered in Virginia, by Sir Walter Raleigh who imported them into England previously to 1590. In a manuscript account of the household expenses of Queen Anne, wife of James I. who died 1613, the price of potatoes is given at one shilling a pound.—They now sell fourteen pounds for sixpence. They were not introduced into Ireland till 1610, nor into Scotland until 1728, except in gardens. How rapid and extensive has been the growth and consumption of this root in the course of one century.

Camp Meeting.—A camp meeting of the Methodists commenced about five miles from Plattsburgh, N. Y. on the 5th and closed on the 9th ult. About 5000 were present. During its continuance, the whole country was in motion, and every species of land and water transportation was in requisition.—The society numbers more than 100 new converts at this meeting.

N. E. FARMER.

BOSTON.—SATURDAY, OCT. 5, 1832.

It is hoped that the valuable original communications, published in this day's paper, will atone for the want of original matter under the editorial head. We had articles prepared, which were omitted to give room for the official account of the proceedings at the Worcester Cattle Show.

CATTLE SHOW AT CONCORD.

The *Middlesex Society of Husbandmen and Manufacturers*, held their Anniversary at Concord, on the 3d inst. It was attended by a large and respectable assemblage of the substantial yeomanry of Massachusetts, and many characters of the first respectability honored themselves as well as the occasion, by being present, and taking an active part in the business and amusements of the day. We hope to receive an official account of the proceedings at this Exhibition, for our next paper.

Hillsborough, N. H. Cattle Show.—An Agricultural Fair and Show was held at Amherst, on the 24th and 25th of September, which is spoken of in high terms. The *New Hampshire Patriot* says, "Without disparagement to any other exhibition, it may in truth be said that the patriotic County of Hillsborough has this year, not only out-done all her sister Counties, but excelled herself on any former occasion. This has resulted from the extended and liberal principles on which the Society has been managed, and from the prompt attention of its individual officers and committees to their respective duties—in particular, from the unwearied labor and perseverance of its Secretary, EDMUND PARKER, Esq. to whom the Society owes much, and has acknowledged its obligations."

"The cattle were remarkably fine, especially the young bulls, steers and heifers. Gentlemen from Massachusetts who had frequently attended the great exhibitions at Brighton, freely admitted they had never seen any cattle there superior to those which were reared on the high grounds of the county of Hillsboro'. There was not so great a variety of the household manufactures as might have been anticipated; but better samples have not probably been exhibited. The butter and cheese were excellent—the woollen cloths would vie with superfine imported—the plain linens and diapers, the grass and straw bonnets, the carpets and flannels did great credit to the fair hands which wrought them. In short, there was scarcely an article exhibited which failed of discovering the improved taste and genius of the people of this county."

There were nine persons competitors in the Ploughing Match, and each ploughed the lot assigned him, of one eighth of an acre, in the following manner—Benj. Parker in 13 min. 5 sec.—John Johnson in 13 min. 8 sec.—Isaac Burns in 14 min. 45 sec.—Jonathan T. Wheeler in 15 min. 30 sec.—Levi Jones in 15 min. 25 sec.—Daniel Fuller in 16 min. 25 sec.—C. H. Atherton, one yoke, in 17 min. the other, in 20 min. without a driver—Timothy Danforth in 17 min. 30 sec.

At half past 12 o'clock, at the Meeting House, after prayers by the Rev. Mr. Lord, an ingenious and pertinent Address was delivered by Moses Eastman, Esq. of Salisbury. The awards of the several committees were then declared and the premiums paid.

After the premiums were declared and paid, the Rev. Humphry Moore, of Milford, Chairman of the Viewing Committee, read a report which he had prepared. It gave a concise description of the Farms and Crops viewed, and the management and good husband-

ry of the owners. The Amherst Cabinet declares that "it was replete with information and wit, and filled the audience with delight and admiration." The same paper says that "the expediency of having the Show in the pleasant month of September, instead of October, and of having two days instead of one, has been decidedly manifested. A large number of new members has been added to the Society, and we have heard of but two who even thought of taking a dismission. As good a Show as we have now had can always be had for \$100, and we hope four hundred good farmers can be found in the county, wishing to contribute yearly the sum of one dollar each, thereby adding ten fold to the respectability of their own class and occupations."

FOREIGN.

DEATH OF LORD LONDONDERRY.

The packet Ship *Amity*, Maxwell, has arrived at New York, with London papers to the 14th of August. They do not appear to contain any thing of importance, if we except the death of the Marquis of Londonderry, who committed suicide by cutting his throat on the 12th of August, at North Cray, County of Kent. The *London Courier* of the 14th contains the Coroner's Inquest and Verdict, from which it appears that he was in a fit of insanity when he committed the act, which was produced by extreme mental and bodily fatigue during the late session of Parliament.

On the death of Lord Castle-rough, the editor of the *Liverpool Mercury* observes, "The sudden, unexpected and self-inflicted death of this nobleman absorbs the public attention to the exclusion of almost every other topic, not excepting the Royal visit to Scotland—nor do we wonder at the interest excited by the demise of an individual, who was the very soul of the present administration; and whose memory is so inseparably associated with the crooked policy pursued by the British Cabinet for the last quarter of a century, that it will be 'damned to everlasting fame.'"

His death was announced in London about half past one on the 12th, and produced great confusion and agitation at the different government offices. It had the effect of lowering the funds a half per cent.

The verdict of the Coroner's Jury was, "That on Monday, Aug. 12, and for some time previously, the most noble Lord, Marquis of Londonderry, under a grievous disorder did labor and languish, and become in consequence delirious and of insane mind; and that whilst in that state, with a knife of iron or steel, he did inflict on himself on the left side of his neck, and of the carotid artery, a wound of one inch in length and a half an inch in depth, of which he instantly died; and that no other person except himself was the cause of his death." To this verdict, all the jurors signed their names.

Eight days later.—By an arrival here on the 2d inst. London papers have been received as late as the 22d of August. The Greeks continue a successful opposition to the Turks, and have threatened measures of retaliation for the cruelties committed at Scio, which it is thought will operate as a restraint on the barbarity of the ferocious Ottomans.

In Spain the waves of political commotion appear to be fast subsiding. Accounts to the 14th of August have been received in London, which state that the new ministry was firmly established, and that they gave such indications of talents, energy, and liberality as led to sanguine hopes that order will be restored, and the country tranquilized. At Cadiz every thing was quiet, and the Constitutionalists completely victorious.

A Congress of Sovereigns was to hold a session at Verona in August, and hopes were entertained that measures would be adopted by those potentates for the benefit of Greece.

The Marquis of Londonderry was buried with great pomp and magnificence in Westminster Abbey. His successor in office will not be appointed till after the return of the King from Scotland.

The reception of the King at Edinburgh, was every way worthy the Scottish character, and gave infinite satisfaction to his majesty.

DOMESTIC.

Mr. Benson, of Galloway, N. Y. has received premiums from the Agricultural Society of Saratoga county, for having raised 62 bushels of Bailey on an acre—four and one half tons of Timothy Hay, per acre, on eight acres—101 bushels of Corn on an acre—and also the largest crop of Potatoes in the county.

The crops of Rice in the vicinity of Savannah are uncommonly abundant and of good quality. About one half of the crop was supposed to have been harvested previous to the 14th Sept.

A person by the name of Richard David, residing in Indiana, was lately bit by a rattle-snake in so fatal a manner, as to cause his immediate death.

Last week, (says the *Gazette*,) on the complaint of the Police Officer, one of our butchers was convicted, before the Police Court, of offering for sale, at the Bayston Market, raised and stuffed meat, contrary to a city ordinance passed on the 22d July last, and fined five dollars and costs. This being the first conviction under the law, the Court sentenced the offender in the smallest penalty, but intimated a determination to increase the fine on future convictions.

BRIGHTON SHOW AND FAIR.

The Members of the Massachusetts Society for Promoting Agriculture, will please bear in mind, that their attendance is expected at their Hall, in Brighton, on *Wednesday*, the 9th of October, at 9 o'clock, A. M. as business is to be transacted—the admission of new members, &c.

All those Gentlemen who are appointed on Committees, will please be punctual in their attendance, at 9, A. M. of the days on which their particular duty falls, as the Trustees intend to adhere strictly to their Rules and Regulations.

Those Ladies who wish to view the Manufactures in the Hall, will please to observe, that they must ascend to it by the steps at the South End, outside of the building, and that the same will be devoted exclusively to them on the 9th, from 9, A. M. to 12, A. M. Some of the Trustees will attend them, and no other Gentlemen will be admitted during those hours, except the owners of the goods, who are expected to exhibit and attend to them.

After 12 o'clock of the 9th, the Hall of Manufactures may be visited by Gentlemen.

The Galleries of the Meeting-House will be reserved for Ladies, till the procession enters, at 1 o'clock. The doors will be open for them exclusively, at 11 o'clock.

Any Gentlemen having fine Animals that are not entitled to be offered for premium, or that have previously received them, are requested to exhibit them, and Pens will be provided.

A Dinner will be provided at Dudley's Hall; a few tickets for which, at one dollar and fifty cents, are deposited at Wells and Lilly's, Court-street, till the morning of the 9th, after which they will be with Mr. Kuhn, at the Society's Hall, in Brighton; and where, also, those Members of the Society, who have not received their diplomas, can obtain them.

Any Gentlemen having fine specimens of Grain or Vegetables, will please deposit them in the lower Hall; also, any new Agricultural implements, which they may think deserve notice, stating on a card their quality.

It is requested of Gentlemen having fine Fruit, to deposit some with Mr. Dudley, for the Agricultural Dinner, attaching their names to the same, which offerings will be duly noticed by the company.

Per Order, GORHAM PARSONS.

BY T. G. LESSENDER.

*Uate not laborious work, neither husbandry, which the
Most High hath ordained.....Ezek. Apecc.*

Although some men, with pride elate,
Can't condescend to cultivate
The life-supporting soil,
The HIGHEST husbandry ordain'd,
Nor can the proudest be sustain'd
Without the Farmer's toil.

If Adam, in his sinless state
Was well employ'd to cultivate
The soil, which gave him birth,
One would suppose his sinful race
Would not esteem it a disgrace
To till the fruitful earth.

Yet many a hale and brawny lout
Wont stoop to set himself about
So noble an employment!
In doing mischief, doing nought,
And doing nothing which he ought,
Is plac'd his whole enjoyment.

Some dolts as stupid as a stump,
Have had the happiness to thump
Their pates against a college;
Can construe, possibly, *quid agis?*
And therefore think themselves great sages,
Quite prodigies of knowledge.

Others, perhaps, still greater bores,
Have learn'd the odds, in merchants' stores,
'Twixt muslin and molasses;
But still for manners, means and mind,
Rank with those brutes, he wish'd to find,
Who sought his father's asses:

Yet, being *gentlemen by trade*,
They will not touch an axe or spade,
But, useful labor shunning,
They lounge about in lazy hands,
Throng tippler's shops and tavern stands,
Like rattle-snakes a sunning.

And some the learn'd professions crowd,
Whose shallow pates are not allow'd
To take in two ideas;
Their feeble wits for years they task,
Ere pride will suffer them to ask
What nature's fix'd decree is.

All these, a poor mistaken race,
Think husbandry a great disgrace,
Though Washington thought not;
And hands which empire's rod could wield,
Have been employ'd to till the field,
And bless'd their happy lot.

Now these our lays are not design'd
To undervalue men of mind,
Nor fruits of intellect;
The learn'd professions we would fill
With men of science, sense and skill,
Most worthy high respect.

Still, those professions, 'tis allow'd,
Are sadly cumber'd with a crowd,
A nice but needy train,
Oblig'd to tax their brains with double
A common farmer's toil and trouble,
A livelihood to gain.

Merchants are useful in their places,
But if society embraces
Too many of the caste,
As sure as man's to trouble born,
Straight through the small end of the horn
Some must be squeez'd at last.

Reader, I don't pretend to say
But what *your* eminency may

Be bless'd with parts uncommon;
A better head and heart, perhaps,
Than commonly since Adam's lapse,
Are own'd by man or woman.

It does not follow thence, however,
Your hands, so delicate, must never
Perform "laborious work;"
That you should loiter life away,
And vegetate from day to day,
As lazy as a Turk.

You are, perhaps, by mother wit,
As well as education fit
Some famous part to act;
But it is possible there may
Be other great men in your way,
As good as you, in fact.

And if you've reason to suspect
The higher toils of intellect
Are not for you decreed;
Your hands, in useful labor plied,
May, with God's blessing, still provide
For every real need.

Then swing the axe, or ply the spade,
Or work at that mechanic trade
Which suits your genius best;
Become a tinker, rather than
A mischievous, or idle man,
A nuisance or a pest.

And shun those imps, with pride elate,
Who cannot stoop to cultivate
The life-supporting soil;
And contravening God's commands,
Will not employ their heads nor hands
In any useful toil.

From the Boston Daily Advertiser of October 1.
AGRICULTURAL INTELLIGENCE.

The season has been unusually fertile—Indian Corn, our great staple has rarely been better or in greater abundance. All vegetables have flourished unusually well, and the crops are great.—Still it must be admitted to have been a season beyond all example, dry. The springs are lower than they have been for thirty years. A pond which has been full to overflowing for thirty-five years, has been for six weeks past, two feet below its ordinary level. Many wells have failed, which were never known to fail before. The after feed is nearly cut off, and the effects will be felt next spring in the high price of hay, unless we are supplied from the Eastern shore, where the season has been more favorable.

Apples are more abundant and larger and fairer than we have ever known them, but we fear they will be preserved with difficulty. They will ripen prematurely, and cannot be preserved till spring without great care. The use of these hints will be perceived, if those who raise, or buy winter fruit, will in consequence of this intimation, take unusual care in picking their fruit and in its preservation. As the apples are so ripe and of course the skin so soft, it will require more caution to prevent bruises in picking them, which are always fatal to the fruit. Purchasers buy apples by the barrel without inquiring into the *manner* in which they have been picked and put up. Yet one barrel well picked, is worth two carelessly managed. When put up in such a season particu-

larly, and in all seasons, they should be kept as cool as possible.—Any degree of cold short of freezing is not only not injurious but highly beneficial to fruit intended for winter use.—Pears have been fairer and finer this year than for ten years past, but they ripen, and rot much earlier than usual. They should be exposed to the greatest possible degree of cold. It is not probably generally known that winter fruit can be preserved in ice houses till August in perfection, and that cherries and other summer fruits can in like manner be kept perfect for many weeks, long after their season is past.

The sweet potato has flourished this season beyond expectation. It is very sweet and dry—full as good as those raised in New-Jersey, and we think better. We have had them in perfection for seven weeks, since the 6th of August—and on one eighth of an acre, we have raised enough for our own wants, and have been able to send to market what will pay the whole expense. Our neighbours, who attempted to raise them, we are sorry to perceive, have failed, owing partly to the unusually severe, and early frosts of the past week, but more particularly to the injudicious selection of southern seed. They procured them from Virginia instead of New-Jersey. This, like all other plants, must be (to use a southern phrase,) *acclimated*. The peach and cherry were gradually introduced into northern regions. If we should import a peach tree direct from Armenia or Persia, its native region, it would never ripen its fruit with us. It is only by very gentle transitions that we procure in perfection fruits not natural to our soil.

A ROXBURY FARMER.

From the Connecticut Mirror.

Mrs. Wells of Wethersfield, (formerly Miss Woodhouse) has received by the hands of Mr. Marcus Bull of this City, the Medal and twenty guineas which were awarded to her by the British "Society of Arts," for her ingenuity in the manufacturing of the splendid Bonnet, which Mr. Bull carried to London. We have not seen the Medal, but we understand that it is of perfectly pure silver, of about the circumference and twice the thickness of a crown—with various emblematic devices, elegantly executed on one side, and on the other a short inscription stating who gave it, to whom it was given, and for what reason.

In remarking on the new material for fine straw plait, the Connecticut Courant says—
"The importance of this discovery to that country will be readily perceived, when we state that not less than one hundred thousand females, who have been formerly employed in the manufacture of Straw Bonnets, are now either partially or wholly deprived of their only means of obtaining a reputable subsistence.—From the experiments already made in cultivating the grass in England, no doubt remains as to its success; and we may say with safety, that in giving this discovery to our mother country, we make her a valuable return in the account of reciprocating national discoveries and improvements. We sincerely hope that the importance of this discovery to our own country may not be lost sight of; but that immediate and extensive establishments may be formed for the manufacture of domestic Leghorns, as we cannot doubt that such establishments would meet with a liberal support from all classes of society.

NEW ENGLAND FARMER.

CATTLE SHOWS.

From the Middlesex Observer, of Oct. 5.

MIDDLESEX CATTLE SHOW.

The Society of Middlesex Husbandmen and Manufacturers held their annual fair in this town, on Thursday last.

The day was fine, and the number of citizens present from various parts of the county, gave pleasing evidence of the increasing interest taken in these useful exhibitions. At about half past 10 o'clock a procession, composed of the members of the Society and others, proceeded from Mr. Darrah's Hotel to the Meeting-house, where, after a very appropriate supplication to the Throne of Grace, by the Rev. Mr. Field of Weston, an Address was delivered by Mr. Fessenden. As it is expected this Address will be published, we will make but a single remark concerning it, viz. that it fully answered the highest expectations of the audience.

The procession then moved to the Court-house, where the Committee on Manufactures proceeded to examine the numerous articles presented for inspection. The remainder of the procession moved to the field, on which the pens for the reception of animals were erected, and which were well filled. Among the many fine animals which we noticed, we cannot help making particular mention of a superior yoke of steers, (four years old) belonging to Mr. Josiah Hayward, of Westford, and a fat ox, (five years old, wt. 2000) belonging to Mr. Amos Davis, of Groton.

After the animals, manufactures, &c. had been inspected by the respective Committees, a company, consisting of nearly two hundred, partook of an excellent dinner provided by Mr. Darrah.

The repast was concluded by drinking the following toasts, accompanied by a select band of music.

1. The Commonwealth of Massachusetts—She knows where her strength lies—she has patronized agriculture and domestic manufactures.
2. Agriculture the first employment of man; the promise of seed time and harvest was made to such, and to such only as put their hands to the plough and look not back.
3. American Manufactures.—Their superiority is proved by English imitators. We'll show them a yankee trick by and by.
4. The farmer and mechanic, while they pay direct taxes, unequal in their operations, will find some "specific" to render them equal.
5. The farmers' and manufacturers' holiday.—They have driven from the field dice-boards and puppet-shows, and have made the most useful exhibitions a feast of pleasure.
6. Our brethren of South America.—They have sacrificed the firstlings of their flocks to liberty—we offer them the right hand of fellowship.
7. Our fair country women.—Let your daughters be educated for domestic housewives, and there will be less show, more substance, and fewer old bachelors.

By the President of the Society.

The Governor of this Commonwealth—The tried patriot—the gallant soldier.

By General Parker.

The encouragement of domestic manufactures—the only system of finance that can equalize our currency, and balance the annual forty millions of surplus importations.

By John Keyes, Esq. one of the Committee of Arrangements.

The Orator of the day—The doctrines he has this day taught us should operate like *quick-lime*, and quicken us in our duty.

At four o'clock, the several Committees repaired to the Court-house, when the premiums were announced by the Secretary. Among the manufactures we noticed with pleasure an elegant carpet, wrought by Mrs. Pitts, of Chelmsford, a fine straw bonnet, the production of Miss Dalrymple, of Marlborough; and a beautiful imitation Leghorn, made by Miss Sherman, of the last mentioned town.

We likewise saw 4 beets, the average weight of which exceeded thirty pounds; a cornstalk, containing five large ears of corn; some very large apples, though none of the latter equalled the New-York two pounder.

The performances of the Harmonic Society of this town, at the Meeting-house, and of the musicians who volunteered their services as a band on the occasion, were deservedly well spoken of.

The several Committees awarded the premiums as follows, viz.—

- To Capt. Uriah Manning of Woburn, for the best Bull, \$15
- To David Perham, of Chelmsford, for the next best, 8
- To Benj. Wheeler, of Framingham, for the best bull calf, 4
- To Josiah Hayward, of Westford, for the best working Oxen, 12
- To Edward Wetherbee of Acton, for the next best do. 6
- To Paul Adams, of Concord, for the best Milch Cow, 10
- To Paul Adams, of Concord, for the best H. lifer, 8
- To Benj. Wheeler, of Framingham, for the next best, 4
- To Amos Davis of Groton, for the best fatted Ox, 10
- To Wm. Brown, of Concord, for the next best, 7
- To Nathl. S. Bennet, of Framingham, for the best Bear, 4
- To Cyrus Hubbard, of Concord, for the best Sow, 3
- To Zadock Rogers, of Tewksbury, for the best pigs, four in number, 3

Cotton, Woollen, and Linen Manufactures, &c.

- To Mr. Shepherd, of Watertown, for the best piece of Broadcloth, 15
- To the Rockbottom Manufacturing Company of Marlboro' for the next best, being of mixt, 5
- To Stephen Buttrick of Framingham, for the best piece of plain cloth, 5
- To Josiah Melvin, of Concord, for the next best, 6
- To the Rockbottom company, for the best piece of Kerseymer, not less than ten yards, 4
- To Eli Brown, of Concord, for the best piece of Flannel, not less than 20 yards, 6
- To Miss Mary Hurd, of Lincoln, (6 years of age,) for a coverlet, 6
- To Mrs. Pitts, of Chelmsford, for the best piece of carpeting, 1
- To Mrs. Benjamin, of Concord, for the next best, 6
- To Miss Betsy Whitcomb, of Boxboro' for the best woollen coverlet, 3
- To Mrs. Benjamin, of Concord, for the next best, 4
- To John Buttrick, of Concord, for the best woollen blankets, 2
- To Ephm. Osborn, of Dracut, for the best piece of linen diaper, 4
- To Nehemiah Hunt, of Concord, for the next best, 3
- To John Butman, of Tewksbury, for the best woollen hose, 2
- To Miss Emily Wheeler, of East Sudbury, for the next best, 2
- To Kendall Bailey, of Charlestown, for Morocco Skins, 1

- To Abel Moore, of Concord, for the best pair of Boots, 2
- for the best pair Ladies' shoes, 1
- for the best pair men's calf skin do. 1
- To Wm. Parker, of Pepperell, for the best Foolscap Paper, 2
- To Joshua Puchee, of Acton, for the best hogheads, 3
- for the next best, 2
- To Simon Tuttle, of Acton, for the best barrels, 3
- To Daniel McClenning, of Littleton, for the next best, 2

Inventions, improvements in Machinery, improvements of Husbandry, and all Manufactures, &c. not specially committed to any other committee

- To Mrs. Sarah Hovey, of Acton, for a most ingenious and elegant specimen of silk twist buttons, 2
- To Miss Sarah Hovey, of Acton, (7 years of age,) for an elegant specimen of ribband, 1
- To Alvan Pratt, of Concord, for a finished Rifle, 2
- To Ezra Warren, of Chelmsford, for a huge Plough, 5
- To Reuben Miles, of Concord, for a Churn of his own invention, 3
- To Comfort Foster & Co. of Concord, for 3 water proof Hats, 3
- To James Cogswell, Jr. of Concord, for 3 water proof Hats, 2

The committee on Leghorn and Straw Bonnets report that they have examined several fine specimens of Straw Bonnets, and two of such fine and remarkably nice work, and both so exceedingly well executed that they are unable to say which ought to claim the first premium—they therefore award the same premium to each.

- To Miss Dalrymple, of Marlboro' for two Straw Bonnets, 2 50
- To Col. Joseph Valentine, of Hopkinton, for Bonnets, 2 50
- To Miss Betsy Bennet, of Framingham, for a Leghorn, or grass Bonnet of nice workmanship, 2
- To Miss Sherman, of Marlborough, for a Leghorn Bonnet, 2

The Committee would express the pleasure they enjoyed at finding several other Bonnets of beautiful workmanship; and though they cannot award premiums to all, yet they hope those who have exhibited this day will not be prevented from sending such excellent manufactures to other exhibitions.

The Committee have examined a specimen of Leghorn straw, from wheat imported from Tuscany, by Hon. Samuel Dana, and another specimen, cultivated by Dr. Spalding, of Amherst, N. H. and also a sample of Leghorn straw braid, which give evidence of the increased attention of our agriculturalists to this important article. Your Committee cannot award premiums to the above, yet they would feel disposed to do so, did the funds of the Society permit it.

The Officers chosen by the Society for the ensuing year are

- DAVID LAWRENCE, Esq. President,
- HON. CALVIN SANGER, 1st Vice President,
- COL. JOSEPH VALENTINE, 2d do.
- JOSIAH ADAMS, Esq. Cor. Sec'y,
- NATHAN BROOKS, Esq. Rec. Sec.
- COL. D. SHATTUCK, Treas. & Collector.

From the Salem Gazette of October 4.

ESSEX AGRICULTURAL EXHIBITION.

The Annual Exhibition of Cattle and Manufactures, for the County of Essex, was at Tops-

field on Wednesday last. The day was favorable; the assemblage of people large, and highly respectable.

The number of competitors for premiums was much less than in the last year; and the show of animals (with some exceptions) much inferior. The whole number of animals exhibited for premiums, was about one hundred. It is to be regretted, that in a county possessing so many fine animals, so few of the inhabitants should have public spirit enough to bring them forward. The fear of not being considered first, operates to destroy all the advantages arising from competition.

Premiums were awarded

To Mr. Josiah Lovett, of Beverly, and Capt. Stephen Abbot, of Andover, for the management of a Dairy.

To Mr. Aaron Perley, of Boxford, for the best Cider made in 1821.

To Mr. Benjamin Savary, of Newbury—to Col. Sohn Brocklebank, of Rowley—to Mr. Joseph Osgood, of Danvers—to Billy Emerson, Esq. of Topsheld—to Col. Jesse Putnam, of Danvers—to Samuel Chadwick, Esq. of Bradford—to Isaac Osgood, Esq. of Andover—to John Torrey, of Newbury—to Richard Crowninshield, of Danvers—to Gideon Foster, Esq. of Danvers—to Samuel Hood, of Topsheld—to Hon. Samuel Putnam, of Danvers—to Tristram Brown of Ipswich, for the best Cattle.

To widow Jane Swan, of Methuen—to Susan Young, of Byfield—to Mrs. Crowninshield, of Danvers—to Mrs. Betsey Merrill, of Salisbury—to Mrs. Hannah Perley, of Boxford—to Mrs. Abigail Bracket, West Newbury—to John Hale, of Boxford—to Ebenezer Burnham, of Ipswich, for Domestic Manufactures.

There were exhibited some large and fine vegetable productions. Some corn from Newburyport and Haverhill, the seed of which came from the Indians in the upper part of the Missouri country; and which promises to be a valuable kind of cultivation.

The field for the Ploughing Match was a green sward, laid out in lots 20 rods long and 2 rods wide, containing one quarter of an acre.—The work was well done, and the performance satisfactory to a numerous crowd of witnesses.

The first premium was given to John Brocklebank, of Rowley.

The second premium was given to Benjamin Savary, of Byfield, from the farm of Gorham Parsons, Esq.

The third premium was given to Joel Wilkins, from the farm of Judge Putnam, in Danvers.

A very large number of claims for premiums on Indian Corn and other Crops, and four on the management of a farm, have been entered with the Secretary.

After dinner the members of the Society and others repaired to the Meeting-house, where an excellent, ingenious and pertinent Address was delivered by the Rev. Dr. Eaton, of Boxford.

From the Massachusetts Spy of October 9.

WORCESTER CATTLE SHOW, &c.

(Continued from page 75.)

The Committee on *Manufactures of Cotton and Woollen*, consisted of Hon. Benj. Adams, of Uxbridge, Chairman; Mr. Phin. Bemis, of Dudley, Mr. George Hall, of Mendon, Joseph Bowman,

Esq. of New-Braintree, and Nathaniel Maccarty, Esq. of Worcester. The Committee expressed their deep regret that the goods which fell under their observation were so deficient in quantity, though of good quality. They assigned some of the reasons which, in their opinion, had occasioned the neglect so apparent among our manufacturers, and suggested a remedy. Their report will repay an attentive perusal. They recommended the following premiums:—

To Messrs. Goodale and Co. of Millbury, for the best superfine Broadcloth, of sufficient quantity, \$15
To the Walcott Manufacturing Company, for the best Cassimere, 10
To Sarah Patrick, of Worcester, for the best Carpeting, 15
To Adolphus Bartholomew, of Hardwick, for the next best, 10
To Lovett Peters, of Westborough, for the best Flannel, 10
To Nathaniel P. Denny, of Leicester, for the next best, 5
To Jonathan Mann, of Worcester, for the best Woollen Cloth, of Domestic Manufacture, 8
To Stephen Shepherd, of Berlin, for the next best, 5
To Levi Sawyer, of Bolton, for the best Woollen half Stockings, for men, 2

The Committee mentioned in terms of commendation several articles of superior quality. viz. a piece of Superfine Broadcloth by the Walcott Manufacturing Co. which was deficient in length; a beautiful piece of Flannel, made by Miss Clara Fay, of New-Braintree; another piece, by Mrs. Martha Lincoln, of Worcester; some well knit Woollen Stockings, by a blind woman; another pair, by a woman of 90 years of age, and another pair by one 83 years old; a piece of beautiful blue Sattinet, by Leonard Legg & Co. of Grafton; some handsome Hearth-Rugs, by Miss Sally Penniman, of New-Braintree, and Miss Mary B. Warren, of Leicester; and some pairs of Rose Blankets by Miss Fanny Pierce, of New-Braintree, and Mrs. William McFarland, of Worcester.

The Committee on *all other Manufactured Articles besides those of Cotton and Woollen*, consisted of Bezaleel Taft, jun. Esq. of Uxbridge, Chairman; Col. Henry Sargent, of Leicester; Mr. James Walcott, jun. of Southbridge; Mr. Henry M. Sikes, of Worcester; Mr. Royal Keith, of Grafton; and Col. Henry Penniman of New-Braintree. This Committee remarked upon the importance of exciting a greater spirit of emulation than seems at present to exist among our ingenious Mechanics, who have it in their power to do so much, and who yet content themselves to do so little. They recommended the following premiums:—

To Anna R. Putnam, of Grafton, for the best piece of Linen Shirting, \$5
To Jabez Brigham, of Worcester, for the next best, 3
To Nathan Stone, of Ward, for the best Linen Diaper, 8
To Lemuel Healy, of Dudley, for the best specimen of Sewing Silk, 10
To Harmon Chamberlin, of Worcester, for two Linen damask Table-Cloths, 2
To Abigail Hapgood, of Shrewsbury, for a Straw Bonnet, 3
To Benjamin Read, of Templeton, for the best Sole Leather, 10
To Joseph Griggs & Co. of Millbury, for the best Calf Skins, 10
To John Aspinwall, of Millbury, for the best Morocco, 6
To Stephen Hastings, of Sterling, for the best Butter, 7
To Oliver Barrett, of Bolton, for the next best, 5
To Philemon Wright, of Worcester, for the next best, 3

To Francis Grout, of Worcester, for another specimen, 2
To Ebenezer Tidd, of New-Braintree, for the best Cheese, 10
To Wm. Earl, of do. for the next best, 5
To Seth Goddard, of Holden, for some excellent Barrels, 1
To Josiah Rice, of do. for same, 1

The Committee particularly mentioned several articles as worthy of praise, to which it was not in their power to award premiums, viz. a piece of Linen Shirting, by Sibil Wilcox, of New-Braintree; a Straw Bonnet, exhibited by Elias Whitney, of Lancaster; one by Jonathan Wood, of Worcester; one by Martha Ware, of Shrewsbury; and one by Miss Green of Mendon; some very nice Maple Sugar, by Mr. King, of Hardwick; a superb Fowling Piece, by Silas Allen, of Shrewsbury; a Patent Time-Piece by Simon Willard, of Roxbury; some superior Hats, by Joseph F. Seaver, of Northborough; an elegant Covering to a Musick Seat, by Mrs. Elizabeth Davis, of Worcester; a tasteful specimen of Needle Work, by Miss Lincoln, of Worcester; some well manufactured Sole Leather, by Mr. Davis, of Northborough; Calf-Skins, by Messrs. Davis; Morocco, by Messrs. Griggs & Co. and by the Ashburnham Leather Manufactory; and specimens of excellent Butter and Cheese too numerous to mention.

The reports of the respective Committees were accepted by the Trustees, and the premiums recommended, were awarded accordingly.

The Address of NATHANIEL P. DENNY, Esq. will be published under the direction of the Trustees, as soon as it conveniently can be, accompanied with a concise statement of the proceedings of the day.

The Society was complimented by a delegation from the Essex Agricultural Society and from the Windham County Society, in Connecticut. Many distinguished strangers honoured us with their company. Among them, were observed Commodores Rogers and Chauncey, and Capt. Biddle, of the Navy, the Hon. Messrs. LLOYD and QUINCY, of Boston, and JOHN HARE POWELL, Esq. the celebrated agriculturalist, of Philadelphia.

The thanks of the Society are due to many gentlemen who volunteered their services in carrying into operation the previous arrangements.—The gentlemen who acted as Marshals deserved great credit for the promptness and efficiency with which they discharged their duty. The following gentlemen executed this responsible and arduous trust:—Col. Joseph Davis, Col. Samuel Damon, Col. Ariel Bragg, Col. Moses Grout, and Maj. Nathan Heard, jun.

We reflect upon the proceedings of the day with much satisfaction; and we ardently hope that each succeeding Anniversary will exhibit the most unequivocal evidence, that this extensive and populous County is advancing rapidly in those improvements which are the strength, and ornament, and glory of a community.

Oct. 2. 1822.

From the Windsor (Vt.) Journal of Oct. 7.

The second annual Cattle Show and Exhibition of Domestic Manufactures, of the Windsor County Agricultural Society, was holden at Windsor on Tuesday last. The weather was favorable, and the novelty of the occasion (in these parts) together with the lively interest which is felt by every class of our citizens for the

prosperity of Agriculture and Manufactures, brought together, at an early hour, an immense concourse of people. At half past ten o'clock, A. M. the procession was formed and escorted to the Meeting House, where an appropriate and well received Address was delivered by TITUS HUTCHINSON, Esq. a copy of which has been requested for publication, by the Society. The Society then adjourned, to meet at 4, P. M. at which time the several examining committees reported the award of premiums, as follows:

To John Davis, of Springfield, for the best yoke of working oxen \$12
 To David Trumbull, of Hartford, for the best milch cow 8
 To Herschel Davis, of Springfield, for the best bull 10
 To William Jarvis, of Weathersfield, for the best bull calf 7
 To John Davis, of Springfield, for the best heifer calf 5
 To Zebina Curtis, of Windsor, for the best boar 5
 To William Jarvis, of Weathersfield, for the best ram 6
 To Zebina Curtis, of Windsor, for the second best 4
 To Henry White, of Windsor, for the best yoke of working three years old steers 6
 To Daniel Bowen, of Weathersfield, for 2d best 4
 To William Jarvis, of Weathersfield, for the best breeding mare with her colt 8
 To Simon Smith, of Hartford, for the best stud horse 8
 To Timothy Curtis, of Windsor, for the best saddle horse 5
 To Henry White, of Windsor, for the best sow and six pigs 5
 To Jones & Gregory, of Windsor, for the best ten sides of upper leather, and best ten calf skins 8
 To Joseph Parker, of Woodstock, for the best pair of boots 2
 To William Jarvis, of Weathersfield, for the best plough 4
 To Jonathan Williams, of Springfield, for the best piece of factory woollen cloth 7
 To the same for second best 5
 To Philemon Hazen, of Hartford, for the best crop of spring wheat raised on one acre of land 7
 To Zebina Curtis, of Windsor, for the best crop of corn raised on one acre of land 7
 To Abel Barron, of Hartford, for the second best 5
 To Luther Spencer, of Weathersfield, for the best piece of household manufactured cloth 5
 To Charles McKensie, of Hartland, for 2d best do. 3
 To Oliver Pierce, of Weathersfield, for the best piece of flannel 5
 To Reuben Damon, of Hartford, for second best 3
 To Moses Pollard, of Plymouth, for best 1000 lbs. of cheese 6

The premium for the best 500 lbs. of cheese was awarded to Mrs. Luther Taft, of Woodstock, but could not be paid at present on account of the want of evidence required by the regulations.

The quantity of corn raised on one acre and five rods of land by Gen. Curtis, was 113 bushels, 31 quarts, and one pint.

The quantity raised on one acre by Abel Barron, Esq. was 104 bushels and 11 quarts.

Besides the animals on which premiums were awarded, there were a great number of thrifty cattle, horses, and swine exhibited, which indicated that the object of the Society had been already greatly obtained—that of exciting laudable emulation. Among the number of these which deserve notice, was a cow, belonging to Mr. William Johannot, of Windsor, from which one hundred and ninety-three pounds and ten ounces of butter was made between the 29th of April and 27th of September last, averaging 9 lbs. a week. The working oxen, cows, &c. of Mr. William Jarvis, not entered for premiums, were very much admired.

There were also exhibited, a variety of ingenious and useful manufactures, for which no premiums were offered, but which were reported by the examining committee to be worthy of premiums from the Society.

Of the premiums awarded, the following were generously returned into the funds of the Society—by William Jarvis, Esq. \$19.00; Gen. Zebina Curtis, \$8.00; Mr. Timot. Curtis, \$5.00.

The following gentlemen were elected officers of the Society for the year ensuing—

Zebina Curtis, *President*.—Jabez Proctor, Titus Hutchinson, Abel Barron, *Vice Presidents*.—Norman Williams, *Secretary*.—Job Lyman, *Treasurer*.—John A. Pratt, *Collector*.

From the American (Vermont) Repository.

The Chittenden County Society for promoting Agriculture and Domestic Manufactures, held its fourth annual meeting at Burlington, the 24th of September.

At an early hour in the morning, a very considerable number of fine cattle, &c. were on the ground designated for the exhibition, and by 10 o'clock the committees entered on the duties severally assigned them. The day was exceedingly fine, and the honest pride and exulting satisfaction that marked the countenances of every individual, seemed to distinguish this anniversary from any previous one, and to have entitled it *peculiarly* to the distinctive and appropriate appellation of the "Farmers' Holiday."—The number of cattle, colts, sheep and swine, was unusually large, and afforded unequivocal evidence of the increasing attention which has recently been paid to the improvement of the breed of these animals. The committees were engaged till about 1 o'clock, in the performance of their respective duties, when they closed their examinations and reported thereon. The Society then moved in procession under the direction of the Marshals of the day, to the Brick Church, where an appropriate prayer was offered by President Haskell, of the University. The Society was then favoured with an address from Elkanah Watson, Esq. of Albany, N. Y. the projector and founder of the celebrated Agricultural Society in Berkshire, Mass. the first Society established upon the plan now universally adopted by the numerous societies throughout the country.

From the Northampton Gazette.

Cattle Show and Fair.—The Hampshire, Franklin and Hampden Agricultural Society will hold their annual Cattle Show, Plowing Match, and Exhibition of Manufactures in this town, on the 23d and 24th inst. The Address, we understand, will be delivered by John Mills, Esq. of Southwick. It is confidently expected that the Farmers and Mechanics will make vigorous efforts to render this Cattle Show and Fair honorable to themselves and the Society, and a powerful auxiliary to improvements in Agriculture, Domestic Manufactures, and the Mechanic Arts. Let not the ladies be deterred by sentiments of false modesty, from exhibiting their various articles of Household Manufacture.—The products of female industry and ingenuity, heretofore exhibited, have done them much honour; and upon their exertions will depend much of the interest and utility of the annual show

From the New York Statesman.

Explanatory.—In the article headed *Horticulture*, in last evening's Statesman, [see last page] it has been supposed we were not explicit in stating, that the second crop of Mr. Parker's corn was raised from the seed of the first crop, which was the fact, and a fact too, which is believed to be unparalleled in the agricultural history of this state. Mr. Parker has planted seed from the second crop, for the purpose of seeing what advances the third growth will make.

From the Wilmington Watchman.

On the 5th of May last, I sowed half a bushel of Millet seed on an acre and one quarter of ground, which I had manured for the purpose. About the 23th July following, when the heads were yellow and the stalks and blades green, I had it cut. It produced three tons of hay which my horses eat with as much avidity as they would the best upland. It yielded 30 1-2 bushels of clean seed, exclusive of what was left in the sheaves, weighing 49 1-2 pounds per bushel. When manufactured into flour it makes a cake equally palatable as buckwheat, and I believe more wholesome. By not mowing it till the seed are ripe all the advantages derivable from the seed will accrue to the farmer, and the hay will be equally good if not better than if cut earlier. I think I sowed mine rather too thin. I am informed, and from the experiment I made, I believe correctly, that it will produce more and better of both hay and grain if three pecks or one bushel of seed be sown to the acre, according to the quantity or strength of the ground.

"This crop has a great advantage over most others. It is sown and gathered at a time when it does not interfere with other work. My crop was cradled, shocked and bound the same as wheat. It remained about five days in shock, and was thrashed in one day by two men, as it was hauled into the barn, so easy is it to thrash."

WILLIAM WARNER.

Wilmington, Sept. 11, 1822.

From Niles' Register.

Support of the Poor.—When last week we spoke of the richly endowed hospitals and other establishments for the relief of the poor in England, we reprobated those systems that *made paupers to fill them*; believing it far better to provide employment by which persons may maintain themselves in independence and comfort than to furnish means for affording them a beggarly and mean subsistence. A letter from a gentleman resident at or near Williamsburg, O. addressed to the editor, says—"perhaps it may be gratifying to you to know that there is one 'sequestered nook' where the people are not oppressed with poor taxes. We have no pretensions to wealth here; but, for the eighteen years that I have resided in this place, I have not paid or been charged one cent for the support of the poor. It is provided by the laws of our state, that assessments shall be made in the various townships, if necessary, for maintaining the poor—and our township, at the last census, contained eleven hundred and seventy-seven persons." There are not any paupers.

Mrs. Judson, wife of a Missionary, has arrived at Philadelphia from India.

MASSACHUSETTS AGRICULTURAL REPOSITORY AND JOURNAL, FOR JUNE.

(Continued from p. 63.)

A letter to the Corresponding Secretary, on the subject of Fruit Trees, with the signature, "A Norfolk Gardener," contains the following judicious observations:

"The health, habits and fruitfulness of a tree depend upon the habits it receives in the nursery.

First. The health of the tree depends in part on the soil of the nursery, which should be free from manure, and as nearly a good virgin soil as possible. This soil will give sufficient nourishment to the plant without forcing it into luxuriance; and when it is transplanted from the nursery it will not be checked in its growth if the soil into which it is put has never been manured. Young trees are more healthy by being put into pure natural earth than if manured; and when age and decay come upon them they will feel the benefit of this stimulus, if applied, with more effect.

One of the principal causes of ill health or canker in young trees taken from nurseries is, that the nursery men seldom take the trouble to cut off the wood above the bud close to its shoulder, leaving a smooth and sloping surface. If they were to do this the wound would heal the first season; but they usually leave a small piece from which the top has been sliced off without care or reflection half an inch above the shoulder of the shoot or bud, and of course beyond the reach of the sap which issues from it, and from the edge of the live bark to cover the cut. This piece of wood dies, and it will soon communicate its disease to the sound bark and wood, until the evil is beyond the reach of the knife.

Second. The habits of a tree depend in a great measure on the quality of the scion or bud which is put into it, and on the direction given to its branches in the training and pruning them.

The scion or bud should never be taken from a tree that is unhealthy, or that is not in bearing; and the strong and luxuriant shoots should always be rejected. It is even better never to take them from a tree that is very luxuriant in its growth.

If it be an apple, or pear tree, select your scions from the end, or near the end of the fruit bearing branches. The buds of the shoot should be plump, full and healthy. The middling sized scions are the best. The young tree will assume the character of the scion which is inserted into it, and will grow moderately or otherwise; fruitfully or barren, according to the judgment used in selecting the scions and pruning its branches.

If it be a peach that you are to bud, take the fruit bearing shoots of a moderate size with double and triple buds. These will put out blossoms in the spring, which may be rubbed off when the wood bud has opened, and the second year your tree will show fruit. Whereas trees grafted or budded from strong glutinous shoots grow vigorously for many years without giving the cultivator any returns for his labour. I have trees, both pears and peaches, in my garden, which were taken from a public nursery more than ten years ago, and which have always been growing with rapidity, and in apparent good health, but which never produced me

any fruit; and I have others which I have budded myself, which have been constantly in bearing from the second summer after the insertion of the bud or graft. This variance I attribute entirely to the difference in the qualities of the scions, or buds.

Third. There is no doubt that the quality of the soil contributes also very powerfully to the fructification of fruit trees. Different fruits require different soils to make them perfect in their kind; as the Doyenne, or Saint Michael pear produces best in a gravelly soil, while the brown Beurre requires a more nutritious earth and a more sheltered situation to bring it to perfection. But as a general rule, it is better for young trees to be placed in a good, but not a rich soil; as the fructification will be retarded by too rapid a growth; but the fecundity of the tree may be effectually secured by a judicious choice of scions, and a healthy virgin soil that is light and warm."

An article which is headed *Bad Winter Keeping of Cows*, by John Prince, Esq. of Roxbury, contains matter well deserving the attention of the practical farmer. Mr. P. observes that,

"The too general practice of feeding cows in the winter with only meadow hay, (which has less nourishment than good straw) because they cannot sell it, and have plenty of good English hay which goes to market, is I think very bad policy. If meadow hay must be used in part, let it be salted when put in the barn, and fed in racks, in the yard by day, and good hay, with vegetables of almost any kind in the barn, night and morning, and if bran or oil cake meal can be procured, both of which generally may be had at reasonable prices, they ought to be freely used, even though the cow should be dry.

"I had myself an instance of the good effect within three years past, having purchased a high priced and very fine cow, in the autumn, which I put out for the winter in a good hands as any farmer in the country, to be fed as his own stock were; the whole summer, after coming home, though in good pasture, she never gave more than five or six quarts at night milking. The next winter she was kept at home, when she was well fed with good hay, and mangel wurtzel, Swedish turnips or carrots, once a day (though dry) and the whole of the next summer she gave from eight to ten quarts at night milking, and has continued ever since, in the summer season to do equally well."

Mr. Prince advises to use meadow hay freely for litter, and to card or curry the animals, by which means he is satisfied that they enjoy better health, and will consume less food, and observes:

"I think it of more importance than is generally believed, that the male, to which the cow is sent, should be of a really good breed, even although the calf is not intended to be raised—the veal will be better, and I believe there is no doubt also, it has some effect on the milk for the next season." He thinks that "most farmers, who now keep 10 or 12 cows in the common way, by selecting *one half* the number of their richest and best milkers, would make more butter than they now do, and there is also no doubt, that the manure of well fed animals is infinitely superior to that from mean-

ly fed ones—and I believe the quantity would be as great as from double the number."

In these sentiments we fully and heartily concur. It was a pithy saying of the Rev. Mr. Packard, (if we mistake not) of Marlborough, Mass. that "were dairies estimated by the *pails of milk* they produce, instead of the *number of cows*, many farmers' wives, instead of asking their husbands to buy another cow, would urge them to *sell two* to enrich their dairy."*

"We often see in large families," continues Mr. Prince, "where only *one* cow is kept, and that *one well fed and attended to*, that she gives an abundance of milk and cream, and also makes six or eight pounds of butter per week. This is not so much owing to the qualities of the cow, as the care and attention of keeping her well fed and regularly and thoroughly milked.

"I really wish our farmers generally, would be prevailed on to raise a greater quantity of vegetables for the use of their stock, than they have been in the habit of doing. Swedish turnips and Mangel Wurtzel (of the true sorts) are very easily raised, and every farmer has land suitable for them, when he might not have suitable soil for Carrots, which I think give the richest milk, but are much more expensive in cultivation. These roots with care, even in pits, out of doors, may be preserved till May and June, and yield generally double the quantity that the same land would yield in potatoes. In deed with me I have usually had more than three times as many bushels per acre, and with I think no more labour. Mangel Wurtzel indeed will by their thinnings and trimmings, if done with care, pay all the labour of the crop, and give a fine evening food for the cows, and is also an excellent food for swine.

A small patch of corn broadcast or in rows, and cut after it gets two and a half or three feet high, will give a fine evening food for cows, by cutting it at about one foot from the ground, it will grow again for another crop."

"The statements of the unsuccessful candidates for premiums, whose crops fell in some degree short of those which obtained premiums, with the account of the culture," are next in order. The Editors of the Journal preface these statements by observing, among other things, that "it is not enough to grant a few premiums, limited by our small pecuniary means. The interests of agriculture require, that we should shew that the premium crops were not extraordinary, were easily attainable by all, were in fact almost equalled by others."

We have then a letter from Mr. Samuel Wright, Jr. of Westford, Mass. to the Chairman of the Committee on Agricultural productions, giving an account of his method of culture, by which he raised 72 bushels and 5 quarts of Indian Corn on an acre.

"The ground was a piece which had been laid down and mown six or seven years. I ploughed it late in the fall of 1819, and in the spring of 1820 I planted it with corn and manured it only in the hill with compost, from which I had a decent crop of corn. Early in

* Mass. Agricultural Repository, vol. v, p. 71.

he spring of 1821, I ploughed the ground coarse-ly, and spread eighteen or twenty cart loads of coarse manure, then harrowed, and then ploughed the ground very fine, and on the 20th of May planted it in rows, the kernels about nine inches apart, and the same quantity of manure in the rows as I spread, which was a composition of horse, hog and door manure. The first and third time of hoeing, I hoed without ploughing; the second time I ploughed and took from the stalk all the suckers which came out next to the ground. The corn growing exceedingly rapid I followed cutting all the stalks which did not set for ears, and those which grew smutty. The corn was a twelve rowed kind, which I have raised a number of years, and more forward than my neighbours generally, and I know of no improvement which I could make except in the furrowing. This season I drew my plough but one time in a row, the ground being stoney, and putting the corn on top of the manure made the row too high; whereas drawing it twice would have made more room for the manure, and laid the roots lower."

Mr. John Dwinell, of Salem, Mass. gives the following statement of his mode of raising a large crop of Carrots.

"The land is situated in Salem. county of Essex; has been broken up about four years; was planted the past year with onions, beets and carrots, ten loads of mixed muckle bed, rotted potatoe tops and barn manure being put on; the soil black and heavy.

The present year eight loads of privy manure, for one yoke of oxen, were put on, spread in four hours, and sown with about one pound of seed: 19th of April the lot was ploughed; 11th May, one day sowing; 11th and 12th June, four days weeding; 9th July, two days weeding; 16th and 17th July, forking; and from 26th October, twelve days labour in digging, measuring, weighing, &c. in all twenty-two days and four hours labour.

The quantity produced on the acre was five hundred and twenty-eight bushels, which at forty-seven bushels, (being very well cleaned) to the ton, gave 11 ton, 4 cwt. 2 qr. 20 lb."

(TO BE CONTINUED.)

FOR THE NEW ENGLAND FARMER.

This is the season when farmers are gathering in their produce and estimating the quantities. They may readily measure their grain by the bushel, and weigh their flax by the pound; but to ascertain the number of their gallons of cider they will find attended with difficulty.

Some years ago I undertook to write a new treatise of arithmetic, better adapted to the capacity of the learner and agricultural business than any heretofore published; in the composing of which I did not take any thing for granted, but demonstrated and proved every rule that I laid down.

In gauging I found that all the rules that any authors had laid down were either very erroneous, or required such a tedious calculation with a vast number of figures as to be liable to error and that their diagonal and gauging rods were at best but a random way of guessing at the contents of casks of different proportions.

I tried various ways to raise a theorem more simple, plain and correct than any that I could

find published, and after nearly despairing of finding any better or more short than the rules laid down by the learned and ingenious James Ferguson, I accidentally hit on the following:

- 1st. Multiply the mean diameter by its li.
- 2d. Multiply the product by the length,
- 3d. Multiply that product by 31,
- 4th. Strike off four decimal points and you have the true contents in gallons and decimal parts of gallons.

The excellence of this rule is, it avoids the tedious process of any long division, and does not require one fourth part of the number of figures as the shortest rule laid down by James Ferguson, and it is equally correct in casks of any proportion.

The dimensions should be exactly taken with a scale that has the inches divided into tenths, and the work will stand as follows: Suppose the cask, Bung diameter, 28 inches.

Head do.	20	
Length,	32	2) 48
		24 mean dia.
		24
		96
		48
		576
Multiply by length,	32	
		1152
		1728
		18132
Multiply by	34	
		73728
		55296
		62,6688

The true content is 62 gallons and , 3688 decimal parts of another gallon.

I could readily give a demonstration of this theorem on the principles of *Euclid*, but leave that as an exercise for the students of mathematics, perhaps if they do not immediately hit on this theorem, they may some other.

This concise rule makes the small allowance that James Ferguson recommended for the spheroidal figure of casks, and if it deviates, it gives a little too much by the inside of the casks not being geometrically round.

If there is any readier way to find the contents of a cask, I believe I have it in a treatise I have written on a new science, that I call *Semi Geometry*, and which teaches how to project almost every thing necessary in country business, with a plain scale of equal parts, and pair of dividers, without any calculations by numbers. I carried it so far as to project extracting the cube root and gauging casks, and finding their ullage.

To find the contents of a cask by *semi geometry* is a very handsome projection, but the figure cannot be intelligibly described in a newspaper, without a large plate—yet, to such as are well versed in *Euclid* I may render myself intelligible, for to such if they are expert with a scale and dividers the contents of a cask, without any calculation, may be projected into a parallelogram, of equal contents superficial measure.

That for a large cask, would be extensive, and may be reduced, although 231, the cubic inches in a gallon, is an uncouth number to divide—it will divide by 3 and 77 only; then suppose the parallelogram is projected for 3 inches deep, we have 77 to divide again, that will divide by 7 and 11 only, then project the reduced parallelogram to one of equal content 11 wide, then step off the gallons by 7.

Semi Geometry is a science that all farmers ought to learn, in order to be ready to lay out any kind of farmers or mechanical business.

In my treatise of arithmetic I taught decimals with whole numbers from the first numeration table, in order to suit the currency of the United States. I taught that there was but simply the nine numbers in nature, that any thing further than nine was but repetition, according to place in the numeration table. That nine was the *Crown Number*, and would prove any calculation within the four rules in whole numbers, and taught how to prove them, as also if there was an error in multiplication to shew whether it was made in multiplying or adding, and if in long division whether in multiplying or subtracting.

When I came to treat of interest, I disliked very much any rules that I could find published for calculating interest for days or broken time, as the work was too tedious and too much lost in little fractional remainders to be correct. I tried a variety of ways to form some better and more exact rule that would not require so many figures—until I discovered *nine proportionate Logarithms* (and there is no more in nature) that will shew the interest of any broken sum of dollars and cents for any broken time or number of days, or at any rate per cent—and bring out the whole in one sum to the ten thousandth part of a cent, with less figuring than any other mode, and without any division, which I believe the greatest of my discoveries.

I shewed them at several of the banks that I could calculate interest quicker and more correct than any clerks they had—but they spurned at such instruction. I then tried to sell my *copy right* to several printers—they would not buy it because they said it was not like *Dilworths* and other treatises. I told them if it was like other treatises there would be no need for them to buy it—and that if people would be such slaves to custom as not to look at any thing new, they never would advance in improvement.

At this advanced period of life I believe that my labours for the benefit of the public must die with me, except some few ideas that may be retailed in newspapers.

SAMUEL PRESTON

Stockport, Pa. Sept. 19, 1822.

Camden, (N. J.) September 17.

We have seen a specimen of Cotton of a strong and silky texture, raised in a garden of a gentleman in Camden; most of the pods on the stalks are likely to come to maturity, although the seeds were planted quite late in the spring. We understand that the cotton has been pronounced by a gentleman from Louisiana, equal to that which grows in the southern States.—Who knows but that the cultivation of cotton, on particular species of soil in West Jersey, may at some future period, become an object worth the attention of the farmer!!

N. E. FARMER.

BOSTON:—SATURDAY, OCT. 12, 1852.

BRIGHTON FAIR AND CATTLE SHOW.

The annual exhibition of Cattle and Manufactures was holden at Brighton on the 9th and 10th inst. The fair was attended by a large concourse of citizens from Massachusetts and the adjoining States, including some from the southern section of the Union. Fine animals, fine manufactures, fine vegetables, rare, curious and useful machines, the best products of the soil, and the best results of mechanical ingenuity, proofs of industry excited by emulation and guided by skill, were exhibited in profusion. Detailed accounts of all that was worthy of notice would be too voluminous for insertion, and are rendered unnecessary at this time, as we propose to publish the official reports of the several committees, as soon as received.

At one o'clock, of the first day, the Society went in procession to the Meeting House. A prayer by the Rev. Dr. Foster, and an Address by the Hon. TIMOTHY PICKERING, composed the exercises at that place. Mr. Pickering's Address was plain, practical, and replete with valuable information. The subjects treated of (such as the theory of vegetation, the food of plants, the uses of lime and the mode of its operation, &c.) were some of them abstruse, but rendered as perspicuous as possible by the venerable Orator, who adapted his style to the unlettered as well as to the learned hearer, by giving the common as well as the scientific name to such substances and ideas as could not be supposed to be familiar to all classes of his audience.

On the second day of the Exhibition, at 4 o'clock, P.M. the Premiums were declared in the Meeting House. The first premium of \$10 for fat oxen was awarded to Mr. Oliver Starr, of Deerfield—this animal was six years old and weighed 2333 lbs.—2d premium \$30. to Lewis Barnard, of Worcester, animal six years old, weighing 2256 lbs. To Maj. Jaques, of Charlestown, for his Bull, 1st premium, \$30—2d do. to Mr. Coolidge, of Watertown. To the owner of a Cow from Salem \$30. Several other fine animals were spoken of as richly deserving a premium. For Heifers, the 1st premium was awarded to Henry Rice, of Marlborough, for one two years old, with a calf six weeks old, weighing 88 1-4 lbs.—2d do. to Samuel Brooks, of Brighton.

For the best Boar, to Joseph Rice, \$10. Mr. Sparks, of Watertown, 2d best, \$5. For four Pigs, to Luke Fiske, \$5. To A. Dow \$5. For a Merino Ram, the first premium was awarded to Gorham Parsons, Esq.—2d to Gen. Austin.

Mr. S. Jaques, of Leicester, received a premium of \$50, for a breed of long woolled Sheep, 6 ewes and 1 lamb. A Ram and two Ewes, remarkable for heavy fleece, fine wool, &c. were

exhibited by Hon. T. H. Perkins, though not for premium. The committee, however, are of opinion, that he ought to be presented with the Society's gold medal.

Twelve yoke of Working Cattle were entered. The 1st premium, \$30, was given to Luther Whiting, of Sutton—2d do. \$25, to Peter Dudley, of Sutton. Several other premiums were divided among people from that town.

Among the inventions was a cast iron roller, by Aaron Willard. A Vertical Family Spinner, which has been for some time in use in Rhode Island, was well spoken of for its labor saving qualities.

Of Manufactures, the 1st premium of \$30, for Broadcloths, was awarded to James Shepherd & Co. of Northampton—2d do. \$20, to Wolcott Woollen Manufactory—2d do. on Cassimeres to Shepherd & Co. To George Johnson, Salem, for a quantity of American Duck, \$10.

There were only three premiums awarded at the Ploughing Match, viz. to J. Cook, of Brookline, 1st premium \$20—to J. Curtis, Roxbury, 2d do. \$12—To Stedman Williams, Roxbury, \$8. The work was done in from 22 to 36 minutes, making 18 to 20 furrows.

The above is but a hasty sketch of the proceedings on this occasion, and is partly the result of personal observation, and in part abridged from the Boston Daily Advertiser. We hope it will allay, if not gratify, public curiosity, till the official account is received.

ON SAVING AND MAKING THE MOST OF MANURE.

(Continued from page 63.)

In our preceding observations under this head, we took a concise view of the controversy existing among agricultural writers as well as practical farmers relative to long and short, fermented and unfermented manure, and mentioned the names and opinions of some eminent writers, who had taken opposite sides of the question. We likewise attempted to shew that the disputants were not, in our opinion, exactly right, nor altogether wrong—That in certain soils and for certain crops, long manure, which had undergone but a slight and incipient fermentation, was to be preferred—but when used for white crops, and indeed any crops which cannot conveniently be hoed or weeded, or probably when applied to soils containing acids or some principles which would prevent fermentation, and stop the progress of putrescence and dissolution, it must be well rotted.

Rotting manure, however, in a barn-yard or in any situation in which its volatile and liquid products escape into the atmosphere, or soak into ground not designed to support vegetation, is very slovenly and wasteful, and always to be avoided if possible. The steam, effluvia, or gas which is suffered to escape from fermenting manure, is not only almost altogether lost to useful vegetation, but, what is still worse, fills the atmosphere with particles injurious to health, and often destructive to life. The evaporations from a manure yard rob the farmer of a part of his substance, starve his crops, and it is well if they do not moreover poison him and his family by their contaminating influence. Some farmers' barn-yards, hog-pens, and other receptacles of manure are very offensive, and if they do not generate typhus fever in its worst form, which we fear

is frequently the case, they at least cause a degree of languor and debility which embitters existence, and in a great measure disqualifies for any of the useful purposes of life. It is a fact that those exhalations, so injurious to animal life, are the essence of vegetable life, and the volatile substances, which offend our senses and injure our health, if arrested in their transit by the hand of skilful industry, may be so modified in the great laboratory of nature as to greet us in the fragrance of a flower, regale us in the plum or nectarine, or furnish the stamina of life in substantial viands, composed of materials drawn from the butchers' shambles.

If we are correct in these premises, an important axiom may be deduced, viz. *No putrefactive process ought to be suffered to proceed on a farmers' premises without his adopting some mode to save, as far as possible, the gaseous products of such putrescence.* These gaseous products constitute important elements of vegetable food, and a farmer may as well permit his cattle to stray from his stall, or his swine from his sty, without a possibility of reclaiming them, as suffer the principles of fertility, expelled by fermentation and putrefaction, to escape into the atmosphere for the purpose of poisoning the air, instead of feeding his plants. It is very easy to arrest these particles. A quantity of earth applied to, or thrown over the matter in which fermentation is going on, will check its violence, and secure its gaseous products, which will be imbibed by the soil and afterwards yielded to plants in such proportion as the wants of vegetation may require.

"Fermentation," says an able writer, "that great destroyer of all organic conformation, is not to be feared by the farmer, if it be conducted and carried on in the presence of earth, which fixes and secures the gases as fast as they are liberated. Even the degree of the process is a matter of less consequence; because if the elementary principles are in keeping, and reserved for future usefulness, it is immaterial whether this has happened by a new absorption, or by still holding their original and unchanged form. In his composite hill [compost heap] the whole animal or vegetable structure may be dissolved, and leave behind no trace of existence, without the least waste of the principles of fertility; because the ingredients superadded to the dung have become surcharged with them, or to speak philosophically, fully saturated. We may go farther and state, that complete decomposition is desirable in this case, which is so much to be avoided in the farm yard; because putrescent matter can only become vegetable food by its resolution into primary parts, and if this be effected by any preparatory step, the young crop receives the full and instantaneous benefit. The compost manure is carried to the field ready to give out its richness on the very first call, and to supply the nascent radicle [young root] with a copious share of nourishment.

"The putrefactive process may be carried on in the presence of pure earth only, or of earth intermingled with fibrous roots, or lastly, in the presence of peat, which is an assemblage of inert vegetable matter; and compost dunghills may be formed according to this threefold method.

"The simplest of all composts is a mixture of barn yard dung, and surface mould taken from a field under regular culture. The proportions between the ingredients are fixed by no determinate laws, and consequently great liberty is allowable to the operator. I have known some instances where two cart loads of dung were used for one of earth; others, where they were blended in equal quantities; and it is not infrequent to compound two of earth with one of dung. In fact, such is the uncertainty in the composition, that almost every farmer adopts a mode peculiar to himself, and with equal success. No man need therefore follow implicitly the rules which are laid down in this department of rural economy, but may vary and multiply his experiments, according to the suggestions of fancy or the dictates of convenience. If we slightly glance at the principle, we shall see the cause of this seemingly endless variety in the combinations of the ingredients. The

THE NEW ENGLAND FARMER,

PUBLISHED BY THOMAS W. SHEPARD, ROGERS' BUILDING, CONGRESS STREET, BOSTON.

SEVERAL numbers of a Newspaper, with the above title, have been published in Boston, and have met the approbation of intelligent Agriculturists, and an enlightened public. The following remarks relative to this publication, are the result of the unbiassed and disinterested deliberations of highly respectable and very competent judges, whose names, and the observations to which their signatures are attached, must render farther recommendations superfluous.

NEW ENGLAND FARMER.—Published by Thomas W. Shepard.

The opinion of the subscribers having been requested in favor of this publication, with the avowed and very proper wish, on the part of the publisher, that it might tend to the increased circulation of his Journal, (the first, avowedly devoted to the interests of agriculture in New England,) we cheerfully afford our testimony, as far as it may be of any value to him. Though the American public, when compared with that of other nations, may be considered a thinking and reading one, yet from various causes, which it cannot be necessary to state, much the greater part of its reading is confined to, and its information obtained through daily, weekly and other periodical journals. In a country, in which the Elective power as to almost all offices, is enjoyed and exercised by the great mass of the people, it is natural, that politics, including the national, state, county and town interests and concerns, should occupy much the largest share of our public journals—next to these, commerce and manufactures must of necessity hold a high rank. These require so much more constant and more accurate information—so much in those branches depends on political, commercial and agricultural events abroad—so much on the state of foreign markets, on losses and disasters at sea, that it is not surprising that nineteen twentieths of all our newspapers are occupied either with politics or commercial news. So much is this the case, that it was doubted for a long time whether an Agricultural Newspaper could be supported—but the success of the American Farmer, printed at Baltimore, by John S. Skinner, Esq. and the Plough Boy, at Albany, by Solomon Southwick, Esq. has proved that there is a sufficient degree of zeal and intelligence and desire of knowledge among the cultivators of the soil to sustain a few purely agricultural papers. If one is to be added to the two, which now exist, among the several thousand Newspapers now printed in the United States, it would seem that New England is its natural and most proper situation, and Boston as conveniently placed for its publication and correspondence as any place in New England. We hope we have as many thinking and reading farmers in the Six New England States, not only as any other portion of this country, but as any equal portion of the cultivated world can afford or furnish.

It seems to be absurd, that farmers should subscribe for papers devoted exclusively to questions in which they have only a remote interest, and should *decline* giving their aid to one entirely devoted to their instruction, amusement, and to the record of their improvements, doubts, queries, discoveries and speculations. The paper now commenced has every thing to recommend it as far as we have had an opportunity to judge. Mr. Shepard is well known as an editor of a valuable paper at Northampton. That he has all the professional skill, and the requisite liberality in the execution of his work, is manifest by the numbers already published. They are neatly executed on good paper and with a fine type, with great care and accuracy, far above, in these respects, (we may say, with out offence, we hope,) any other like publication. His present assistant, THOMAS G. FESSENDEN, Esq. is a man of reading and talents, and has paid great, and for our country, almost unexampled attention to agricultural subjects. His mind is philosophical, and his attention is undistracted by other pursuits. His life has been principally devoted to such subjects. The numbers as yet issued are respectable, as much so as could be expected, before the public at large had taken an interest in the work. We hope that it will succeed, but that must wholly depend on the aid which the intelligent Divines, Lawyers, Physicians, and practical Farmers in the country will afford it. That aid must consist not only in taking it and paying their subscriptions—that to be sure, is its *necessary food*, without which it must starve—but in favoring it by communicating their thoughts, experiments, objections to existing practices, or to new projected improvements. It should be remembered, that this is a mere Newspaper, and therefore, that a man who would not write a book in his own name, or an article for the Massachusetts Agricultural Repository, need have no scruple in writing for this.

The New England Farmer is published weekly, on Saturdays. Each No. contains 8 quarto pages, printed on a sheet of good quality, with an entire new type. The price is \$2.50 per annum, *in advance*, or \$3.00 at the close of the year.

Each volume will comprise 52 numbers, and the present volume commenced the first Saturday in August. A title-page, and a correct and copious index will be given at the end of each year.

Persons who will procure seven subscribers and become responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

Congress-street, Boston, Oct. 1822.

✂ Editors of papers with whom we exchange, by giving the above an insertion, will confer a favor which we shall be happy to reciprocate when an opportunity offers.

only use of intermixing the soil with the dung is to imbibe the gaseous elements of vegetable life, and hinder their dissipation. If there be much soil, these elements will be diffused through it with less density and compression; if little, it will be more abundantly saturated, and enriched with the nutritive vapors. The only error, into which the farmer can run, is to supply such an inconsiderable quantity as will be incapable of imbuing the elastic and volatile particles, and thus by his own mismanagement, occasion a waste of the vegetable element. One cart load of soil to two of stable dung is the least proportion which he should ever attempt to combine, and perhaps if the two were mixed equally, it would be compensated for the additional labour and expense."

"Simple earth, although excellent for bottoming and strewing over the pit dug near the barn, is of all materials the most unprofitable in compost dunghills. A matted sward thickly entangled with roots, or mud ragged from the bottom of bogs or ditches, and replete with aquatic plants, are clearly preferable on this account, that, besides bringing earth to the composition, they supply a large proportion of vegetable matter. Whenever the soil must be carted to the heap, it is better to lay out the expense in transporting these enriching materials; because they will not only equally absorb and retain the evaporating gases, but greatly augment the quantum of manure."

The path proper for a farmer to pursue in order to make the most of his manure and preserve his own health and that of his family is plain and straight as a rampe. Whenever putrid fermentation is going on, in any part of his premises, and consuming his substance by a slow but wasteful combustion, let him apply earth, peat, or some earthy substance, in quantities sufficient to attract, imbibe and retain all the effluvia. Health, profit and cleanliness equally require such proceeding. We shall say a word or two upon the latter topic. If a man were to swallow daily, a quantity of filthy matter, or to eat his food impregnated with steams from a manure heap, or from some other strewing and offensive substance, when he might, with a little exertion, avoid such nauseous viands, and substitute something nourishing, palatable, pure and wholesome, we should be apt to set him down for a sort of Hotentot. But, *a man may almost as well take dirt into his stomach, as filthy effluvia into his lungs*—may about as well dine with a crow or a buzzard, sup with a toad "on the vapor of a dung-hill."

* *Letters of Agricola.*

(TO BE CONTINUED.)

✂ We have received an official account of the Essex cattle Show, which did not come to hand till after the close of that subject, which we have extracted from the Salem Gazette, in type. We hope what we have printed will be a satisfactory substitute for the more detailed account.

Meteorological Journal.—Our attentive Waltham correspondent has sent us his Journal for September, which we shall insert on Saturday. Our correspondent notices, as remarkable, "that the 29th of the month as the warmest morning, at sun rise, that has been experienced for two years; and also, that the mornings the 28th, 29th, and 30th, were warmer than any three successive ones for the same period." He adds, "except a few days, the month has been uncommonly warm, pleasant, and dry; and never was known a more favorable time for ripening and securing the various productions of the earth. Reckoning from the commencement of the warm weather, which was the first day of May, we have passed a long and delightful Summer, and been richly blessed in our basket and in our store."

Wednesday's Centinel.

Among the interesting objects exhibited at Brighton on Wednesday, we noticed three sons (by one birth) of Mrs. Willis, wife of Joseph Willis, of West Sudbury, in its state, a soldier of the revolution. Their names are George Washington, John Hancock, and Samuel Adams. They are now 23 months old and weigh 71 lbs. The mother is 48 and her husband 57 years old.—*Pat.*

RURAL LIFE.

Oh, knew we but his happiness; of men
 The happiest he, who far from public rage,
 Drinks the pure pleasures of the *rural life*.
 Sure peace is his; a solid life estranged
 To disappointment, and fallacious hope;
 Rich in content; in Nature's bounty rich.
 In herbs and fruits; whatever greets the spring.
 When heaven descends in showers; or lends the lough,
 When summer riddens, and when autumn beams.
 Here too dwell simple truth; plain innocence;
 Unsullied beauty; sound unbroken youth,
 Patient of labor, with a little pleas'd;
 Health ever blooming; unambitious toil;
 Calm contemplation, with a mind at ease.

From the New-York Statesman.

Horticulture.—Mr. Parker, of the village of Greenwich, has been actively engaged for several seasons, in making experiments for the improvement of horticulture, which has been too long, and too much neglected in this country.—It is almost incredible what quantities of vegetables may be raised in a common kitchen garden, by proper cultivation. On a soil not apparently remarkable for its fertility, Mr. Parker has now ripening a second crop of corn, which grew this season, an ear of which has been left at our office, and which is already sufficiently advanced for seed. He has a fine bed of beets now growing, and nearly arrived at maturity, on the same ground, from which he has the present season gathered a crop of onions. Some of his vegetables, such as beets and squashes, are of a monstrous size. But what is still more rare, he has rows of cotton, both Upland and S. Island, now ripe for the harvest, and will probably attend the Agricultural Fair in this county, *clad in a suit of cotton reared by his own hands*. We understand that another wealthy and enterprising citizen intends to appear in a similar dress. A fine boll of Mr. Parker's cotton, resembling in its present appearance a water-lily, and also a stock of rice, which grew in his garden, have been left at our office for the examination of the curious.

From the Boston Statesman.

Wool.—We have often urged our country brethren to the growing of this staple material, and we now call upon them again to double their exertion in producing this necessary article of consumption from their farms. The British government sometime since laid a duty of 6d sterling per lb. on wool, which has caused an influx into this country.

We understand from July to September inclusive, of this year, there have been brought into this port 222,316 lbs. of wool, principally from Russia, Sweden, Lisbon, and Smyrna.

The importance of so employing the industry of our population must be obvious, and the uselessness and impropriety of suffering foreigners to be exhausting the wealth of our country, in cases where we possess so many advantages must be apparent to every mind.

From the Philadelphia National Gazette.

Steam Engine.—Thomas Hatton, an intelligent mechanic of this city, has constructed the model of a steam engine, in which the propelling power is applied, in a manner altogether different from that, in which steam has been

used heretofore, in the movement of machinery. The model consists of a wheel of brass, about six inches in diameter, on the periphery of which the steam is applied in chambers, formed by the wheel and a metal rim which surrounds it.—The steam introduced into these chambers, acts upon blocks of metal or pistons closing the chambers, and makes strokes almost equal in length to the circumference of the wheel. The machinery for inducting and educting the steam is ingenious and well adapted to its object. The advantages proposed by the inventor are simplicity, and economy in the cost of construction, in the consumption of fuel, and in the number of hands necessary to work it. As the motion is rotary, he avoids thereby the necessity of the balance wheel, and the loss of time between the ascent and descent of the pistons. The weight will not exceed half that of an ordinary engine, and it will not occupy more than half the room. The model which is completed has been put in motion with atmospheric air, the wheel moving at the rate of 150 revolutions per minute, under a pressure of one pound per square inch, applied upon a piston not exceeding half an inch in diameter.

SELECTED FOR THE NEW ENGLAND FARMER.

If you rise from table with an appetite, you will not often sit down without one.

The smaller the drink the clearer the head, and the cooler the blood.

Men are now-a-days more careful of the breeds of their horses and horned cattle than of their children, though careless enough of the former. But as to the latter, money works wonders; it conceals all defects, mental and corporeal.

Between a man and his wife nothing ought to rule but love. Authority is for children and servants.

Friendship is a union of spirits, a marriage of hearts. Choose a friend as thou dost a wife, till death separate you.

Some are so foolish as to interrupt and anticipate those who speak, instead of hearing and thinking before they answer. This is uncivil as well as silly.

Equivocation is *half way* to lying, and lying the *whole way* to hell.

It is wise not to *seek* a secret, and honest not to *reveal* one.

He that has more knowledge than judgment is made for another man's use rather than his own.

It is folly to dispute upon many things which are disputable. If you cannot agree, you may consent to disagree, and think differently from your friend without quarrelling with him.

To be very subtle and scrupulous in business is as hurtful as to be over confident and secure.

To hazard much in order to get much, savors more of avarice than of wisdom.

There is no character in society more to be pitied, as well as despised, than the idler. He is not only irksome to himself, but he hinders the industry of others. Bishop Taylor once said to a lady who neglected the education of her son, on the plea that he was too young to be confined to study, "Madam, if you don't fill your son's head with something the devil will."

Happiness ever flies away fastest when most eagerly pursued, and no galley slaves labor harder than those who devote their lives to the pursuits of pleasure.

He who has the character of a crafty and tricking man, is entirely deprived of a principal instrument of business, and will find nothing succeed to his wish.

Though the life of man be short of a hundred years he gives himself as much pains and anxiety as if he were to live a thousand.

The celebrated Dr. Cotton Mather, as a precaution against the calamity of tedious visitors, wrote over the door of his study in large letters, *BE SHORT*.

From Relf's Philadelphia Gazette.

THE SALUTING BONNET.

Mr. Relf—I can give no better name than the above to some of the fashionable Leghorns which are now worn by the ladies. The front brim is so constructed and protruded, that the motion of the lady's walk keeps it in a perpetual *nodding* action; and I defy any person, with the same eye-sight I possess to ascertain across the street, whether the ladies mean that you should *touch your hat* in return. I have committed several mistakes in this way; and have afterwards found, to my no small chagrin, that it was not the lady, but the lady's *bonnet*, that was so familiarly *nodding* to me across the street. It was only yesterday morning as I was coming down Chesnut street I was thus *nodded* to by three ladies on the other side. It was so very familiar, that I could not with any pretensions to gallantry avoid crossing, when lo! to my utter confusion the ladies were perfect strangers to me!—Asking pardon, I made a clumsy congee, and proceeded on my walk. This head attire might lead to some unpleasant effects, or misunderstandings. Yours, *A Middle Aged Beau*.

A CLINCHER.—This term is frequently used, but its origin is not generally known. It is thus given by an English magazine. Two journey-men mechanics were one day contending for superiority in the art of invention, and at length laid a wager which of them could coin the greatest lie. When the stakes were deposited, he that was to begin declared that one moon-light night he threw a ten-penny nail with such force that it went quite through the body of the lunar orb, which was then at its full. "That's true," said his opponent, "for I was on the other side at the very moment, and with my claw hammer I clinched the nail." The last fellow was adjudged the prize, and from that time every outrageous falsehood has been termed a clincher.

NEW PEDESTRIANISM.—An idle disorderly fellow at an inn, having proposed to walk for a wager, "you had better," said the landlord "walk about your business."

TURKISH LOVE.—A young man desperately in love with a girl of Stanchio, early sought to marry her, but his proposals were rejected. In consequence, he destroyed himself by poison.—The Turkish police arrested the father of the obdurate fair, and tried him for culpable homicide. If the accused (argued they with becoming gravity) had not had a daughter, the deceased would not have fallen in love, consequently he would not have been disappointed, consequently he would not have swallowed poison consequently he would not have died; but *h* (the accused) had a daughter, and the deceased had fallen in love, &c. Upon all these counts *h* was called upon to pay the price of the young man's life; and this being fixed at eighty piastres, was accordingly exacted.

It was said that the pope advised Petrarch to marry Laura—but that the poet refused because he feared that the familiarity of marriage would extinguish his passion. A blunt person on reading the anecdote observed, "there is a fool who won't eat his dinner, lest he should lose his appetite."

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.00 per ann. in advance, or \$6.00 at the end of the year.

Vol. I.

BOSTON, SATURDAY, OCTOBER 19, 1822.

No. 12.

At a regular meeting of the Society of Middlesex Husbandmen and Manufacturers, holden at Darrach's Hotel, in Concord, on the 3d day of Oct. A. D. 1822, VOTED—

That DAVID LAWRENCE, JOHN KEYTS and NATHAN BROOKS, Esqrs. be a Committee to present the thanks of the Society to THOMAS G. FESSLENDEN, Esq. for his excellent and useful Address delivered before the Society this day, and to request that the same may be published in the New England Farmer for the use of the Society.

Extract from the records of the Society.

N. BROOKS, Recording Secretary.

ADDRESS.

Mr. President, and Gentlemen Trustees of the Society of Middlesex Husbandmen and Manufacturers.

HAVING had but short notice to prepare for the present occasion, and a variety of other avocations presenting imperious claims to my attention, I am apprehensive I shall not be able to answer what may be deemed reasonable anticipations. The embarrassment, caused by these circumstances, is increased by reflecting that the subjects, which it would be proper for me to discuss, are not only of great importance, but have, heretofore, commanded the exertions and tested the powers of the first talents in the United States. I am invited to reap in a field where the harvest has been already gathered by such laborers as Mr. Madison, Mr. Pickens, Mr. Quincy, Mr. Lowell, and others, who carry a wide swarth, make clean work, and scarcely leave a single straw to be picked up by those who are called upon to glean on this same ground. Still, although my toils may produce but a pittance, they will, at least, serve as indications of good will towards the cause of Agriculture and the Useful Arts; and we know that the widow's mite was as acceptable as if it had been the largess of an Emperor, or the revenue of a kingdom.

The pursuits of agriculture have been held in the highest estimation among the wisest and most powerful nations. Indeed to neglect that art would indicate a want of wisdom, and the consequence of such neglect would be a want of power. Where husbandry excites but little attention, there can be but little worth attending to. The conveniences and comforts of life must be unknown; and even its necessities—its indispensables, must have a fluctuating and precarious existence. Distress waits on improvidence; want trends on the heels of indolence; disease and death close the ghastly procession. Thus famine was frequent among the aboriginal tribes of New England, and together with pestilence, its usual concomitant, desolated the land, and left large tracts of country without an inhabitant to impede the settlement of the pilgrims. The natives of this country owed these calamities, and at length their utter extinction, to their ignorance of agriculture, and want of acquaintance with those arts which gave subsistence, and minister comfort to civilized man. Had the poor Indians been Husbandmen and Manufacturers, this part of the continent would have been still possessed by its primitive inhabitants. Should we neglect the arts, and pay no attention to the pursuits of the Husbandman and

Manufacturer, we too must cease to be a nation; and our country will be occupied by a stronger, because a wiser people, to whom superior knowledge in Agriculture and Useful Arts has given superior power. The United States will then exist only in story, and occupy only a few pages in the annals of alien possessors of this goodly heritage of our Fathers.

Important as Agriculture is, Manufactures can hardly be deemed of less consequence. They must advance hand in hand, or they will both go backward. United they stand—divided they fall. They are the Urim and Thummim of national greatness, as well as the Alpha and Omega of individual prosperity. To talk of any clash in their interests is to speak of hostility between the right and the left hand of the same individual. If one is sick, the other will faint. If one perishes, the other must soon be annihilated. Agriculture without Manufactures would give us farmers without tools, and Manufactures without bread. Adam could not have dressed the garden of Eden without first becoming a mechanic, or being furnished with the necessary implements of husbandry by the Almighty Artizan, who exhibits the Universe as a sample of his Manufactures.

Since, then, not only our prosperity, but even our national existence depends on the successful pursuits of Agriculture and Manufactures, what can we do to promote them? This is a question of as great importance as any thing of a finite nature, which can possibly call for the exercise of the best intellectual powers and faculties given to man by his Creator. To state all which should be done would require a complete and very voluminous Cyclopaedia. I shall therefore confine myself to some remarks relative to what *ought not to be omitted*, if we wish agriculture to acquire and maintain that strength and stability which should be attributes of the principal pillar of public and private prosperity. As respects manufactures, I shall have but little further to observe; lest, peradventure, I should have more threads to my discourse than my staple will warrant—more irons in the fire than I can handle to advantage.

In order that agriculture may prosper,

- I. Its pursuit must be considered as honorable.
- II. It must be made profitable.
- III. It must be conducted with skill as well as with industry.

The pursuits of agriculture, are, probably, rising in public estimation. Still we do not believe they have yet risen to their proper elevation. That a further ascent may be effected, agriculture must continue to command the attention and patronage of men of wealth, of talents, of reputation, and of high official character. Persons who have it in their power to mould the manners and excite and direct the industry of mankind should not consider themselves as too great to be useful, and should throw the weight of their precepts, example, and influence into the scale of agriculture—they should employ their heads if not their hands, their money if not their personal labor, in promoting an art, which, if neglected, would

place them as well as their inferiors on a level with savages. They have great examples to serve as precedents. The Emperor of China does not think that it derogates from his dignity to act the part of a ploughman. The great Czar of Russia did not disdain to labor as a mechanic. Some of the principal noblemen in Great Britain are proud of being farmers; and many of them have added to their wealth, and gained distinctions more honorable than those of birth or title, by being authors of mechanical inventions and improvements. Washington likewise was a farmer, who gloried in his occupation. Yet among savages and dandies, and fools who are anxious to figure in high life, without manners or means, without wit, wealth or wisdom, contrary to the decrees of nature and the habits of nature, rural occupations are thought degrading; and to cultivate the ground is considered as the bitterest punishment of poverty, or the last shift of unsuccessful knavery.

The following is a vivid, and probably faithful picture of that kind of pride which causes some aspiring characters

“Downward to go, and backwards to advance.”

It was taken from real life, as it exists, or lately existed in a neighboring Province. It is not a caricature, nor was it meant to be a likeness of any thing belonging to New England. If then, any persons to whom we now take the liberty to exhibit it, should happen to perceive any similitude to their own features, or those of their friends, they may congratulate themselves on the resemblance, but may be assured that it is entirely accidental.

“When any of the farmers of Nova Scotia were so successful as to amass a little wealth, they were sure to escape from the plough and betake themselves to some other pursuit. The keeper of a tapping-house, the retailer of rum, sugar and tea, the travelling chapman, the constable of the district, were far more important personages, both in their own estimation and that of the public, than the farmer who cultivated his own lands. The farmer was thought to be of the lowest caste in society, and gave place to others, who, according to the European standard of rank and consequence, are considered his inferiors. This sense of degradation was perceptible among husbandmen themselves. Such of them as were under the necessity of working set about it with reluctance, and always under a mortifying sense of shame. They would blush to be caught at the plough by their gentler acquaintance, as much as if surprised in the commission of crime; and if they saw them approaching, many of them would skulk from the field, and plunge into the deplorable thicket. The children were easily infected with this humiliating sense of inferiority, and the labors of the farm were to the young men objects of avers on, as those of the dairy were to the young women. Hence the family were brought up with habits and feelings, inconsistent with their station in life; and that respectable class of men, known in England as the ancient yeomanry of the country, who were the owners and cultivators of their own lands,

had no footing in the Province. The profession of the farmer was considered as object, low and debasing. The daughter of a farmer, the least above poverty, demeaned her self by milking a cow. The sons, again, made little other use of the horses than to ride to church or market, and instead of being accustomed to ploughing, drilling, reaping, composting, and such like operations, they crowded to the capitol, as clerks and shop-boys, and many of them turned smugglers. The plough was far from being accounted honorable, and the handling of it was deemed an act of self-abasement."

Thus it is with mankind, the most preposterous of all beings. They glory in their shame, and are ashamed of their glory! We hope that the portraits we have exhibited, have no *fac similes* in the United States. That the off-spring of New England Farmers do not consider themselves as degraded by attention to the useful and honorable occupations of agriculture and rural economy. We have, however, seen the time when certain of the fair daughters of Columbia, were apparently more solicitous to make fine figures in a ball room than fine cheeses in a dairy room—would rather make pound cake for a tea party than an Indian pudding for a family dinner—would prefer spending the day in reading romances, visiting and receiving the visits of idle acquaintance to regulating the economy of the kitchen or pantry, mending or making their own apparel or that of their fathers or brethren. In short there once existed a sort of females, (now either extinct or out of fashion) who pored over non-sensical novels till they became so genteel, so indolent, so delicate, so romantic, so sentimental, so susceptible of every thing that is inexpressibly tender and exquisite beyond all conception—so very like the Cecilias, the Evelinas, the Docasmas and Cherubinas, whom they made their models, that they were as useless as butterflies, though as proud as peacocks! They considered themselves as too nice for the cares and duties of life; and if one of them was over-persuaded to marry a country suitor who cultivated the ground, she considered herself as no better matched than was the unlucky parrot in the fable, who formed a connubial union with an owl! I hope the ladies will pardon this sketch, when assured that there are probably none of this species of fallen angels now in being, at least in this part of creation. Time has been, also, when certain young men were so much superior to the Emperor of China, that they had rather tend a tavern bar than follow a breaking-up plough—would prefer figuring as dandy shop-boys with a hopeful prospect of being duly qualified for becoming broken merchants, to living respected and respectable, as hardy, independent, stout-bodied, strong minded yeomen, pillars of freedom, and capital columns in the social fabric. We speak of these things, however, merely by way of reminiscence—worthy to be noted among the memorabilia of former ages. Already, the wise and the worthy have set their faces against the ridiculous and pernicious pride to which we have adverted, and every good patriot stigmatizes such effeminacy, such meanness of spirit, such littleness of mind peeping from beneath the veil of pseudogentility, with his most pointed reprobation. This kind of false pride may now be numbered with the antiquated and exploded follies of the

hoop-petticoats and full bottomed periwigs of the belles and beans of olden time.

II. Agriculture must be made profitable as well as honorable. Unless this can be effected, we may found societies, multiply premiums, and deliver addresses, world without end, still husbandry, like a beautiful young lady of great pretensions but small property will have more admirers than suitors, will be more toasted than followed. The profits of agriculture consist in the value of its products after deducting the expense of cultivation. The slight culture, which produces but small crops, is very expensive, and often ruinous. None but *rich men* can afford to be *poor farmers*. In most cases if a farmer can double his crop, although at a considerable extra expense of manure and tillage, he will treble or quadruple his profits. Thus, if by 20 dollars expense of tillage and manure, a cultivator can raise 10 bushels of Indian corn on an acre, worth 75 cents a bushel, his profits, setting aside rent, will be ten dollars. If by 30 dollars expense in cultivation, he can raise, on the same land, 30 bushels, his profits will be thirty dollars. Thus by doubling the amount of his crop, he trebles the amount of his profits. Besides, his land, by being well manured and well tilled, is left in better condition for future crops.

It will, perhaps, be urged, by some, that individual farmers will gain very little, if any thing, by that general increase of the products of the earth, which is said to be the result of new and improved methods of husbandry; because the less there is grown, the greater will be the price of produce. But here Commerce lends her aid to her elder sister Agriculture, and enables the farmer to realize a handsome equivalent for his surplus produce. Population, likewise, increases in an exact proportion to the increase of the means of subsistence. If the farmer finds provisions, mouths to consume it will not long be wanting. Besides, it is said that New England is destined to become a great manufacturing district. But this can never be, unless New England is great in agriculture. The plough and the loom must be next door neighbors, or neither of them can long be driven to advantage. Manufacturers will be induced to settle where provisions are cheapest, and they will not be comparatively cheap in New England, unless agriculture is prosecuted with uncommon skill, as well as with indefatigable industry.

Improvements in agriculture are becoming the order of the day in America, as well as in Europe. It will be ruinous to an individual farmer to fall greatly in the rear of his neighbors, who are rapidly advancing. Like a man in a crowd, which is pressing in one direction, if he stoops through indolence, or falls thro' weakness or inadvertence, he will run a great risque of being trodden under foot. A man may afford to raise but 25 bushels of Indian corn on an acre, when his neighbors and those who supply the market raise the same quantity. But if 50 bushels becomes the average crop, and he continues at 25, the prosperity of others will run him.

III. We come now to the last head, which we proposed to consider, to wit, the skill or science necessary to make a man a complete agriculturist.

The handy works of husbandry—the mere

manipulations, such as using the scythe, hoe, axe or spade, may, in early life, be easily learned. But dexterity in those processes, although a valuable acquisition, will no more make a man a farmer, than knowing how to handle a broad axe and chisel would constitute him an architect qualified to superintend the building of a palace or a temple. To be a finished farmer is to be a philosopher, a botanist, a chemist, besides possessing a talent for observation, and an ample fund of good sound, practical sense. Good sense, however, is of more consequence to the cultivator than any, or indeed than all the other before mentioned qualifications. Science without good sense will be apt to fill a man's head with visionary schemes, and urge him on to ruinous projects. Such a person will be liable to form an attachment to erroneous theories and injurious processes, merely because he can give what he calls good reasons for being wrong; and will ruin himself by rule, according to sound maxims laid down by good authors—not because the maxims are incorrect, but because our gentleman-farmer, with every kind of sense but common sense, abounding in that kind of knowledge which profiteth nothing, whose light of intellect is like that of a jack a' lantern, glimmering to betray, misapplies his rules to cases for which they never were designed, and to which they are altogether inapplicable. Good sense without science is preferable to science without good sense, but the union of both is necessary in order to produce the best effect of either.

As science without good sense will sometimes lead into great errors, so industry without skill is not only of little avail, but often injurious. A man may work hard, but if he does not "work it right," he may as well fold his hands with the sluggard and give care to the wind as go to bed with the whip-poor-will, rise with the lark, and toil with the emmet.

It may be asked, in what does this skill, which is the essence of farming, consist? To answer this question would be to give a complete treatise on agriculture and rural economy. By attempting to do this, I should at once exhaust your patience, and betray my own incapacity. But lest you should think that I am stepping altogether out of my sphere in attempting to address experienced cultivators on subjects of this kind, I beg leave to premise that I had the honor to be bred a farmer, and wrought on and superintended a farm till about twenty years of age. Since that period I have never lost sight of my original occupation, but have attempted to add to my knowledge, derived from experience, by reading, observation, and conversation with practical farmers, on subjects connected with their profession.

By undertaking to survey the whole field of agriculture I should not only be lost in its immensity, but, by running over more ground than I can cultivate, be guilty of an error which has often been censured in my practical brethren. I shall, therefore, for the remainder of this address, confine myself to some remarks on soil, a knowledge of which may be said (without a pun) to compose the *ground work* of agricultural improvement.

"Let every planter, with discretion meet,
The force and genius of each soil explore,
To what adapted, what it shuns avise;
Without this necessary care, in vain
He hopes an ample harvest."

There are but four kinds of earth which constitute the globe. These are Clay, Sand, Lime and Magnesia. Lime and magnesia are so far similar in their properties, that for my purpose, it may not be necessary to treat of them separately. Stones are composed of these earths in a concrete and hardened state. Gravel is either aluminous (or clayey) gravel, silicious (or sandy) gravel, calcareous (or limy) gravel, or a mixture of two or more of these. Loam and marl, likewise, are composed of different proportions of these two or three sorts of earth. Clay, sand and lime, together with vegetable and animal remains, and comparatively minute quantities of salts and acids compose the vast varieties of soils which are denominated good, bad, wet, dry, cold, warm, light, heavy, rich, poor, barren, fertile, &c. &c. Every soil is more or less defective in proportion to the scarcity or entire absence of one or more of these ingredients. Clay without sand, or sand without clay, and both of these without lime, are like a stool intended for a tripod, with but one or two legs, worth little or nothing till the missing part or parts are supplied. The addition of manure, when clay, sand and lime are not all present, and properly mixed, will prove of very little service, except so far as the manure may chance to contain the kind of earth wanted to complete the composition of the soil. Considerable latitude, however, may be allowed in the proportions in which these earths may be mingled. A soil, composed of three eighths clay, two eighths sand, and three eighths of finely divided lime stone, is very proper for wheat. Likewise, eight ninths of calcareous marl, which is a compound of clay and marl, and only one ninth of sand, will produce good wheat. Sir Humphrey Davy found that a soil, containing eleven parts out of twelve of sand, would yield tolerable crops of turnips. A greater proportion of sand, however, produced absolute barrenness. Clay and sand may be mixed in any proportion from one ninth to eleven twelfths. That is to say, a soil may consist of clay except a ninth part sand, or of sand except a twelfth part clay. These two extremes, so wide from each other, leave a vast intermediate space to be filled up; and this accounts for the almost infinite variety of loams, all productive, which are met with in our globe. Lime is required, but small quantities will answer. A soil, however, which does not contain a portion of lime has a defect, which can be remedied by no other substance.*

To apply these rules we will suppose a soil to consist of pure clay and it is necessary that it should contain at least one ninth part of sand. It will then be proper to spread sand over it one inch deep, and mix it well with the harrow or cultivator. This will give one ninth sand, provided the tillage be nine inches deep.—Again, if the soil be pure sand, and it is necessary that it be mixed with at least one twelfth part of clay, spread over your field one half inch of clay, and the culture may be carried to the depth of six inches, and your soil will be cured of its barrenness. The constitution of your soil being thus changed, you may feed it with manure with a certain prospect of benefit resulting.†

* See Letters of Agricola.

† The following mode of ascertaining the constituent parts of soils is from the "Letters of Agricola," and is recommended for its simplicity, and the facility with

Lime is not only a necessary ingredient in every soil, which is intended to produce a vigorous vegetation, but it is wanted to *compose a part of the substance* of certain plants, and *wheat is one of the number*. No plant can grow in a soil which is utterly destitute of the earthy ingredients which must constitute its substance. Lime then is as necessary to raise wheat, as it is to make lime mortar; and unless that substance or something like it is found native in the soil, it must be supplied by art, or wheat, and some other plants of which it composes a part, cannot be perfected.

My opinions on this subject do not rest upon abstract theory alone, but high authorities and facts indisputable and unequivocal can be produced to corroborate them. The author of Letters of Agricola says, "It is fact that lime is indispensable to the production of superior wheat crops. The rye lands of Herefordshire, which were reported by Dr. Beale in the year 1636, as incapable of producing wheat, have been so much fertilized by the subsequent introduction of this fossil manure as to be successfully applied to the growth of that and every other grain. This and similar effects may be referable in part to the subserviency of this

which it may be accomplished, without having recourse to costly materials or implements of analysis.

In the field to be examined, take earth a little below the surface from four separate places, about one fourth of a pound, avoid dups, from each. Expose it to the sun, or before the fire, till it is completely dry; and turn it over frequently that it may be well mixed together. From the heap take exactly four ounces, and pass this through a fine sieve, which will allow all particles of sand and gravel to escape, but which will hold back stones, small fibrous roots, and decayed wood. Weigh the two parts separately, and take a note of each. The stones and other bulky materials are then to be examined apart from the roots and wood. If they are hard and rough to the touch, and scratch glass easily, they are silicious or flinty; if they are without much difficulty broken to pieces by the fingers, and can be scraped by a knife to powder, they are aluminous or clayey; or if when put in a wine glass and common vinegar poured upon them, small air bubbles ascend to the top of the liquid, they are calcareous. The finely divided matter which ran through the sieve, must next undergo the test of experiment. After being weighed, agitate the whole in water, till the earth be taken up from the bottom, and mechanically suspended, adding water till this effect be produced. Allow the mass then to settle for two or three minutes, and in that time the sandy particles shall have all sunk to the bottom. Pour off the water, which will then contain the clay in suspension, and the insoluble earth arising from animal and vegetable decomposition. The sand should first be attended to, and if from inspection, it be thought either silicious or calcareous in its nature the requisite tests may be instantly applied. By this time the mixture will have deposited at the bottom of the vessel the clay, and other earths, with the insoluble animal and vegetable matter. After pouring off the water, dry the sediment, and apply a strong heat by placing it on the bottom of a pot, ignited to redness, [heated red hot,] and the animal and vegetable matter will burn, and fly off in acridiform products. The remainder, lying in the bottom, will be found to consist of clay, magnesia or lime. To obtain accuracy, another one fourth pound of earth should be taken from the same heap, and the whole process gone over a second, a third, and even a fourth time, that the operator may rectify any blunders he had previously committed, and be satisfied as to the results of his experiment. He should provide himself with a pair of fine scales and a set of weights, divided at least into ounces and drachms. Although vinegar will detect lime by effervescence, it does not dissolve it so effectually as the nitric or muriatic acid, [aqua fortis, or spirits of sea salt] small quantities of which may be procured from the druggists at no great expense."

earth to the more perfect formation of the vegetable structure; for we know that birds, if confined to a cage, will lay eggs with soft shells. So wheat may labor under some analogous imperfection, unless the carbonate of lime comes within reach of its roots."

I might multiply authorities on this subject, but shall content myself with one more quotation from "Anderson's Recreations," a work held in high estimation in Europe.

"I had," says Dr. Anderson, "a field of good arable land, a mellow loam in Aberdeenshire, which had been long in culture, often dressed with animal and vegetable manures, and was of course endowed with a considerable degree of fertility; but being full of weeds it was subjected to a thorough summer fallow in order to get rid of these and bring it to proper tilth in other respects; and as lime is found to be an active manure in that district, it had a moderate dressing of lime put upon it, and some dung at the same time. The whole field was sown with wheat at the proper season, which sprang up equally thick on every part of it. For some time no difference was perceivable in the appearance of the crop over the whole; but by and bye, it was observed that the wheat on a small portion of the field, which by accident had not had any lime put upon it, became pale and sickly. While the crop in other parts of the field advanced luxuriantly, it dwindled in this particular patch more and more, till towards the beginning of May, the whole had died quite out, and not one stalk of wheat was to be found upon it, though the weeds in consequence of the richness of the soil at that time grew there with extreme luxuriance. Perhaps the proportion of calcareous matter did not, in this case amount to more than one thousandth part of the whole, yet the qualities of the soil were thereby totally altered, inasmuch that though before the application of that dressing, the soil was incapable of producing wheat at all, it was found at all times after that period well adapted for the raising of this crop. Nature has formed many soils with a similar proportion of calcareous matter, blended imperceptibly in them, over large districts of land."*

By this article it appears that small quantities of lime will produce a permanently beneficial effect, if applied to land which is destitute of that kind of earth. A quantity equal to one thousandth part of the whole would within reach of the roots of the plants commonly cultivated would not be a dear dressing even in Massachusetts, where lime is not remarkably cheap nor very plenty, yet that small quantity was found by Dr. Anderson, to be sufficient to effect a permanent change in the constitution of a certain soil, and enable it to produce good wheat, although previous to its application it would not ripen a single stalk. Larger quantities, however, would probably be beneficial. English farmers apply from 60 to 400 bushels of lime to an acre, as it measures when fresh from the kiln.

It may perhaps be asked, why new lands, or lands recently cleared from their native woods will at first produce good crops of wheat, but after having been cropped for a series of years, although made rich with manure, will lose the faculty of producing that vegetable? To this

* Anderson's Recreations, Vol. 1. p. 16.

it may be answered that, perhaps, the soil originally contained small quantities of lime, which became exhausted by tillage, and perhaps the ashes, which were left on the land in burning the timber, for clearing it, might furnish a substitute for lime, by yielding potash, a substance in many respects analogous to the alkaline earths.

I do not, however, mean to assert positively that Massachusetts can be made a wheat country merely by the use of lime as manure for wheat. Perhaps rust, or mildew, (for which by the way it is believed salt is an efficient remedy,) may prevent its being cultivated to advantage. It is possible likewise that the Hessian fly may destroy it, though, I am told that there are remedies against the ravages of that insect, and that some kinds of wheat are not liable to be injured by it. But I am very confident that wheat cannot be raised to advantage on most of the old lands of New England *without* the application of lime to the soil. Whether it can be profitably raised *with* such application can only be ascertained by actual and repeated experiments.

It is not in wheat crops alone that lime is found eminently useful. It is observed by Sir John Sinclair that "By lime spread upon a moory soil, good herbage is produced where nothing but heath and unpalatable grasses were before. By the same means grass-land, instead of yielding nothing but bent, and other inferior grasses, have been covered with those of a more valuable description. The utility of lime to turnips is so great, that though in the same field where no lime had been applied the crop died away; yet in the limed part, the turnips flourished with unabated vigour. The same writer mentions lands, in which manure previous to liming had no sensible effect; but after liming operated as on other lands.

A very great advantage in the use of lime consists in its tendency to pulverize, and make mellow strong clayey lands. That quality alone, by the saving of labour, and the more perfect division of the particles of the soil renders lime of very great value for hard lands. Quick lime, in powder, and probably lime water, applied by an apparatus similar to that made use of for watering dry and dusty streets would, undoubtedly be an effectual antidote against worms and other insects, which of late years appear to gain ground upon us in New England. And even when perfectly slack and effete, if laid about the roots of the apple trees it is said to preserve them against the canker worm. Lime should be laid on the surface and intimately mixed with the soil, for this purpose it is best slacked, and brought to a very fine dust, and the land should be made very mellow. It should be hot from the kiln when it is wished to dissolve peaty or woody substances. But in most other cases it is not material whether it is used as quick lime, air slacked, or pounded lime stone. Quick lime should not be applied to growing plants, as it will cause them to turn yellow, and if dissolved in water will kill grass if poured upon it. But quick lime applied to the naked ground soon becomes mild, and of course will not injure seeds sown some little time after its application, nor the young plants which such seeds may produce.* Too much lime is, in all cases, per-

nicious, and any quantity, great or small, is useless in exhausted land, unless it is accompanied or succeeded by other substances which will furnish food for vegetation.

If lime be so eminently useful and even indispensable in certain soils, and for the production of some of our most valuable crops, and more especially if its want alone prevents New England from being a wheat country, its value I believe has not, generally, been properly appreciated by New England Farmers. No American writer on agriculture, so far as I can learn, considers lime as a necessary constituent of every productive soil. It is mentioned as useful, but not as absolutely necessary for the production of any particular kinds of vegetables. And they do not appear to have known or reflected that "all soils are improved by mild lime, and ultimately by quick lime, which do not effervesce with acids;"* that is, that have not lime already as one of their constituent parts.

What I have said of lime, will, in most instances, apply to sea sand, shells, either of fresh or salt water origin, or marl; likewise in a degree to leached ashes, or any other substance, composed in part of calcareous matter. All these have more or less the properties of mild lime, and therefore may well be made its substitute.

But I fear that my respected audience are, by this time, convinced that quick lime is a *dear subject*; and though I hope its discussion may prove profitable to many, yet as there can be no particular pleasure in *hauling it*, I will no longer detain my hearers from the avocations of the day, and the amusements of the Farmers' Festival and the Manufacturers' Holiday.

quantity be given to land, and properly mixed with the soil, it is a thing of much less moment, than we are apt to imagine whether it be applied in its caustic or mild state, and for this reason, that there is a natural progression from one to the other, and in the end it is sure to be saturated with its full measure of carbonic acid.

Letters of A. C. C.

* Sir Humphrey Davy's Agricultural Chemistry.

CATTLE SHOWS.

We should be glad to give particular, minute and official accounts of the "Husbandman's Holidays," throughout the United States, if our limits would permit. But, to publish them at length, as they are given in the newspapers of the district in which they have taken place, would be to devote the whole of our paper for several weeks to details which are already in possession of many of our readers. We shall, therefore, give an abridged notice of each exhibition of which an account has reached us, and should we omit any thing of much importance, either as affording precepts or examples to our agricultural readers, we should be happy, hereafter, to give such *supplementary* notices as any of our correspondents may suggest as expedient.

CHESHIRE, (N. H.) CATTLE SHOW.

At Acworth, on the 2d day of October inst. in pursuance of previous notice, was held the annual meeting of the Cheshire Agricultural Society, and under its superintendence, the annual Exhibition of Stock and Domestic Manufactures, for the County of Cheshire.—The day was favorable. The occasion called together a numerous collection of the substantial citizens of

the County. At an early hour the Stock entered for premiums was arranged in the pens, and the Manufacturers deposited in a room provided for their reception.

The Society convened at 9.—The examining committees attended to their duties from 10 to 12. The drawing match under the direction of the committee for awarding premiums on working oxen, was attended at eleven. The display of the power of the ox which this trial of strength elicited was witnessed with much satisfaction. The pairs to which the first and second premiums were awarded, their age and size considered, were decidedly superior to any on the ground.

At 12 o'clock a procession was formed at the house of Mr. Keyes, which under the direction of the marshals of the day, Mr. Warner and Mr. Gove, moved to the meeting-house. The services were commenced by a prayer from the Rev. Mr. Cooke. An instructive and highly interesting Address adapted to the occasion, was delivered by the Hon. S. HALL. This address will probably be given to the public; an analysis of it will not therefore be attempted. The prominent subjects were the prejudices, existing against Agricultural Societies—a refutation of the objections which have been urged—remarks upon the policy of draining lands—upon the mode of increasing and applying manures, &c.—The reports of the committees on manufactures and on working oxen were then read by H. Hubbard, Esq. and the remaining reports of the committees at the house of Mr. Keyes, after the return of the procession. The services of the day were very pleasantly concluded by a liberal and well provided dinner.

The following reports were received from the Awarding Committees.

On Working Oxen.

The committee consisting of Col. David Parker of Charlestown, Chairman, Samuel Russell, of Swanzey and Mr. Joel Goss, of Claremont, awarded—

To Lemuel Towne of Stoddard for the best pair of working oxen, the first premium on oxen between 4 and 8 years old	\$6
To Benzla Cram of Unity for the 2d do. the 2d premium,	4
To Samuel Clark of Acworth, for the next best do.	2

The committee noticed a number of other pairs presented as being very fine cattle, particularly a pair exhibited by John Robbins of Alstead, which were brought on to the ground too late to be entered. They expressed their belief, that but for this omission Mr. Robbins would have been entitled to one of the premiums offered by the Society, and recommended that he receive a premium of one dollar out of the fund reserved to be appropriated at the discretion of the Executive committee. The recommendation was complied with.

On Steers and Heifers.

The Committee consisting of Isaac Hubbard of Claremont, Chairman, Aaron Hods-kins, Esq. of Walpole, and Mr. Thos. Whipple of Charlestown, adjudged—

To Royal Rounerval, of Unity, for the best pair of steers the 1st premium on steers	4
To James Diekey of Acworth, for the next best do. the 2d premium	2
To Samuel Tuthery of Unity for the best heifer, the first premium on heifers	4
To Aaron Dean, of Charlestown, for the next best do. the 2d premium	2

In addition to those above to which premiums

* The application of lime is matter neither of mystery nor of deep philosophical research. If the necessary

were awarded, the committee favorably noticed five pairs of three year old, and 2 pairs of one year old steers, presented by Mr. Frederic Stebbins of Acworth, and also several yoke of steers presented by Nathaniel Groat of Acworth, and Mr. Stephen Glidden of Unity—also a fine 2 year old heifer by Mr. Charles Bowen of Charlestown, and 2 two years old, and a yearling heifer, by Mr. Aaron Dean of Charlestown.

On Bulls and Cows.

The Committee consisting of Mr. Roswell Hunt of Charlestown, Chairman, Phillip Sweetser, Esq. of Marlborough and Silas Angier, Esq. of Keene, reported—

That Aaron Holdins of Walpole for the best bull, weighing 1211 lbs. at 20 months, is entitled to the first premium on bulls.

That James Bingham of Lempster for the 2d best do. is entitled to the 2d premium.

That Timothy Holden of Charlestown is entitled to the 3d premium for the next best do.

This committee observed that a bull presented by Mr. Matthewson of Acworth, and one by Daniel Breed of Unity—several young bulls less than a year old, from the stock of the bull owned by Samuel Tutherly of Unity, to which a premium was awarded at a previous exhibition, and from Mr. Walker's bull of Charlestown, merited the particular notice of the society, as being very superior animals, and as indicating an increased attention among our farmers to the improvement of their stock. They awarded no premiums on Cows—none having been entered, in their opinion, deserving.

On Sheep and Swine.

The Committee consisting of Stephen Johnson, Esq. of Walpole, Chairman, Mr. William Jennison, of Walpole and ———, reported—

To Uzzel Hurd of Lempster, the first premium on hogs.

To Rufus Brigham of Acworth for the two best pigs.

To Adam Wallace for the next best.

To Samuel Findlay of Acworth, the premium for the best Merino buck.

To Josiah White of Charlestown, for the 4 best Merino ewes.

On Domestic Woollen Manufactures.

The committee consisting of Th. C. Drew, Esq. Chairman, and Martin Butterfield of Walpole, and James Bingham, Esq. of Lempster, report—

To Mrs. Sally White of Charlestown the first premium on fulled cloth.

To Samuel Findlay of Acworth, for the best piece of flannel the first premium.

To Abner Chase of Lempster for the next best do.

To Samuel Shade of Acworth, for the best pair of woollen blankets.

To Thomas Whipple of Charlestown, for the best woollen coverlet.

To Samuel Findlay of Acworth for the best piece of kersycmere.

The committee recommended a premium of fifty cents to Larissa Miner, of Lempster, for an excellent pair of woollen hose, and remarked that they would gladly have assigned a premium to Dudley Lewis, of Marlow, for a pair of cotton and woollen coverlets, had any have been offered by the Society upon that article of Manufacture.

On Cotton and Linen Manufactures, and Straw Bonnets.

Mr. Vryling Lovell of Charlestown, Chairman, James H. Bingham, Esq. of Alstead, and Mr. George H. Ingersoll of Charlestown, the committee, adjudged—

To Miss Peggy McClure of Acworth, the first premium on Linen.

To Martha Duncan of Acworth the 2d do.

To Jane Rob of Acworth, for the best piece of linen diaper, the 1st premium.

To Lydia Thayer of Acworth, for the next best do, the 2d premium.

To Selina Parker of Fitzwilliam, for the best grass bonnet, the 1st premium.

To Nancy Fletcher of Alstead, do, the next best do.

To Betsey Ruggles of Walpole, for the 6 best straw bonnets.

This committee remarked that Miss Peggy McClure would have been entitled to the 2d premium on linen had the piece she presented contained a sufficient number of yards. Two various specimens of linen thread were presented which were very creditable to the manufacturers, particularly a bunch by Miss Peggy McClure, and a bunch by Mrs. Slader.

A few articles besides those noticed above, for which no premiums had been offered, were presented for examination. Among these were an improved plough by Mr. David Farnsworth, of Washington,—and an improved shearing machine by Mr. Parks, of Acworth.—The executive committee esteemed the improvements valuable and recommended them to the notice of the public.

As a whole the exhibition was gratifying to the friends of the institution and creditable to the County. The anticipations of all, so far as they related to the numbers assembled, to the variety and quality of the Stock and Manufactures exhibited, may with truth be said to have been more than answered. The zeal and interest with which all engaged in the business of the day—the very considerable number of fine animals presented—the obvious improvement in the young stock—the taste and ingenuity displayed in the Domestic Manufactures, all combined to evince that the Society has exerted a highly beneficial influence upon the agricultural interests of the County.

If with the limited patronage it has thus far received it has been productive of so much benefit, how much greater may be expected to be derived from it when patronized to the extent which the intelligence, population and resources of the County would warrant.

For the next anniversary the funds of the Society, it is expected, will justify the offer in premiums of a much larger amount, embracing a greater variety of objects, than was offered for the past. If so it is hoped that a corresponding competition will be excited and that the result will be honorable to the County of Cheshire.

THOMAS M. EDWARDS,

for the publishing Committee.

BERKSHIRE CATTLE SHOW.

The 12th anniversary of the Berkshire Agricultural Society was holden on the 2d and 3d inst. The first day was occupied in the exhibition of Cattle, Sheep, Horses, Swine, Domestic Manufactures, Agricultural Implements, and in organizing the Committees for awarding premiums.

On the second day the exhibition of the Ploughing Match took place in the morning. This was succeeded by sacred and literary exercises—a prayer by the Rev. Mr. Humphrey, and an appropriate, useful and able Address, by Maj. McKay, which is expected soon to appear in print.

The declaration of premiums was announced by the first Vice President, Hon. H. W. Dwight, preceded by some suitable and elegant comments. The Society sat down to an excellent dinner at Capt. Campbell's. The weather was fine, and it is worthy of remark, that in this particular Providence has smiled on this society at every anniversary since its formation. The quantity of domestic manufactures was much increased, and the quality much improved, and such as justly distinguished the Ladies of Berkshire for their ingenuity and industry. The number of animals was not so large, but in quality they were superior to those which have been exhibited at former anniversaries. The number and excellence of the Merino Sheep were worthy of particular comment—in which it is believed the County of Berkshire is not exceeded by any other county in the U. States.

The following is extracted from the Report of the Committee appointed to award premiums upon Live Animals.

“Twelve years only have elapsed since the first exhibition of animals was made in Berkshire, under the name of a Cattle Show; since that time, it is plain and obvious that our breed of cattle has been much improved; and the young stock exhibited at this time is much superior to the old.

“It is a fact well attested, that not more than forty years since, the animals raised in Great Britain were much inferior to those now raised in this country, and that for a century previous, very little improvement had been made in their beauty and size. About that time associations were formed by the most wealthy and respectable farmers, Cattle Shows were held, and premiums given for the best animals offered. The effect produced is obvious to any one, who has examined the Cattle imported from that country.

As evidence of the truth of this, we refer you to the two beautiful Heifers of the Devonshire breed, exhibited by our first Vice-President; and although purchased at what may, by some, be considered a high price, still we presume the speculation may be a profitable one to the enterprising owner. It is extremely desirable that the most wealthy and opulent farmers in Berkshire may duly appreciate the advantages that may accrue, not only to themselves, but to the whole community, from similar exertions. It is within the recollection of many gentlemen in this vicinity, that great improvement was made in our breed of cattle by the introduction of the Cox, or short horned breed. The Sack-or breed, so called, which originated from this stock, are to be preferred to any of the original stock of the country. Although purchasing imported cattle may be the most expeditious way to improve our stock, still we do not believe it to be the cheapest way, for we believe the native stock of our country may be made superior to those we now import. This, however, must be a work of time to effect. Is it not for the interest of every farmer to begin this work? The small farmer can aid in it as well as the large one. Keep no more stock than you can keep well. Select your best Cows to breed from. Take the same pains with respect to the breed on the other side. If you have more calves than you choose to raise, do not kill the largest and best of them, as is generally the practice, because they will bring a few cents more than the others. Nurse your calves care-

fully during the first years growth. Unless you lay the foundation for good cattle during that time, you will never obtain the object wished for."—*Abridged from the Pittsfield Sun.*

The Plymouth County Agricultural Society

Held their annual exhibition at South Bridgewater, on the 3th inst. An Address was delivered by Dr. Hector Orr. Dr. Orr referred to the circumstances in the history of the Old Colony, which had been unfavorable to the due improvement of its agriculture—adverted to some erroneous opinions, and existing defects in their husbandry—and characterized the loose and indolent habits, that originated in most cases the propensity to emigration, by strokes of skilful and well merited sarcasm.

"The exhibition of stock was superior to the last year. The Bulls, particularly that which obtained the premium, and one belonging to Gen. Washburn, furnished an assurance of still further improvement. The Manufactures, though limited in quantity and variety, would not in their quality dishonor any exhibition in the state. The ladies Bonnets, made of rye straw, the thread and worsted Hose and the braid hearth rug were noticed and admired. The Cloths from the several Factories were spoken of in terms of commendation. The Ploughing Match was engaged in with a zeal and emulation, that proved the Agricultural community had received a stimulus from the exertions of the society."

Abridged from the Old Col. Memorial.

The Hartford County Agricultural Society

Held their fifth anniversary at the City of Hartford, on the 9th and 10th of Oct. The exhibition was superior to any which preceded it. The Bulls, Cows and Working Oxen are spoken of in terms of high commendation in the Connecticut Courant. Twenty-eight premiums were awarded. With regard to Domestic Manufactures, the Courant observes, "Here was a display, which, when compared with that of last year, was flattering to the prospects of the Society. The articles offered for premiums were greater in number, and by far superior in quality, to those offered the last year." Among the specimens are mentioned "several pieces of blue woollen cloth, which, though spun, wove and dyed in families, were scarcely inferior to the best factory goods. Mixed cloth, fine flannels, carpeting, stockings, hearth rugs, linen diapers and woollen blankets of fine quality were also exhibited."

Twenty-four premiums were awarded by the Committee of Manufactures. There was exhibited a hat made of mole skin, in imitation of *Chinchilli*, which indicated much ingenuity. Also, two cassimere shawls, which were considered worthy of particular notice, as being the first of the kind offered. These three articles were presented by Miss Susan H. Hubbard, of Windsor, and for which the Society awarded her an extra premium. A Stand and Card Table by Mr. Daniel Dewey; a Sofa by Messrs. Foster & Shepherd; beautiful ladies' Combs by Mr. Levi S. Platt; a fruit piece, painted by Mr. Laughton; a Threshing Machine, invented by Mr. James Gregg, of New Hampshire, are likewise mentioned in favorable terms.

The public exercises were, a Prayer by the Rev. Dr. Flint, and an able and instructive Ad-

dress by the Hon. Timothy Pitkin, President of the Society, on the objects of the institution.

The Society has a Viewing Committee, who award premiums for the best cultivated farms. This committee gave favorable reports of the farms of Mr. Lemuel Roberts, in Windsor; Mr. Frederic Oakes, in W. Hartford; Daniel Wadsworth, Esq. and a Mr. Raphael, of Hartford. The premium for the best cultivated farm, being a silver cup, to the value of \$10, was awarded to Daniel Wadsworth, Esq. and that of the second best, being a silver cup to the value of \$20, to Mr. Frederic Oakes, both of Hartford.

TO THE EDITOR OF THE NEW ENGLAND FARMER.

SIR—Being of your opinion "that it is the duty of every man possessing any information tending to advance the agricultural interests of his country, to lay such (however inelegantly communicated,) before his fellow citizens," I deem it not amiss to send you my opinion, (founded on some experience,) respecting the time most suitable for cutting English Grain, which in New England, as far as my knowledge extends, is permitted to stand in the field two or three weeks later than *good husbandry demands*.

European writers, I believe, are unanimous in the opinion, that when the *milky* substance has passed from that state into *flour*, the sooner the grain is cut the better, as all after this, it permitted to stand, is taking value from the straw, and adding to the berry or kernel, what? a thick, dark and bitter skin! thereby rendering the bread made from such grain dark, clammy, and unsavory to the taste, if not unhealthy to the stomach.

From an experience of several years in cutting my grain as above recommended, I consider its value to have been enhanced one quarter part, as the grain is not only more *white* and *sweet*, but the straw is likewise of double the value for fodder of that cut late, when the grain is dead ripe. I can with confidence assure my friends of the *plough*, that if they will cut their grain early, (*viz.* when the kernel is tough and spongy, and feels like India rubber) they will sustain no loss from shrinkage, as grain after it has arrived at this state, can receive no more nourishment from mother-earth; that the excellence of the straw will doubly compensate them for the trouble of haying it after it is cut; that instead of dark bitter rye, they may have that, which in point of color and sweetness, may vie with the late cut wheat.

Plaster of Paris.—Three years since I used one ton of Plaster of Paris, one barrel of which was sown on mowing on the top of a heavy swell of land, which to appearance had little or no effect, till the present summer, when the land was broken up, and the sward, in true Brighton style, turned bottom up, for a crop of English turnips. The weather which followed the sowing was unfavorable for this vegetable, but to my surprise I discovered that, where the plaster had been sown, three years before, the turnip plants were vigorous and thrifty; each side of which the drought had destroyed them almost to a plant! At this time, (Oct. 1st) the turnips on the *favoured spot* are the size of a coffee cup!

Now, Mr. Editor, this same Plaster of Paris, (or capricious Gypsum, or whatever other term it may have) has caused the gentlemen of the

plough handles more puzzle as it respects it acting as an auxiliary to forward vegetation than almost all the rest of our unaccountable put together. A friend of mine, Dr. W**** having purchased a large plantation on the Hudson river, N. Y. had, he informed me, made use of many tons of this article, to very great advantage, and is of the opinion, that it acts more by *fermentation* within the earth, (thereby preparing food proper for plants in a greater degree) than by its agency in *attracting* nitre or any other property contained in the atmosphere. My turnips give evidence to such an opinion.

The above remarks on Gypsum are not made so much with a view of their enlightening any one, as of eliciting observations from more experienced heads and abler pens. With the apology, that many who can hold a plough to admiration, make but a bungling job in wielding the pen, I shall subscribe myself your humble servant,

A YOUNG FARMER,
Of the heart of Massachusetts.

Oct. 1, 1822.

From the London Farmers' Journal.

RECIPT FOR MAKING GREEN GRAPE WINE.

Lewisham Nursery, Oct. 7. 1821.

SIR—Having for a number of years been very fortunate in making British Wines, I herewith send you a receipt for making Green Grape Wines, which is particularly applicable this late season, as there are many farmers, and others in the country, who have large quantities of grape that will not ripen, and which they will find, by making use of them in this way, will turn to a very good account. Care must be taken to have the casks, bottles, &c. very sweet and clean, and I have no hesitation in pronouncing this the finest British wine that can be made.

I am, Sir, your obedient servant.

JOHN WILLMOTT.

To make Champagne from Grapes equal to foreign

Gather the Grapes when they are just turning or about half ripe; pound them in a tub, and to every quart of berries so pounded, put two quarts of water: let it stand in a mash tub, for 14 days when it is to be drawn off; and to every gallon of liquor put three pounds of lump sugar when dissolved, cask it, and after working, bung it down. In about six months it will be fit to drink, when it should be bottled and tied down, or wired, if it is intended to be kept more than one year.

An awful instance of sudden death occurred a few days since near Worthing. A gentleman of the name of Home, having occasion to paint his house, incautiously remained in it, contrary to the advice of his friends, during the time the men were employed. On the fourth day he was seized with vomitings, and complained of a giddiness in the head. A physician was immediately sent for, but before he could arrive, the unfortunate man was senseless. Every means which medical skill could devise were tried for his recovery, but without effect. He has left a wife and two children to lament his untimely death.

Ibid.

Important!—His Majesty, says an Edinburgh paper, landed at Leith, on a large piece of mahogany, which is intended to be cut up, and made into snuff boxes!

N. E. FARMER.

BOSTON:—SATURDAY, OCT. 19, 1832.

We have omitted giving, in the present paper, any further notice of the Brighton Cattle Show, because we supposed it might be more acceptable to many of our readers to include the *official reports of all the different Committees* in the same number. We could not give them entire in the present number, and therefore have deferred their commencement to our next, which will include the whole.

Mistake Corrected.—In our last paper it was stated, (p. 86, col. 1, near the bottom) that "Mr. S. Jaques, of Leicester, received a premium of \$50, for a breed of long woolled sheep, 6 ewes and 1 lamb." It should have been *Samuel Jaques, Esq.* of Charlestown, who was the owner of the animals. The mistake was copied from the Daily Advertiser.

FOREIGN.

London papers to the 14th Sept. have been received at New York. Mr. Canning has been appointed Minister of Foreign Affairs. The state of Spain has become more tranquil, and the new ministry is said to be popular.

The Greeks are gaining ground of the Turks. One of the Turkish Pashas was defeated on the 20th July. The account adds, that threatened by the Divan, he assembled all his reserves, and led them to the theatre of his defeat; but the Greeks again intercepted him, and on the first of August he lost as many lives as on the 20th of July, and was himself taken prisoner.

DOMESTIC.

Gale of Wind.—The papers are replete with accounts of a severe gale experienced in the Southern States on the 27th and 28th ult. At Danville and Lynchburgh, in Virginia, it commenced about half past 1 o'clock in the morning of the 28th. It was very severely felt in the destruction of buildings, orchards, &c. Fifteen houses on Sullivan's Island, near Charleston, were blown down. Upwards of one hundred dwellings in the city of Charleston have been unroofed, and about one thousand have been rendered pervious to the rain, by the loss of tiles or slating. Among the public buildings the City Hall has been considerably injured. Not one place of public worship escaped. The theatre was unslated and otherwise injured. About 35 persons lost their lives in Charleston and on Sullivan's Island.

At Georgetown, S. C. we are informed the gale was still more severe than at Charleston. The house of Dr. Meyers was swept off by the flood, and his whole household, fifteen in number, including his wife, three daughters and a son, were drowned. The dwelling house of Mr. R. F. Withers, a large new building, and very out building were also destroyed, and fourteen out of eighteen persons lost their lives. Fifty lives were lost at or near Georgetown.

The Cattle Show and Fair of the Hampshire, Franklin and Hampden Agricultural Society will be held at Northampton on Wednesday and Thursday of next week. Address by JOHN MILLS, Esq. of Southwick. There will be a Concert of Sacred Music in the evening of the first day.

The imitation Leghorn Bonnet manufactured in Vermont, and which was considered superior to any previously made in this country, was sold at Brighton, on the second day of the Show, for *eighty dollars*.

Two winter squashes were raised in the garden of George Olney, Esq. this season, of the following dimensions and weight:—First squash, length 39 inches; greatest circumference 34 1-2; smallest do. 27; length of neck 29; average circumference of neck 29; weight 1 1-4 pounds.—Second squash, greatest circumference 1 1-2 inches; smallest do. 21; length 37; length of neck 26; average size of neck 26; weight 53 1-4 lbs. A cucumber was also raised in the same garden, 17 inches long, and 10 inches in circumference at the largest part.—*Providence Gazette*.

At a factory of Waltham.—The deficiency of rain during the present season has caused great injury to the profits of a large manufacturing establishment in this vicinity. The *Waltham Factory*, which employs between 7 and 8000 spindles, has been deprived of more than half its water power by the drought; and this circumstance has materially diminished the dividend of the Stockholders. On Tuesday last, the *annual dividend* was paid, amounting only to 12 1-2 per cent.; whilst, last season, the profits were 30 per cent. per annum.

Imitations of the Waltham Cotton have been sent from England to this country, for sale; but the English manufacturer cannot make an equal fabric at the same price. The imitation is thickened with flour, to give it the appearance of firmness.

Worcester Canal.—The surveys for the projected Canal, from Worcester to this place, have at last been completed in a manner very satisfactory to the Committee. The descent from Worcester to this place is, as we lately stated, a few feet more than 450. The ground was bored every twelve rods, the whole distance. On the route selected, no rock was found, within the depth for excavation, excepting at three places, where it rose above the surface. The gentleman employed as Engineer, in this survey, whose experience and judgment may be fully relied on, estimates the expense of the whole work, including sixty locks, at \$323,000. He thinks, that locks of six and eight feet each are preferable to those of higher lift, as they may be constructed at a smaller proportionable expense.

These facts enable us to repeat, with much confidence, the opinion which we gave, some time ago, that the stock of the Canal will be more profitable than that of any description of public debt, bank stock, or even manufacturing establishments.—*Procr. Journal*.

The beautiful river which runs through Ipswich, and which is never dried up by the severest droughts, is destined soon, we understand, to become the busy seat of manufactures, a monied association from the capital having purchased a right upon the stream for that purpose. Ipswich has long been spoken of as a future manufacturing place.—*Salem Gaz.*

United States Law Journal.—It was mentioned in the Statesman, a few evenings since, that the second number of this work had made its appearance. We have since had an opportunity of perusing its contents, and do not hesitate to pronounce it a highly interesting and valuable publication. In the compass of 360 compact octavo pages, is presented a body of information on legal subjects, and great national questions connected with our Judicial institutions, which cannot be conveniently derived from other sources, and which cannot fail to commend the work to a numerous class of readers, particularly to gentlemen of the bar, legislators and jurists. The second number is in all respects superior to the first; and if the independence and spirit, the talent and taste, evinced at the outset, shall continue, the Law Journal must soon assume the character of a standard work, and reflect credit upon the jurisprudence of our country.—*N. Y. Statesman*.

Sickness in Pennsylvania.—Letters from Philadelphia give a deplorable picture of the ravages which have been committed this season, in the vicinity of that city, by bilious and intermittent fevers. One physician at Moorstown, N. J. nine miles from Philadelphia, is stated to have 120 patients now under his charge; and in many families, on the banks of the Delaware and Schuylkill, not a sufficient number of healthy persons remain to attend the sick. The Democratic Press notices six deaths in Montgomery township, and remarks, that it seldom happens in a township of less than a thousand, so many die within a few days of each other; and it is still less seldom, that six old neighbors should die, whose united ages should amount to 455.

—*N. Y. Spectator*.

M. Durad, manager of the repository of inventions at Paris, has invented an instrument of a novel and elegant description, which he calls *caille-maine*, and with which roses and fruit may be gathered from thorny trees without any injury to the hand; it is like a pistol. *London paper*.

Mines of North Carolina.—We continue to hear of the discovery which has lately been made, of gold and silver mines in Lenoir County, (N. C.) Some incredulous persons seem to have attempted to turn the matter into ridicule; but the actual exhibition of the precious metal itself, has silenced them; and it is now acknowledged that a bar of silver, and a lump of gold, as large as a man's thumb, have been extracted from part of the ore, which is found in abundance on four or five plantations. A ridge, more than a quarter of a mile in length, is supposed to be full of this valuable substance.

—*N. Y. Spectator*.

EDD.—At Slough, near Windsor, in England, Aug. 25th, Sir WILLIAM HERSCHELL, aged 55, one of the most celebrated Astronomers of the age.

In Bangor, Me. HEN. LOTHROP LEWIS, aged 58—one of the most eminent Geographers and Mathematicians of New England. At his death he was one of the Commissioners of Maine for dividing the Massachusetts and Maine Public Lands.

WANTED IMMEDIATELY.

A N active, intelligent Boy, 15 or 16 years of age, as an Apprentice to the Printing business. Inquire at the Farmer Office, *Oct. 19.*

From the Columbian Centinel.

HUSBANDMAN'S HOLIDAY.

Again, on the wing of old time, has come round,
The husbandman's holiday—londless and bright;
Our spirits still buoyant, and bosoms still sound.

With smiles let us welcome its pathway of light;
Then hail! to our jubilee, glory and pride,
When we lay by the Plough—cast the sickle aside,
Nor envy the fane
Of the warrior's name.

Enchained with garlands, in victory dyed,

God of Seasons! to thee shall our praises ascend,
To thee, the first fruit of our harvest shall flow,
Hallowed strains with the smiles of festivity blend,
And gratitude warm in our bosoms shall glow;
In this clime of the West, shall thy altars be reared,
Thy name and thy glory be loved and revered,
And oft we will raise

The loud anthem of praise,
For a country and home by thy blessings endeared.

Let others exult in their prowess or might,

Or in sky piercing Temples which slavery gilds;

The brightness of Despot's is sinking in night,

And crumbling the monument Tyranny builds;

For a season, Ambition may dwell in its tower,

And crime every vestige of greatness devour,

But soon from on high,

With an Eagle-trained eye,

Retribution and justice shall vengeance lower.

Italia and Greece! with a climate as mild

As your vile pampered sons are degenerate and base,

On you awful wisdom and science first smiled,

And learning was fostered within your embrace;

But now, wreathed in luxury's train,

You bow at her footstool and worship her reign;

Oh! when shall a ray

Of your earlier day

Enkindle the spirit of freedom again.

Thrice happy New England! the home of our choice—

No foul blot of guilt thy escutcheon have stained,

Thy sons in the blessings of plenty rejoice,

And glory in freedom their valor maintained;—

Hail! hail to the era that happiness brings,

In our forests no longer the battle shout rings,

And over our land,

Unswelled and bland,

The Angel of Peace spreads her balcyon wings. F.

An astonishing surgical operation was lately performed with success in the hospital of St. Louis, at Paris. A peasant of the neighborhood of La Fere was persuaded that about five years ago he had swallowed with his food some reptile which in an inexplicable manner still lived, as he affirmed, in his stomach. The Physicians employed various prescriptions without effect. Tortured by excruciating pains, the unhappy man resolved to go to Paris to be opened; which operation was in fact performed by making an incision just below the region of the heart, when it was ascertained that his conjecture was well founded. As soon as the animal perceived more air than it was accustomed to, it showed itself at the end of the incision, but immediately drew back; when one of the assistants put his finger into the wound and drew out a snake two and a half feet in length, and eight or ten inches in circumference. It lived sixty hours. The patient felt great relief, and is in a situation which gives no reason to apprehend any bad consequences.—*London paper.*

A small farmer in the vicinity of Manchester, not long since, killed a cow, and sent part of the beef and a quantity of suet to his son, a weaver in Blackley, who hung it up somewhere in the window, that some one in the night broke a pane and carried off the suet. In the morning the weaver missed his suet, went to the alderman, where he posted up the following advertisement, which still remains as evidence of the right John Bull generosity and spirit:—"Whereas last night a quantity of beef suet was taken from the house of Thomas Wadstoncroft, this is to give notice that if the person who took it away will appear and prove that he was forced to do so by distress, the said Thomas Wadstoncroft will give him a good reward to make the suet into dumplings. But if he cannot prove that he was in distress, Wadstoncroft will give him a good reward to make the suet into dumplings. But if he cannot prove that he was in distress, Wadstoncroft will give him a good reward to make the suet into dumplings."—*London paper.*

THE NEW ENGLAND FARMER,

PUBLISHED BY THOMAS W. SHEPARD, ROGERS' BUILDING, CONGRESS STREET, BOSTON.

SEVERAL numbers of a Newspaper, with the above title, have been published in Boston, and have met the approbation of intelligent Agriculturists, and an enlightened public. The following remarks relative to this publication, are the result of the unbiassed and disinterested deliberations of highly respectable and very competent judges, whose names, and the observations to which their signatures are attached, must render farther recommendations superfluous.

NEW ENGLAND FARMER.—Published by Thomas W. Shepard.

The opinion of the subscribers having been requested in favor of this publication, with the avowed and very proper wish, on the part of the publisher, that it might tend to the increased circulation of his Journal, (the first, avowedly devoted to the interests of agriculture in New England,) we cheerfully afford our testimony, as far as it may be of any value to him. Though the American public, when compared with that of other nations, may be considered a thinking and reading one, yet from various causes, which it cannot be necessary to state, much the greater part of its reading is confined to, and its information obtained through daily, weekly and other periodical journals. In a country, in which the Elective power as to almost all offices, is enjoyed and exercised by the great mass of the people, it is natural, that politics, including the national state, county and town interests and concerns, should occupy much the largest share of our public journals—next to the commerce and manufactures must of necessity hold a high rank. These require so much more constant and more accurate information—so much in those branches depends on political, commercial and agricultural events abroad—so much on the state of foreign markets, on losses and disasters at sea, that it is no surprising that nineteen twentieths of all our newspapers are occupied either with politics or commercial news. So much is this the case, that it was doubted for a long time whether an Agricultural Newspaper could be supported—but the success of the American Farmer, printed at Baltimore, by John S. Skinner, Esq. and the Plough Boy, at Albany, by Solomon Southwick, Esq. has proved that there is a sufficient degree of zeal and intelligence and desire of knowledge among the cultivators of the soil to sustain a few purely agricultural papers. If one is to be added to the two, which now exist, among the several thousand Newspapers now printed in the United States, it would seem that New England is in its natural and most proper situation, and best so as conveniently placed for its publication and correspondence, as any place in New England. We hope we have as many thinking and reading farmers in the Six New England States, not only as any other portion of this country, but as any equal portion of the cultivated world can afford or furnish.

It seems to be absurd, that farmers should subscribe for papers devoted exclusively to questions in which they have only a remote interest, and should decline giving their aid to one entirely devoted to their instruction, amusement, and to the record of their improvements, doubts, queries, discoveries and speculations. The paper now commenced has every thing to recommend it as far as we have had an opportunity to judge. Mr. Shepard is well known as an editor of a valuable paper at Northampton. That he has all the professional skill, and the requisite liberality in the execution of his work, is manifest by the numbers already published. They are neatly executed on good paper and with a fine type, with great care and accuracy, far above, in these respects, (we may say, without offence, we hope,) any other like publication. His present assistant, THOMAS G. FISSENDER, Esq. is a man of reading and talents, and has paid great, and for our country, most unexampled attention to agricultural subjects. His mind is philosophical, and his attention is undistracted by other pursuits. His life has been principally devoted to such subjects. The numbers as yet issued are respectable, as much so as could be expected, before the public at large had taken an interest in the work. We hope that it will succeed, but that must wholly depend on the aid which the intelligent Divine, Lawyers, Physicians, and practical Farmers in the country will afford it. That aid must consist not only in taking it and paying the subscriptions—that to be sure, is its necessary food, without which it must starve—but in favoring it by communicating their thoughts, experiments, objections to existing practices, or to new projected improvements. It should be remembered, that this is a mere Newspaper, and therefore, that a man would not write a book in his own name, or an article for the Massachusetts Agricultural Repository need have no scruple in writing for this.

AARON DEXTER, President of Massachusetts Agricultural Society.

S. W. POMEROY, 1st Vice President.

The New England Farmer is published weekly, on Saturdays. Each No. contains 8 quarts pages, printed on a sheet of good quality, with an entire new type. The price is \$2.50 per annum, in advance, or \$3.00 at the close of the year.

Each volume will comprise 52 numbers, and the present volume commenced the first Saturday in August. A title-page, and a correct and copious index will be given at the end of each year.

Persons who will procure seven subscribers and become responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

Congress-street, Boston, Oct. 1822.

Our Editors of papers with whom we exchange, by giving the above an insertion, will confer a favor which we shall be happy to reciprocate when an opportunity offers.

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I.

BOSTON, SATURDAY, OCTOBER 26, 1822.

No. 13.

CATTLE SHOWS, &c.

OFFICIAL REPORTS
OF THE CATTLE SHOW AT BRIGHTON,
Oct. 9th & 10th, 1822.

No. I.

On all the larger Horned Cattle (except Heifers.)

The Committee report that the animals in this branch of live stock, were unusually numerous and good, proving, that a gradual and regular improvement is steadily, and as rapidly as could be expected, taking place. The number of entries for premiums, in this department alone, amounted to 42, and of individuals (many entries comprising more than one) to 52, while the whole number of premiums offered, and granted, are only 10, so that four fifths of the competitors were necessarily thrown out.—This is inevitable, unless our funds should be exceedingly increased, or unless we should make our premiums smaller, and more numerous. This might be liable to great objection, by extending rewards to animals of inferior merit, and thus diminishing the motives to make the breeds as perfect as possible. While the beneficial effects of the liberal premiums offered by the Society, for the importation of the most improved breeds of foreign countries, is every year evinced by the crowds which, from the beginning to the end of our shows, gather round the imported animals, and their improved progeny, we ought never to forget the sound advice of the venerable farmer who addressed the Society this year, "that the progress of improvement by foreign crosses must be very slow;" and possessing as we unquestionably do, the materials among our own stock of improving our breeds by careful selection, we should follow the example of Bakewell and the other British farmers, who in fifty years have raised the stock of Great Britain to a state of perfection little short of what it is supposed they can ever reach. And, who at the late show had the pleasure of viewing those fine animals, Denton and Coelebs, could doubt whether they were superior to any animals of the same description now to be found in New-England? And why is this the case? Assuredly our pastures are as fine, and the race has not degenerated with us. Wherever a pride is felt in raising fine stock, our success is perfect, and the single town of Sutton might send its team of 120 oxen and challenge Devonshire or any other county of Great Britain, to trials of strength or activity.

Let us then, on this occasion, earnestly solicit our farmers to select and propagate only the best individuals of their horned cattle. If they reply, we feel no encouragement to do this because we find the improved crosses always preferred at your shows, we reply that though this is partially true, it is not entirely so, and what would the farmer have us do on such an occasion? If, in fact, the full blooded or half blooded descendant of imported stock is superior, shall we refuse to admit it so to be? This would be indeed sacrificing the best interests of our country in relation to this object, as well as violating our solemn pledges, to gratify an improper na-

tional prejudice. Our true course is to strive to equal or surpass the foreign races by selections and careful management of our native stock. It was upon this principle that our manufactures have been built up on the only solid foundation. Instead of complaining that foreign goods were preferred, our citizens have exerted themselves to make our own better as well as cheaper; and let Manchester and Yorkshire beware, lest they find themselves not only shut out from our markets, (not by prohibitions but by skill and industry) but eventually rivalled in those of foreign countries. These preliminary remarks are not only intended to allay, or diminish any feeling of discontent at our impartial preference of the best stock, from whatever country it may have been originally derived, but to encourage our own farmers to take more efficient measures for the amelioration and improvement of our own native breeds. They cannot attend one of our shows, without perceiving the public preference for the new races, and this is a strong confirmation of the justice of the decisions, though we are aware that it is not the least difficult task of the Committee to endeavor to decide without any bias from this clearly pronounced opinion of all the bystanders.

We have said, that the imported stock and their progeny have usually been preferred by the visitors at our shows;—we would make one exception, and that is, with respect to milch cows. Although the milch cows of Great Britain and the Netherlands are in general far, infinitely, superior to our own,—yet during the six years in which I have had this unpleasant duty to perform, I have never seen an imported cow of equal merit (taking the positive evidence of qualities, the quantity and quality of milk into view) with some of our own which have been offered. So fully am I convinced of this truth, as well as that our country possesses a very considerable number of these fine cows, that I am persuaded, that, if Great Britain or the Netherlands were to send us ten cows each, of the best quality, New-England alone could furnish twenty, which would equal them in the quantities of milk, butter and cheese, which they would respectively produce. If this should be true, and I have no doubt of it, we at least possess one of the parent in perfection, from which an improved race might be procured. This opinion is not expressed lightly. We infer its truth from an examination of the products of foreign cows, thought to be so extraordinary as to merit notice in their periodical journals; and during our short period of exhibitions, we have had several, which have equalled the best, of which any accounts have been published. But we would wish, that it should be distinctly understood, that we refer only to a small part of our milch cows, and that we fear much the greater number are lamentably poor. We are well convinced, that some dairies in our country, with two good cows, produce as much as the average of those which have five. If we are correct, or nearly so, in the opinion above expressed, how does it happen that our breed of cattle on the whole is so inferior? Because the owner of a good cow, instead of putting a proper value upon her, will generally

send her to the nearest scrub bull, to save a little labor, and some trifling difference of expense. This we all feel and know to be true. But this shameful negligence is giving place to more judicious measures, owing principally to the effect of the public shows. If every owner of a good, and very superior cow, would consider her in a proper light, not merely as a valuable animal during her life, but as capable of improving his whole stock—if he will spare no moderate expense in procuring calves from her, from bull of an improved breed, we shall soon see our whole stock gradually improve. Bakewell and Princeps, among the most distinguished raisers of stock in Great Britain, lived to see their improvements eminently successful. We are fully aware, that all this exhortation and argument is of very little importance, compared with the more substantial proofs derived from prices.—When, therefore, our farmers learn, that a calf of six months, has been sold at the price of four ordinary cows, of five years old, who have consumed twelve tons of hay, including pasturage, and have required great labor in attending on them; when they hear such a fact as this, that an excellent judge offered fifty dollars for a two months calf, of the cow herein after mentioned, owned by the Hon. Mr. Gray, they produce more conviction than any other sort of address.

Before we announce the premiums, we would express the thanks of the Trustees to these Gentlemen, who without claiming any reward, and purely with the view of giving aid to the show, exhibited fine animals at no small expense and trouble. It is probable that as the Committee took no minutes of these animals some of them may be overlooked. One we could not forget—the fine imported bull Denton, belonging to Stephen Williams, Esq. of Northborough. He has improved with age, and shows that he has an owner who is sensible of his great value. Nor could any one overlook Coelebs, owned by Major Jaques, of Charlestown. If there had not been any other animals on the ground, those who are fond of viewing fine natural productions, would feel that a visit to Brighton was well repaid by the sight and comparison of these animals, differing considerably to be sure, but each very remarkable for beauty. There was also a fine imported cow, with her calf, lately bought by the Hon. Mr. Gray for \$200. Such liberal prices will ensure a constant and gradual improvement of our stock. It is said that this cow is very remarkable for the quantity and quality of her milk—we have heard that she had given in England 30 quarts per day, but there was no person to give us any accurate account of her. Capt. Tracy, of the London Packet, added a new proof, to the many he has already given, of his zeal for the promotion of the Agriculture of his country, by exhibiting three young horned animals, just imported by him. Major Jaques also exhibited three fine cows, without asking a premium.

After so long a trial of the patience of the Competitors, by these introductory remarks, many of which competitors will, however, be disappointed quite as early as they would wish—The Committee awarded the premium:

For the best fat ox, 6 years old, to Oliver Starr, of Deerfield, weighing 2333 pounds	\$40
For the next best do. 6 years old, to Lewis Barnard, of Worcester, weight 2256	30
For the next best do. 5 1-2 years old, to Amos Davis, of Groton, weight 1992	20
For the best bull, to Major S. Jaques, of Charlestown—weight 1243—15 months old	30
For the next best do. to Joshua Coolidge, of Watertown, by <i>Culebs</i> —weight 735—7 months and 4 days old	20
For the best bull calf, to Uriah Manning, of Woburn, being the progeny of <i>Culebs</i>	15
For the next best bull calf, the progeny of <i>Denton</i> , to the Hon. Levi Lincoln, of Worcester	8
For the best milch cow, to John Barr, of Salem	30
For the next best do. to Samuel Morden, of Mil- ton	20
For the next best do. to the Hon. John Welles, of Dorchester	15

As to milch cows, one of the most important, as well as most difficult articles to decide upon, the Committee proceeded, as they will probably hereafter always proceed, solely on evidence as to the *actual* product. The clearer this evidence, the more certain the success. The goodness of a milch cow depends on so many circumstances, and all of them so important, that the Committee are obliged to extend their inquiries very far. Form and beauty is of some moment, but it is also sometimes fallacious; and no one would reject a fine cow, which should give an uncommon quantity of fine milk—butter superior in quantity and quality—continue to give milk every year, till within one week of calving, merely because she had a great head, or a large frame, or small teats, or, in short, because she had not any one of the *fine points* described in the "Complete Grazer." In this, as in every thing else, we must not always trust wholly to the *exterior*.

It has been usual to notice those animals of considerable merit, which deserved attention, but did not obtain premiums. I have never been satisfied with this course. Its tendency is in some degree to lessen the value of the rewards we bestow, if we praise too much those which were not successful; and after all we only shift the mortification, and make it fall with more severity on the greater number whose animals are *not* noticed—but as it is the usage we comply with it. There was a very fat ox presented by Mr. Savary. He was fatter than some of those which obtained the premium, but the difference of age decided the question against him. There were fine bulls offered by Mr. Warren, Mr. Ward, Mr. Rice, Mr. Patch, of the fine native breed, so often noticed by us—and by Mrs. Amory, of the *Culebs* breed, one of which took a premium last year. There was also a superior Holland Bull, imported by Mr. Forrester, offered for exhibition only.

The best bull calf, not noticed in the premium, was Mr. Lee's, of Brooklyn. Maj. Jaques' and Dr. Chapin's. Many others were also very fine.

Of the cows, Capt. Ingle's, of Dorchester, were very remarkable—and also Mr. Brigham's, Job Ranger's and H. Warren's, both of New Braintree—but we have already explained the principles of our decision as to milch cows, which we hope will be satisfactory.

The Committee have endeavored to give general satisfaction, and if they have failed of that, they will at least have the pleasure of having satisfied themselves.

JOHN LOWELL, *Chairman*.

No. II.—On the Smaller Animals.

The Committee of the Massachusetts Society for the Promotion of Agriculture, appointed to decide on all the smaller class of animals including heifers,

REPORT:

That twenty-five animals of the class of "heifers, of from one to three years old," were in the pens for premium or exhibition—all of an excellent quality, and most of them of approved breeds; and generally indicating the increasing attention of the agricultural interest to this important class of stock. The general improvement in this class of animals, compared with our former Cattle Shows, was very marked and decided.

The first premium was awarded for a heifer owned by Henry Rice, Esq. of Marlborough. She was of the breed of "Denton," the celebrated imported bull owned by Stephen Williams, Esq. of Northborough. This heifer was two years old on the first of February, from a cow of the Princeton breed; her form and figure strongly indicative of her size. The heifer sucked only twelve weeks, has had no other keeping than common pasturage and *Meadow hay* in the winter. She calved in May; at six weeks her calf weighed 33 lbs. (the quarter) and never took all her milk until it was five weeks old. This heifer has given from twelve to fourteen quarts of milk during the season.

The second premium was awarded for the heifer owned by Mr. Samuel Brooks, of Brighton, who had also received no extra keep, and was a beautiful sample of the approved Holderness breed, introduced into the state by Gorham Parsons, Esq.

There were other distinguished animals of this class, which deserve particular notice, and were highly approved. Such were that belonging to Mr. Wheeler, of Frammingham, also of the Holderness breed; and those presented by the Hon. Mr. Lincoln, also of the Denton breed, and were animals of beauty and promise.

Five heifers belonging to Hon. Mr. Welles, of his own improved stock, which has on former occasions had distinguished notice by committees of this society.

To these ought to be added the heifer of Mr. Coolidge, and that of Francis Amory, Esq. from Maj. Jaques' imported bull *Culebs*; and also those of Mr. John Breed, of Bellisle, from Mr. Thorndike's bull "Fill Pail," all partaking of the excellent and peculiar qualities of their respective breeds.

The Committee also award for the best Boar,

The first premium to Joseph Rice, of ———, the sum of \$10

The second premium for the best Boar, they awarded to Mr. Spark Vose, of Watertown, the sum of 5

The first premium for the best Store Pigs, they award to Mr. Luke Fiske, of Waltham, the sum of 10

The second premium for the best Store Pigs, they award to Mr. Aaron Dow, of Brookline, the sum of 5

The first premium for the best Merino Ram, they award to Gorham Parsons, Esq.

The committee regret to observe that the general specimen of Merino Sheep exhibited for premium were in their opinion inferior to those of former years. They feel themselves justified only in awarding a second premium for the best Merino Ewes, to Gen. Austin

The second premium for Merino Wethers they award to Francis Amory, Esq.

For Native Wethers there was no competition.—Those presented by Mr. Silas Hall, of Phillips-ton, were very fine animals, and deemed worthy of the first premium, which the committee accordingly award, of 10

[Upon condition that he give evidence according to the rules, that they were wholly bred in this state, and raised by the persons exhibiting them.]

A pair of Stags were presented by Mr. Meriam of Concord, as a specimen of a new mode of altering cattle; and which he represented as easier, equally effectual, and less dangerous than the ordinary method. Your committee were not authorized to grant any premium on this account. Nor can they recommend any to be given, without a more satisfactory evidence of the success of the operation and of all the advantages specified. Should this be the case, at any future time, it will always be in the power, as they doubt not it will be the inclination of the trustees, to grant a just reward for this, as well as for any other successful improvement in the important operations of agriculture.

Mr. Meriam also presented several spayed sows, for the society's premium for animals of that description; but they were not accompanied by any statement of the mode of operation and treatment as required by the rules established by the Trustees, and besides, the operations were very recent, and apparently, some of them at least, done expressly for the exhibition, and for the purpose of offering for the premium. Now in a case of this nature, when a premium is proposed expressly for the purpose of testing the efficacy of an important, and in this country, in some respects, a new operation, your committee apprehend that no premium ought to be granted, unless by well attested experiments, supported by a lapse of time sufficient to leave no question of the result.

Mr. John Baker had entered also four spayed sows, belonging to Gorham Parsons, Esq. for the premium proposed for the same operation. They were in fine health and completely healed—neither disfigured nor weakened by the operation. A certificate also accompanied, made by Gorham Parsons, Esq. which will be laid before the Trustees for their consideration, conformable to their proposal, and in case the same shall be considered, or shall be made satisfactory to them, they in such case award to Mr. Baker the premium of \$20

Samuel Jaques, Esq. also presented for the Society's premium, of the improved Leicester breed of long woolled Sheep, having a cross of the South down, one Ram and six Ewes. They were bought by him in Pennsylvania, and from thence brought into this State. Although your Committee know that the intention of the Society, in the proposal offered in the terms of that premium was, to encourage the importation of the animals from some foreign kingdom or state—and that therefore, strictly speaking, Colonel Jaques would be entitled to no premium on the terms of those proposals; yet your Committee consider the animals are in this State a new and very important race of Sheep, although precisely not of the description proposed, and that Col. Jaques has at considerable expense and trouble, introduced them into it. They, therefore recommend that a premium be granted to him of \$50

The Hon. Thomas H. Perkins, Esq. also presented for exhibition, a Ram and two Ewes of the long woolled Sheep of the Netherlands, the length of whose wool was greatly superior, and its fineness but little inferior, if at all, to those of our present breeds. And although it was not the intention of that distinguished merchant to

stand candidate for any premium, his sole purpose being to aid in the improvement of our breed of Sheep, and thereby to encourage the agriculture and manufactures of his native State, yet your Committee, apprehending that all exertions of this kind, so honorable to the individual, and so advantageous to the community, should receive some mark from our Society of its sense of the benefit conferred on the Commonwealth, they therefore recommend that the Gold Medal of the Society, of the value of fifty dollars, be presented to Mr. Perkins, for this distinguished and successful effort to improve the breed of Sheep in Massachusetts.

JOSIAH QUINCY,
NATHL. INGERSOLL,
THOMAS WILLIAMS,
Noddle's Island.

No. III.—On Manufactures.

Brighton, October 10, 1832.

The Committee on Manufactures award:

- The first premium for Broadcloths, to James Shepherd & Co. of Northampton \$30
The second premium for Broadcloths, to the Wolcott Woollen Manufacturing Co. 20
The first premium for Household Cloth, to Jonathan Mann, of Worcester 12
The second premium for do. to Stephen Buttrick, of Framingham 8
The first premium for superfine Cassimere, to the Wolcott Woollen Manufacturing Co. 15
The second premium for do. to James Shepherd & Co. of Northampton 10
The first premium for Superfine Satinet, to Daniel Ellis & Son, of Walpole 10
The first premium for fine Flannel, to James Howorth, of Andover 10
The first premium for Carpeting, to Sarah Patrick, of Worcester 15
The second premium for do. to Adolphus Bartholomew 7
The first premium for Linen Cloth, to Anna R. Putnam, of Grafton 9
The first premium for Diaper, to Mrs. Putnam 10
The second premium for do. to Susan Young, of Newbury 5
The first premium for Sewing Silk, to Lemuel Healey, of Dudley 5
The second premium for do. to Caroline Bronsdon, of Milton 3

The following gratuities are also awarded:

- To Clarissa Fay, of New Braintree, for a very good specimen of fine Flannel 5
A premium being withheld on account of a deficiency in the number of yards, the Committee recommend the gratuity in consideration of the excellence of the fabric and the importance of the manufacture.—And for the same reasons a gratuity of \$5
To Susan Warren, of Chelmsford, for a piece of Linen of household manufacture.
To George Johnson, of Salem, for a specimen of Duck by machinery of recent invention 10
[This Duck is thought superior to any brought to this market from Europe, and can be afforded at a price advantageous to the purchaser.—The character of the machinery employed, and the quality of the article, afford a hope that duck may become one of our staple articles.]

To Gerry Fairbanks, of Boston, for fine Beaver Hats \$20
[Hats of the same quality are still imported.—The committee have therefore recommended a liberal gratuity in this case, as there is both stock and skill enough in the country to put a stop to the importation.]

At former exhibitions the imitation Leghorn Hats have been of a medium quality; this year there was one specimen from Vermont which was finer than any ever imported. As it was manu-

factured in another State, the committee are not authorized to do more than to commend the excellence of the fabric.

For other specimens of Straw and Grass manufacture, they recommend gratuities as follows:

- To Ann Dalrymple, of Marlborough, for Straw Bonnets \$5
To Miriam Haven, of Hopkinton, for do. 5
To Sally & Eliza Perry, of Brookfield, for a Grass Hat 5
To Betsy Bennet, of Framingham, for an imitation Leghorn Straw 5
To Susan Sherman, of Marlborough, for do. 3
To Mary and Hannah Dobben, of Beverly, for Straw Bonnets 3

Gratuities to the following persons are likewise recommended for their specimens of ingenuity and industry:

- To Fanny Pierce, of New Braintree, for a counterpane and coverlet 5
To Sally Penniman, of do. for a hearth rug 3
To Caroline Fiske, of Waltham, for a counterpane 3
To Susan Stearns, of Waltham, for a knit mantle of cotton yarn 2
To Mchitable R. Dean, of Mansfield, for a hearth rug 3
To Priscilla Cotton, of Plymouth, for a hearth rug 3
To Samuel B. Pope, of Boston, for a specimen of men's boots 5
To Ann Heath, of Roxbury, for a specimen of fine cotton hose 5
To Rebecca Johnson, of Boston, for a hearth rug 3
To Sarah Glover, of Dorchester, for a cotton counterpane 3
To Rhoda Holman, of Bolton, for a fabric of silk weed 2
To Levi Sawyer, of Bolton, for woollen hose 2
To a female of Boston, for very fine hose of merino wool 2
To Sarah Moore, of Brighton, for fine down tippets 2
To Sarah, Polly and Hannah Lewis, for various articles manufactured from Down, and for Artificial Flowers 6
To Nancy Wheeler, of Worcester, for Fans manufactured from feathers 2

Messrs. Barrett, Tileston & Co. of Staten Island, presented for inspection some very handsome Woollen Table Cloths and Silk Handkerchiefs as specimens of their work in the art of Printing and Dying. These deserve mention as highly creditable to the taste and skill of the manufacturers. The Handkerchiefs exhibited were originally striped and crossbared silks. They were shop goods damaged; the original colors were extracted; they were redyed and printed as exhibited.

With respect to the progress of our principal woollen manufactures, the Committee think it may be useful on this occasion to remark, that Flannels of every degree of fineness required for home consumption may be manufactured at reasonable prices with the machinery and skill now in the country. That our best cassimeres are substantial, well made and well finished, and approach nearer to those of first quality made in England, than our best broadcloths do to the best of that country.

That our best Broadcloths are improving progressively with the gain of experience, and faster as respects goodness and the style of finishing than fineness, and there is still room for improvement in the dying and dressing.

There were no extra fine Broadcloths at the exhibition. This may be accounted for without discrediting the manufacturers, by advert- ing to the fact that there is a full demand for cloths of a medium quality, at prices which gave a large profit; the manufacturers are under no inducement therefore to attempt extra fine

cloths. However much it might gratify our pride to see cloths of this description spread before the public at our annual exhibitions, it is neither for the interest of the manufacturer nor of the country, that it should at present be gratified. The best cloths shown at the hall this year, were some pieces from the Litchfield Woollen Factory in Connecticut, offered not for premium, but for exhibition; and these were thought by the Committee deserving of an honorable mention on this occasion. No Cotton Cloths were exhibited; and this among other circumstances may be considered as proof that they require no encouragement beyond that afforded by the present good market.

RICHARD SULLIVAN, } Committee.
WM. LAWRENCE, }

No. IV.—Inventions.

The Committee of the Massachusetts Society for the promotion of Agriculture, to whom were referred the subject of Inventions, REPORT:

That they have had the gratification of inspecting a number of machines connected with the facilitating manufactures and the labors of agriculture, which have been deposited in the society's room, but none coming within the exact terms of their commission, except a Cast Iron Roller, which was duly entered for premium by Aaron Willard, Jr. of Boston. This roller is apparently an improvement on the ordinary roller. It consists of two rollers moving upon one axis, and thereby turns easier and makes less ridges. But the owner not being present nor any person in his behalf, the Committee have not been able to make those inquiries which are necessary to enable them to award any premium.

The next machine presented for their examination and entered for premium, was a Vertical Family Spinner, invented by John Brown, of Providence, and presented for premium by J. R. Newell. It is apparently capable of spinning with from six to twelve spindles, and it was dated to your Committee that a girl of fifteen years of age of common capacity, is capable of tending it; that the thread may be gauged at any number which may be wanted. The size is very compact and takes up a less number of square feet on the floor, than a common spinning wheel. But the Committee had no certificate of its power or evidence of its being used in any family and found to be by experiment capable of facilitating domestic spinning. In their opinion this is the only test of its real utility. They think it a sufficiently simple and ingenious machine. But whether it will perform all that it is promised, your Committee, are for the reason above stated, not able to decide; and the machine not being within any of the specified objects of premium, your Committee do not deem themselves justified in recommending, under these circumstances, any specific premium.

The machine which most attracted the attention of our Committee, was one presented by Joseph Pope, Esq. of Boston, a gentleman long known to the public by his inventions and mechanical ingenuity. This machine is patented; intended to work by hand, in its present model, but easily capable of being enlarged and applied to a horse power.

The material to be threshed, passes through opposite sets of surfaces placed transversely in a frame. They are respectively moving rods;

and constitute a threshing power on an open floor composed of stationary rods.

It was stated to your Committee that it threshed 50 bushels of grain in 12 hours; and 1 bushels and 12 quarts of oats in 1 hour; and that a common sized sheaf passes through it and is completely threshed in 1 minute. The labor is done by two hands, one destined to turn it, the other to feed it, or one man and two boys are sufficient for the same purpose.

In the experiment made before the Committee, it threshed the grain out perfectly. And it is obvious that with a very small expense, it may be converted into a machine for cutting straw without any injury to its threshing power.

Owing to an accident, for which the owner of the machine is not responsible, it was not duly entered, although it was brought to Brighton and deposited in the society's room in proper season for that purpose.

As your Committee consider the machine as likely to be very useful, and as Mr. Pope has been at great expense and trouble for the purpose of bringing it to Brighton, your Committee apprehend that some notice ought to be taken of it, and they therefore recommend that he should have a premium of \$20, he producing the requisite certificates of its being used and approved by a practical farmer.

Mr. Newell also presented for premium, a Corn-Sheller, on a horizontal movement, on a wooden barrel.

The Committee did not see its power, but apprehend it may be made a useful machine, with some improvement, but do not consider themselves authorized in its present state to award a premium.

The same gentleman presented for exhibition a number of excellent and approved English machines, and also some of the invention of this country, among these they notice

An English Turnip Cutter.

Three Double Mould Ploughs.

Batson's Scarifier.

Batson's Cultivator.

Howard's Patent Plough.

Also, an English Hay Maker, sent from Baltimore. All of them are worthy of the attention of gentlemen, interested in improving the agriculture of the country, and their being brought to Brighton for exhibition does great credit to the attention and zeal of Mr. Newell.

A Patent Threshing Machine, invented by —, and also a Patent Hulling or Smut Machine, accompanied by strong and numerous printed recommendations, were presented for the inspection of your Committee, but they had no opportunity to judge of their respective operations.

JOSIAH QUINCY,
CYRUS ALGER,
PAUL MOODY.

No. V.—Working Oxen.

The Committee appointed by the Massachusetts Society for Promoting Agriculture, to decide on the claims for premium for the best *Working Oxen*, at the Cattle show at Brighton, Oct. 10, consisting of John Welles, Silas Gates and Elijah Perry,

REPORT:

That they were well pleased to find amongst the other distinguished evidences of improvement at the show, an increased number of Working Cattle, superior to any previous exhibition.

Twelve yoke of Working Oxen were entered and appeared to contest for the premiums offered by the Society.

The Cattle were in general in their training more perfect, and the committee feel confident that the community may look forward to the most gratifying results.

After taking into view the *strength* in reference to their *age* and *size*, the *equality of match*, the *docility* and *training*, as well as other *general circumstances*, the Committee unanimously agreed to award the following premiums:

To Luther Whitney, of Sutton, first premium	\$30 00
To Peter Darling, of Sutton, second premium	25 00
To John Sherman, of Sutton, third premium	20 00
To Daniel Marble, of Sutton, half of the fourth premium	7 50
To Jonas L. Sibley, of Sutton, the other half of the fourth premium	7 50
To Capt. Joseph Curtis, of Roxbury, the fifth premium	10 00

The Committee were all pleased to see so favorable an illustration of the benefit of the Ox Team, as was generally presented, the use of which cannot but be considered as including the most essential interests of the state.

To the honor of a small but respectable section of the country it receives a principal part of the premiums of the Society. But it is believed that no man will doubt the distinction is well merited. It is to be hoped that other parts of the state will feel excited to such an exertion as will spread the evidences of our farmers care and skill more equally over the state, and thus the great object of the Society in the advancement of the honor and interest of the Commonwealth be promoted.

(Signed) J. WELLES, *Chairman*.

No. VI.—Ploughing Match.

The Committee on the Ploughing Match, consisting of John Prince, Benjamin Goddard, and S. G. Derby, having attended the duty assigned them, beg leave to

REPORT:

That the ground selected for the purpose by the Committee of Arrangements, was a very tough green sward of 20 years lay, and had been chiefly used as pasture for fat cattle, was previously laid off in lots of sixteen rods long and one and a quarter rods wide, making one eighth of an acre, (which was less than was wished, but being the only spot convenient that could be procured, could not admit of their being larger)—the soil excellent and free from stones or trees, and each team had a perfectly equal chance. The ploughs were duly entered for the contest, and the ploughmen drew for lots as follows:

- No. 1.—Aaron Davis Williams, of Roxbury, one pair of oxen, Lewis Bliss ploughman, David Howe driver—Warren's Dedham plough, with wheel and cutter—18 furrows—finished in 34 minutes.
- No. 2.—Jonas L. Sibley, of Sutton, one pair of oxen, Samuel Sibley ploughman, Peter Darling 2d driver—Common Sutton plough, with wheel—17 furrows—23 minutes.
- No. 3.—Stedman Williams, of Roxbury, two pair oxen, Stedman Williams ploughman, Samuel Prince driver—Warren's Dedham plough, with wheel—18 furrows—26 minutes 30 seconds.
- No. 4.—Joseph Curtis, of Roxbury, two pair oxen, Luke Rollins ploughman, Amos Wyman driver—Warren's Dedham plough, with wheel and cutter—20 furrows—27 minutes 30 seconds.
- No. 5.—Luther Whiting, of Sutton, two pair oxen, Royal T. Marble ploughman, Luther Whiting driver—Sutton plough, with wheel—16 furrows—30 min.

No. 6.—Isaac Cook, of Roxbury, one pair oxen, Thomas Howe ploughman and driver—Warren of Dedham plough, with wheel—19 furrows—46 min.

No. 7.—Jas Dudley, of Sutton, two pair oxen, Silas Dudley ploughman, Joseph Dudley driver—Warren of Dedham plough, with wheel and cutter—17 furrows—26 minutes.

No. 8.—Isaac Cook, of Brookline, one pair oxen, Caleb Miller ploughman and driver—Warren of Dedham plough, with wheel and cutter—19 furrows—23 min.

No. 9.—Moses Seaver, of Brighton, one pair oxen, Moses Seaver ploughman, Benjamin Porter driver—Howard of Hingham's plough with wheel—20 furrows—24 minutes.

No. 10.—John Sherman, of Sutton, one pair oxen, Asa Cummings ploughman, John Sherman driver—Sutton plough with wheel—16 furrows—22 minutes.

Previous to the ploughing, it was distinctly stated by the Committee, that the furrow must be not less than 5 1-2 inches deep, and their greatest wish as little to exceed 10 inches in the width of furrow as was possible, and not to hurry their cattle, as they conceived the *best work* could not be performed if over driven—and that goodness of work, together with that of cattle, would be a great object in deciding premiums, as well as cheapness of labor.

They have great pleasure in stating, that the work was well done, and most of it in a superior style, and that those competitors who failed in obtaining premiums, was because the Committee had it in their power to award only three among ten claimants—indeed, they conceive praise is due to all the ploughmen, who discovered great skill in the management of their implements, and the cattle were universally excellent—and in consequence of the request of the Committee that they should not be hurried, they could generally have proceeded in another one eighth of an acre with ease.

The Committee have been unanimous in their awards after a very critical examination, as follows:

1st premium to Isaac Cook	\$20
Caleb Miller, ploughman	10
do. do. driver	5—35
2d premium to Joseph Curtis	12
Luke Rollins, ploughman	6
Amos Wyman, driver	3—21
3d premium to Stedman Williams	8
do. do. ploughman	4
Samuel Prince, driver	2—14
	\$70

All which is submitted.

JOHN PRINCE,
BENJAMIN GODDARD,
SAMUEL G. DERBY.

No. VII.—Agricultural Experiments.

The Committee on Agricultural Experiments, to whom was also committed the inspection of sundry articles of Manufacture, for which premiums were offered,

REPORT:

That five several parcels of Cheese, of more than one year old; and seventeen parcels of new Cheese, were offered for the Society's premiums; which, in the opinion of your committee, are superior to any hitherto exhibited; all made in the town of New Braintree, in the County of Worcester, excepting one parcel of five cheeses, made by Mr. John Ayres, of Oakham, in the same county; of the former, that from the dairy of Capt. John Hunter, was considered to be the richest and best made cheese, and is entitled to the premium of ten dollars; that from the dairy of Capt. Ebenezer Tidd,

the next best, and is entitled to the premium of five dollars. Of the new Cheese, that from the dairy of Mr. William Earl, was considered to be the best, and is entitled to the premium of ten dollars; that from the dairy of Major Roswell Converse, the next best, and is entitled to the premium of five dollars.

Several parcels of fine flavored Butter were also exhibited, uncommonly well made, the buttermilk being more perfectly expressed than usual; that from the dairy of Miss Mary Clark, of Watertown, in the County of Middlesex, was considered to be the best; that from the dairy of Col. Stephen Hastings, of Sterling, in the County of Worcester, the next best—the former is entitled to the premium of ten dollars, and the latter to the premium of five dollars.

For the greatest quantity of Butter and Cheese, made between the 15th day of May, and the 1st day of October, from not less than four cows, the quantity of the Butter and of the Cheese, and the number of cows, to be taken into consideration, Mr. William Earl, of New Braintree, has exhibited sufficient testimony, in the opinion of your committee, to entitle him to the premium of twenty dollars.

Messrs. Brewer & Jordan, of Roxbury, are entitled to the premium of ten dollars, for the best specimen of Sole Leather; for the next best specimen, Messrs. Benjamin Murick & Co. of Roxbury, are entitled to the premium of five dollars.

Five barrels of Flour, from the wheat raised in the present season, on the farm of Gorham Parsons, Esq. in Brighton, and manufactured at the "City Mills," lately erected on the "Western venue," very little inferior in quality to the best made Philadelphia flour, were exhibited by Mr. Benjamin T. Reed, Agent of the Proprietors of said Mills, and are entitled to the premium of twenty-five dollars.

A sample of Starch, in imitation of the Pomme Starch, manufactured by Mr. Robert Jewes, of Boston; and a sample of Mustard, manufactured by Mr. Abraham Beckford, also of Boston, were exhibited—both appeared to be of a very good quality, perhaps equal to any imported; no premiums the present year, for either of these articles, were offered by the Trustees.

The vegetables brought to the Society's Hall very far exceeded in quantity, variety, and size, those exhibited in any former year. The roots of Mangel Wurtzel, sent by Dr. Chaplin of Cambridgeport, were very large, and in great perfection. The Doctor also presented to the Society a very fine Watermelon, from his own arden, which weighed about twenty-three pounds. From the farm of Edward Sparhawk, Esq. of Brighton, some "Silverskin" Onions, uncommonly large. From the garden of Mr. William Ackers, of Brooklyne, some roots of the common red Beet, of an early kind, and of a size seldom equalled. Mr. Josiah Coolidge, of Cambridge, and Mr. Samuel Murdock, of Milton, exhibited some very large Winter Squashes. One from the farm of the former weighed thirty-seven pounds. From the farm of Gen. Hull, in Newton, some Carrots, Ruta Baga, and English Turnips, all of them very large, "taken from a field of two acres, without any cultivation, but what was common to the whole field." From the farm of Capt. N. Ingersoll, of Brooklyne, some Arrak, being a new variety of the

Carrot. From the orchard of Mr. Henry Houghton, in Bolton, in the County of Worcester, some Blue Pearmans, which were supposed to weigh not less than one pound each. From the garden of James White, Esq. in Dorchester, in the County of Norfolk two specimens of the Cotton Plant, which grew in the open air, without particular care; one of which was Sea Island, the other Upland. The pods on both were well filled with Cotton.

From the farm of Capt. Joseph Warren, in Brighton, some ears of Corn, said to be of a very productive kind—"from three stalks ten ears were taken." From the orchard of Col. James Wilder, in Sterling, a very large fine Apple, called "Eve's Apples." From the farm of Dr. Eliakim Morse, in Watertown, some fine ears of the eight and twelve rowed Indian Corn.

By order of the Committee,
THOS. L. WINTHROP, *Chairman.*
October 9th, 1822.

The claims for premiums on Agricultural experiments, will not be decided until the Trustees' Meeting in December; affording time for the competitors to offer the evidence required. The Committee will make an additional Report soon after that period.

BRIGHTON TOASTS.

At the anniversary Dinner, there were a number of good, some complimentary, and a few sparkling Toasts drunk. We have room for a few of them.

The *Coultter* on the land—the *Keel* on the sea—May the first run deep and both run clear: and all who hold the handle or the helm, find honor and reward.

Our mother Earth—May those have the best *share* in her affections, who take the *plough share*.

The world—A great Cattle Show, where the best animals are those who are not *overfleshy* nor *underfed*.

The noblest part of our exhibition—that which is above price, and needs no premium—the Show of New England Yeomany.

By Professor Everett—Colleges, Universities, and Cattle Shows—May all their *puns* do them equal credit.

By Hon. Mr. Quincy—The Presidential Ploughing Match—May the working ox beat the fillies.

By George Blake, Esq.—The American Plough, and the American Prow—May theirs be the victory on the *Plain* as on the *Main*.

The third annual Cattle Show and Exhibition of the Rhode Island Society for the Encouragement of Domestic Industry, was holden at Pawtuxet, on the 16th and 17th of Oct. 1822. In consequence of the premiums being limited to animals raised in the State of Rhode Island, the exhibition of neat cattle was not so great this year as at the last Cattle Show. About 60 individuals were exhibited in the pens, appropriated to neat stock, besides hogs, sheep and horses. Twenty-two premiums were awarded, the highest \$20, and the lowest \$1. The premiums on Agricultural produce will be awarded at the quarterly meeting of the Standing Committee. The committee regretted the want of competition in the articles of Shop Manufactures, but awarded eight premiums. These were for a secretary, blank books, patent steel spring seats, ladies' walking shoes, water loom shuttles, weavers' pickers, ladies' work basket, and short boots. The following articles were recommended, but the committee did not feel authorized to grant premiums, viz.—steel slaies, water proof hats, men's shoes, plough with iron shares, and a cast iron corn-sheller. Among

the Household Manufactures, were counterpanes; a carpet by Mrs. Lydia Hunt, of Pawtuxet, made of grass and rushes; rugs; a beautiful straw hat braided throughout without seam, by Miss Ann C. Green, of Providence; window blinds of rushes, by Miss Sally Eddy, of Providence; a vandyke of milk weed down, by Miss Casey, of East Greenwich; butter; cheese, &c. The ground for ploughing, at the ploughing match, was a well formed green sward, divided into twenty rod lots; three of the lots were ploughed in from 17 minutes 53 seconds, to 19 minutes; and one (the best work,) in 29 minutes.

Abridged from the Providence Journal.

The exhibition of the Rockingham Agricultural Society was made on Wednesday and Thursday of last week at Exeter. It was a subject of regret that the Rev. Mr. Abbot was unable, from severe indisposition, to deliver the annual address. We shall refrain from making any remarks upon the exhibition, until next week, when the official report will be published. It will be sufficient to mention that the manufactured articles were neither so numerous, nor so good as those offered last year, while the show of cattle was, in general, better. It is apparent that there is an increasing attention to the breed of Cattle in this part of the county, and that the general stock of our Farmers is gradually improving.—*Portsmouth Journal.*

The Addison (Vt.) County Cattle Show was holden at Middlebury on the 10th inst. It was attended by a vast concourse, composed chiefly of the most respectable farmers within the precincts of the Society. The specimens of Domestic Manufactures offered for premiums, in number and quality, far surpassed those of any preceding year, and any which have ever been exhibited in this County. A bonnet from the hands of a female in New Haven was shown, so ingeniously wrought as not easily to be distinguished from those imported from Italy; looking glasses from the shop of Mr. Joseph Sargeant, with which the exhibition room was ornamented, were adjudged to be truly ingenious and splendid specimens of the gilder's skill.

The samples of Maple Sugar were exceedingly white and palatable, and evince that with a moderate degree of care in its purification, it would be generally found far preferable to any West India production.

The highest premium for Corn was awarded to Nathan Case, Esq. of Middlebury, for 118 bushels to the acre. The largest number of bushels of Potatoes was found to be 315 from an half acre, cultivated by Mr. Barnabas Chipman, of Shoreham. The cattle and horses for size, beauty, and justness of proportion are seldom to be equalled. Some of the largest male swine that we have ever beheld were brought forward. Notwithstanding the immense importance of raising sheep, and the acknowledged improvements that have recently been made in this branch of rural economy, very few animals of this description were brought into competition.

Upon the whole, this celebration was highly satisfactory to the expectations of the friends of the Society, affording the strongest additional evidence of its increasing utility. Before its formation the farmer was in the habit of culti-

vating acre of land to raise the same number of bushels, which he has now learnt by proper management may be gathered from one, with far less labour and expense. The signal improvements which are apparent in the breeds of domestic animals can scarcely be dated back further than the organization of this Society; And the advances made in home manufactures have been greatly facilitated from the same cause. *Abridged from the Middlebury Paper.*

From the Old Colony Memorial.

The Destructive Worm more particularly investigated.

The worm which has arrested considerable attention in the O. C. Memorial, is no other than the grub-worm hatched from the eggs, of that species of beetle known by the several names of Chafer, Cock-chafer, May-beetle or more commonly May-bug. It is the *scarabæus melolontha* Linnaeus. In Willich's Domestic Encyclopedia will be found the following historical detail of the insect in its several stages. "The May-bug or Cock-chafer has a pair of cases to its wings, of a reddish brown colour, sprinkled with whitish dust, which is easily separated. The necks of these insects are, in some years, covered with a red plate; in others, with a black; but they are distinct varieties. Their fore legs are very short, and thus better calculated for burrowing in the ground, to which they instinctively retreat. Chafers are well known by the buzzing noise they make, in the evening, when rising in the air; but particularly for the irreparable mischief they occasion to the industrious cultivator; having been found, in some seasons, so numerous, as to consume every vegetable production. These pernicious vermin are generated from eggs which the females usually deposit, about six inches deep in the ground. Three months after, the inclosed insects begin to break the shells and crawl forth, in the form of small grubs, or maggots, which feed upon the root, of whatever vegetables they meet with. In this worm state they continue for more than three or four years, devouring the roots of every plant they approach, and burrowing under the ground with the utmost celerity for food. At length they exceed a walnut in size, being large, white, thick maggots, with red heads which are frequently found in newly turned earth, and are much sought after by every species of birds. When largest, they are an inch and a half long, of a whitish yellow colour, with bodies composed of twelve segments, or joints; on each side there are nine breathing holes, and three red feet. The head is larger in proportion to the body, of a reddish colour, with a forceps, or pincer before, and a semi circular lip, with which they cut the roots of plants and suck out their moisture. They have no eyes, but are furnished with two feelers, which serve to direct their motions under ground. At the expiration of four years, these destructive insects prepare to emerge from their subterraneous abode. About the latter end of autumn, the grubs begin to perceive their transformation approaching; when they bury themselves deeper in the earth, sometimes even six feet below the surface, where they form capacious apartments, the walls of which become very smooth and shining, by the exertions of their bodies. Soon after, they begin to shorten themselves, to swell, and burst

their last skin, preparatory to their change into a *chrysalis*. This appears at first to be of a yellowish colour, which gradually heightens, till at length it becomes almost red. Its external figure clearly displays the characters of the future winged insect, all the fore parts being distinctly seen; while, behind, the animal seems as if wrapped in swaddling clothes. In this state, the young cock-chafer, or may-bug, continues for about three months longer; when, towards the beginning of January, the *aurelia* divests itself of all its impediments, and becomes a complete winged insect. But it has not attained its natural health, strength, and appetite; unlike all other insects, which arrive at their state of perfection as soon as they become flies, the cock-chafer continues feeble and sickly. Its colour is much brighter than in the perfect animal; all its parts are soft, and its voracious nature seems suspended. In this state, it is frequently found, and is erroneously supposed by those who are ignorant of its real history, to be an old one, of the former season, which has buried itself during the winter, in order to revisit the sun the ensuing summer. The fact is, the old one never survives the season, but perishes, in the same manner as every other species of insects, from the severity of the cold, during winter.

Towards the latter end of May, these insects burst from the earth, the first mild evening that invites them abroad: after having lived from four to five years under ground. They are then seen to emerge from their close confinement, no longer to live on roots and imbibe only the moisture of the earth, but to choose the sweetest vegetables for their food, and to sip the evening dew. An attentive observer will, at that time of the year, see every pathway strewn with them; and, in warm evenings of May, myriads of them are buzzing along, flapping against every thing that impedes their flight. The heat of the mid-day sun, however, seems to be too powerful for their constitution; they therefore, conceal themselves in clusters, under the foliage of shady trees, but particularly of the willow, which appears to be their most favourite food, and which they seldom quit, till they have consumed all its verdure. In seasons favourable to their propagation, they are seen in an evening, in considerable swarms; their duration, however, is but short, as they never survive the summer. They begin to pair, soon after they have emerged from their subterraneous prison; and the female then carefully bores a hole in the ground, with an instrument for that purpose, with which she is furnished at her tail, and deposits her eggs there generally to the number of sixty. In the year 1751 they were so exceedingly numerous in the county of Norfolk, England, that they destroyed not only all the verdure of the fields, but even the roots of vegetables. Many crops in that country were then almost ruined by the devastations these insects committed, in their worm state; and when they took wing next season, trees and hedges were in many parishes, completely stripped of their leaves. James Ebdon, a Norfolk farmer, made oath, that he gathered *eighty bushels*; but their number did not seem much diminished, except in his fields. Neither the severest frosts in our climate, nor even water, will kill them: as on being exposed to the sun and air, for a few hours, they will recover, and

resume their former lively state. One of the best methods to be adopted for preventing their transformation, is, to plough up the land in the furrows, to employ children to pack them up in baskets, and then strew salt and quick lime on the ground and harrow it in."

It is well known that swine, turkeys, hencrows, and other birds have a high relish for both the may-bug and grub-worm, and whenever opportunity will permit, they will destroy immense numbers of those vermin. But as, conceive, the employment of the hoe would be a more effectual method than has been as yet suggested. During the summer, or autumn, when the grub-worm is feeding on the roots of grass and vegetables, not more than an inch or two below the surface, the task would not be very laborious one to go over the ground with hoes, and destroy every grub that can be discovered. Let a neighborhood of farmers unite their exertions in this service as a pastime, and they may probably enjoy the satisfaction of effecting in some measure, at least, the annihilation of the race, and free themselves for many years from the loss of crops by their devastations. In meadows, or pastures, where the worm has already destroyed the roots of the grass, and the sward, the hoeing may be performed with great facility, and perhaps in some instances it might be deemed useful, at the same time, to hoe in grain or grass seed for a crop. The method of intersecting the fields with ditches, has sometimes been serviceable, in checking a more extensive progress of these worms, as they penetrate through the sides, and fall into the ditch where they may be easily destroyed.

J. T.

Plymouth, Oct. 16, 1822.

N. E. FARMER.

BOSTON:—SATURDAY, OCT. 26, 1822.

Awards at the Brighton Cattle Show.

We have given in this day's paper the whole of the Reports of the several Committees, to whom was entrusted the arduous and delicate task of awarding premiums for animals, manufactures, &c. exhibited at the last Fair, in Brighton. They are worthy of attention not only from those whose feelings or interest are involved in the amicable contest for the prize of agricultural or manufacturing excellence, but of all who have the interests of the husbandman and manufacturer at heart. They will prove useful by pointing out the path which leads to further improvement, and preserved in volumes, from year to year, (as we hope and trust they will be, at least by our subscribers,) will serve as indices to mark the progress of agriculture at the useful arts. Those who may hereafter become candidates for premiums, or disposed to add to the attractions of the "Husbandman's holiday," by voluntary exhibitions of articles or animals, rare, excellent or useful will derive advantages from knowing what has been exhibited, and will find the *Records of the Brighton Cattle Shows* not only curious but useful documents. We think that the judges who have awarded the premiums, by their able Reports, have deserved well of the community; and in bestowing honors and boulties, on those who merited the rewards of skill and industry, have reflected honor upon themselves. Alexander & Bonaparte, in parcelling out kingdoms among their favorite generals, were less honorably well as less usefully employed, than the distributors of premiums at an American Cattle Show.

SMUT IN WHEAT.

Much has been said and written on the subject of smut in wheat, and the different diseases, in grain, which among farmers in general are known by that name. Distinctions are made by scientific writers between smut and burnt grain, which we shall not undertake at present to point out, as both kinds of disorder are prevented or cured we believe by the same treatment.

The following rules will be of use. They are taken in substance from an Essay published in the Massachusetts Agricultural Repository, vol. v, p. 134.

1. Wheat is not to be sown on ground which has born smutty wheat in the year preceding. This would be bad policy if smut were out of the question, as two white crops should never succeed each other, which is against the rules of rotation in husbandry.

2. Manure tainted with smut should not be used for wheat land, unless it is made into a compost, in which lime is an ingredient.

3. When manure is used it should not be spread too thickly, but as evenly as possible.

4. Pure seed should not be left within the reach of infectious materials. This caution extends not only to avoiding the use of a threshing floor employed for smutty wheat; but that of tainted sacks, casks, and vessels for measuring wheat.

5. Wheat should be sowed early that the crop may ripen early, and it should not be kept back by feeding in the spring.

6. The seed should be of a good quality, not light, unripe, mouldy, bruised, or worm eaten.

7. None but good land should be employed in raising wheat, and land which admits of early crops.

8. Wheat should not be sown in very wet weather, even when the soil is dry.

9. A change of seed is recommended by writers on this subject, and few who are wise will procure worse seed to sow than that which they possess already.

10. The purest portions of the plants in a crop should be set apart for seed; and when ripe, these plants should be harvested by themselves, and the seed preserved apart in a safe place. This rule will commonly prove more important than the one preceding.

11. The thick sowing of wheat is improper, for the double reason, that it produces feeble plants, and dampness, both of which encourage smut.

12. No favorable moment for sowing is to be lost, nor is any unfavorable moment to be adopted from a supposed necessity of paying attention to the state of the moon.

The following receipt for preparing seed wheat, so as to secure it against smut, so far as smut depends on the seed, was published in France by M. Gille more than sixty years ago, and is recommended by Du Hamel.

If the seed be spotted it should first be washed in several clear waters, till the black spots disappear. It is then to be steeped in the liquor immediately to be mentioned.

If the seed be not spotted, it is merely to be soaked in the following liquor: make some ley, by putting four pints of water to every pound of wood-ashes, according to the quantity wanted. If to 100 pounds of ashes, 400 pints (or 50 gallons) of water be added, the produce, when strained, will be 20 gallons of ley; to which must be added 15 pounds of quick lime. This will prepare nearly 17 bushels of wheat for sowing.

This liquor when wanted for use must be made as hot as the naked hand can bear it, and placed in a large tub. The seed being put in baskets, must now be plunged into it, and stirred with a stick; after which the liquor must be drained away. The seed

must next be laid on a floor, till dry enough to be sowed. If stirred from time to time with a shovel, to prevent its heating, it may be kept without damage for a month or even a year.

An English writer directs that "after the wheat is taken out of the pickling tub and laid on the floor, it should be well dusted over, and mixed with quick or caustic lime; and if turned over with a shovel, or stirred about with the teeth of a rake, it will dry faster and be sooner ready for sowing, and if run through a barley or oat riddle it will separate better as it is sown.

Another mode of pickling is sometimes practised with success, by immersing the wheat into or sprinkling it over with stale chamber-ley, and afterwards dusting it over with quick lime. But there is danger of the wheat being injured by the strength of the chamber-ley; and the wheat pickled in this manner must be sown immediately after it is dressed, let the state of the weather be what it may; for if kept out of ground for a time its vegetative powers would be destroyed.

A Vermont Farmer has given us the following as his mode of preparing seed wheat:—I take three quarts of slacked lime,* to each bushel of wheat, put them into a barrel, a layer of wheat and a layer of lime alternately; then pour in water till it is all covered. In this situation let it stand from two to four days, as the case may require, [probably according to the temperature of the weather] and the morning before sowing the wheat tap the barrel and draw off the liquor.

Sir John Sinclair advises that "when the seed wheat is put into any liquid it should be run very gently thro' a riddle, when not only the smut balls, but the imperfect grains and the seeds of weeds will float and may be skimmed off at pleasure, which is not the case when the seed is put hastily into the water. The same water should never be used but once in washing wheat, even when brine is employed, it is safest to have fresh liquor for each parcel. Lime is not only of service to dry the seed, but by its caustic and anti-septic qualities, it tends to destroy putridity, and animalcule of every description."

In Young's Annals, vol. x, p. 231, are given the following experiments:

"December 7, 1787. Sowed fourteen beds with the same wheat seed, as black with the smut as ever I saw any.

1. Sown dry, nothing done to it, had	377	smutty ears.
2. Washed well in clean water, had	325	do.
3. Washed in lime water, had	43	do.
4. Washed in a lie of wood ashes, had	31	do.
5. Washed in arsenic and salt mixture, had	23	do.
6. Steeped in lime water four hours, had	12	do.
7. Steeped in lye four hours, had	3	do.
8. Steeped in arsenic four hours, had	1	do.
9. Steeped in lime water 12 hours, had	6	do.
10. Steeped in lie twelve hours, had	0	do.
11. Steeped in arsenic 12 hours, had	4	do.
12. Steeped in lime water 24 hours, had	0	do.
13. Steeped in lie 24 hours, had	0	do.
14. Steeped in arsenic 24 hours, had	5	do.

* Probably by "slacked lime" is not meant that which has become in any degree mild or effete, but lime which is taken from the kiln and brought by the application of water to a powdered state, and what is called by chemists Hydrate of Lime.

Prodigious Pear.—A pear grew this season in the garden of Jonathan Edmunds, in Framingham, which weighed THIRTY FOUR ounces.

The Greeks Victorious.—translations from the Paris Constitutionnel of the 12th September, published in the Philadelphia National Gazette, give accounts of great victories gained by the Greeks over the Turks. The latter were defeated with great slaughter at Thermopylae, and at Trachis on the 20th of July, and the 6th and 7th of August.

Premium Hats.—The fine Beaver Hats, for which a premium of \$20 was awarded to Gerry Fairbanks, at the late Brighton Show, were manufactured by Mess. Dikeman & Shepard of Northampton.

Sweet Potatoes.—The New-Haven Journal states that a number of sweet potatoes was raised in a garden in that city the past season, among which was one weighing 3 lb. 2 oz.

Great Apple.—We have seen an Apple, which grew on the farm of Mr. James Field, of Chester, weighing 22 1-2 ounces and measuring 14 1-2 inches in circumference.

Bellevue Falls Intelligence.

American Manufactures.—General McClure made a bet of \$50, that he would take wool on the fleece and manufacture a suit of satinest cloth in ten hours. The bet was decided last Saturday in his favour, having completed the suit and put them on in eight hours and 45 minutes. The colour was a blue mixture; the wool was coloured in 35 minutes; carded, spun and woven in two hours and twenty-five minutes, fulled, knapped, dried, sheared and dressed in one hour and 56 minutes; carried in four minutes, three-quarters of a mile to Mr. Gilmore's tailor shop, who with the assistance of seven hands completed the coat, jacket and overalls, in three hours and 49 minutes; there was a half a yard of the cloth left, being in the whole 3 and a half yards, and of such quality as was estimated to be worth one dollar per yard. The General offers to double the bet that he will make a better suit in less than eight hours—and dares the advocates of John Bull's manufactures to take him up.

There was a great collection of people assembled on the occasion; Col. Barnard, with the officers commissioned and non commissioned, of his regiment, a full band of music, and many citizens escorted the General from the village to the factory, when after partaking of this worthy citizen's usual liberality, the procession returned to the village, the air resounding with many hearty cheers.—*Steuben and Allegany Patriot.*

The fall meeting of the Susquehanna Agricultural Society was held on the 9th inst. The premium for the greatest quantity of domestic manufactures produced in one family, was awarded to W. C. Threll. His household have made upwards of sixteen hundred yards of different kinds of cloth, besides stockings and yarn sold. Sophia Rice received the premium for the best American Leghorn Grass Bonnet.—*Phil. Union.*

BROWN'S PATENT VERTICAL FAMILY SPINNER.

FOR SALE, at the Agricultural Warehouse, in Chambers No. 20, Merchant's Row, (opposite the East end of the Old Market)—a number of

Brown's Patent Family Wool Spinners,

which are found on trial to be one of the most useful domestic implements that have ever been invented for that purpose, being of so simple and easy construction that a girl of the age of 15 can well do the work of six persons in spinning, and so compact in its form as not to require so much space as a common family spinning wheel. The advantage of this machine over and above the common mode of family spinning, is at once tested in a few minutes operation with the machine; it at once discovers its immense saving of labor, its accuracy in spinning a good thread, and the quantity it will spin. It requires no further examination to judge of its utility than to see it operate. It is afforded at so low a price as to bring it in common use to every practical farmer, and is well calculated for the employment of the inmates of our common town's poor houses.—Any number of Machines can be furnished at the shortest notice, and warranted. Oct. 26.

From the Baltimore Morning Chronicle.

MR. ALLEN—When the recollections of childhood, its companions, cares and pleasures, come over the mind, they act on the imagination, as the soft, hazy, voluptuous atmosphere of an Italian sky does upon the corporeal faculties of man;—they soothe our most agitated moments, and, like oil poured upon the waves of a troubled ocean, they calm the tumult of the passions. I felt the force of these remarks very strongly, a few days since, and my feelings embodied themselves in the following lines, to a well known air.

When first in childhood's happy years,
Life pleasure knew decline,
We wonder'd why the old shed tears
For Auld Lang Syne.

The future then, was spread with flowers,
Joy's sun did brightly shine,
And we thought not then of former hours
Of Auld Lang Syne.

Too young to know the pangs of life,
No woe could we repine;
For we wept no hours with trouble rife
In Auld Lang Syne.

And now, when clouds have dimm'd our day,
When sorrows made us pine;
We cheer the gloom with a glimmering ray
Of Auld Lang Syne.

'Tis a sun bright spot on "life's dark stream,"
Which guilty e'er shall shine,
And our happiest hour, is our longest dream
Of Auld Lang Syne.

Then fare thee well, 'till next we meet,
Affection wot decline;
And we'll talk, when then we fondly greet,
Of Auld Lang Syne.

Baltimore, Oct. 2d.

WIZZARD & Co.

From the Charleston (S. C.) Courier.

To the Agricultural Society of South Carolina.

GENTLEMEN,

The following remarks from the recently published "Travels in New England, by President DWIGHT," (vol. 2, p. 92,) seem to be particularly interesting at the present time. If this valuable Beach Grass could be introduced into our state, there is no reason to doubt that it would flourish on our sea-coast; and it might, under the Divine blessing, at such places as Sullivan's Island, be the means of saving many valuable lives. It would be an object, too, of no small importance to prevent the farther diminution of those salubrious retreats. There could be no difficulty in procuring from Cape Cod, a sufficient quantity of the Grass Plants to make a fair experiment.

T.

N. B.—Would not the Agricultural Society of Massachusetts, if applied to by our Society, furnish the Plants for an experiment?

BEACH GRASS—ITS UTILITY.

"On the dryest and most barren of these grounds grows a Plant, which I had never before seen, known here by the name of Beach Grass. This vegetable bears a general resemblance to sedge; but is of a light bluish-green, and of a coarse appearance. On these sands, sterile as they appear, it flourishes with a strong and rapid vegetation; and, I believe, not at all, or very rarely, on any other ground: and here one would naturally think nothing could grow."

"From a Mr. Collins, now an inhabitant of Plymouth, and formerly of Truro, I received the following information:

"When he lived at Truro, the inhabitants were, under the authority of law, regularly warned in the month of April (yearly) to plant Beach Grass, as in other towns of New-England they are warned to repair Highways. You will observe, that it was required by the laws of the State, and under the proper penalties for disobedience—being as regular a public tax as

any other. The people, therefore, generally attended, and performed the labor. The Grass was dug in bunches, in which it naturally grows; and each bunch divided into a number of smaller ones. These were set out in the sand at distances of three feet. After one row was set, others were placed behind it in such a manner as to shut up the interstices, or, as a carpenter would say, so as to break the joints. It was placed in this manner, in order to prevent the wind from having an open course through the Grass in any direction, lest it should drive the sand away. When it is once set, it grows of course, and spreads with rapidity. Every bunch enlarges, and, with its seeds, plants new ones around it. The seeds are so heavy that they bend the heads of the Grass, and, when ripe, drop directly down by its side, where they immediately vegetate. Thus, in a short time, the ground is covered. *Where this covering is found none of the sand is blown.* On the contrary, it is accumulated and raised continually as snow gathers and rises among bushes or branches of trees, cut and spread upon the earth. Nor does the Grass merely defend the surface on which it is planted, but rises as that rises, by new accumulations; and always overtops the sand, however high that may be raised by the wind.

"Within the memory of my informant, the sea broke over the beach which connects Truro with Provincetown, (the eastern end of which for three miles, is within the limits of the former township,) and swept the body of it away for some distance. The Beach Grass was immediately planted on the spot; in consequence of which the beach was again raised to a sufficient height, and in various places into hills.

"The wisdom and goodness of the Creator, exhibited in the formation of this plant, in this place, certainly claim the admiration and gratitude of man. But for this single, unsightly vegetable, the slender barrier which here has so long resisted the ravages of the ocean, had not improbably been long since washed away. In the ruins, Province Town and its most useful harbor must have been lost; and the relief which the harbor and the inhabitants furnish to multitudes of vessels in distress, and which no other place or people could possibly furnish, must have been prevented. No other plant grows on this sand. The purpose for which it seems to have been created, it answers easily, permanently and perfectly. Perhaps at some period, at a more advanced state of knowledge, when war shall have become less, and the advancement of happiness more, the object of human pursuit, uses of similar importance may be found for most, possibly for all, other objects—however useless they may be thought at present, and however neglected in the inquiries of man."

✍ The Editor of the New England Farmer will be much obliged to any friend or correspondent who will be so good as to furnish information relative to the above mentioned kind of Grass.

JOHN HANCOCK.

During the siege at Boston, General Washington consulted Congress upon the propriety of bombarding the town of Boston. Mr. Hancock was then President of Congress. After Gen. Washington's letter was read, a solemn silence ensued. This was broken by a member making a motion that the House should resolve itself into a Committee of the whole, in order that

Mr. Hancock might give his opinion upon the important subject, as he was deeply interested in having all his estate in Boston. After he had left the chair, he addressed the Chairman of the Committee of the whole in the following words: "It is true, Sir, nearly all the property I have in the world is in houses and other real estate in the town of Boston; but if the expulsion of the British army from it, and the liberties of our country require their being burnt to ashes, *issue the orders for that purpose immediately.*"

The Southern papers have announced "another" and "another act" of the Cumming and McDuffie farce. We hope that when the farce is over, these Falstaffs of the age will be permitted to retire from the stage of public life in the full enjoyment of that sovereign contempt of the American public, which they so eminently deserve.—Patriot.

No. 14.

DISEASE OF CATTLE.

Report on a disease afflicting Neat Cattle, in Burton, (N. H.) read before the New Hampshire Medical Society, June, 1822; by JAMES F. DANA, M. D. Prof. Chymistry, Mineralogy, &c. Dartmouth College.

At the last meeting of the Society, I had the honour to be appointed to visit the town of Burton in this State, and inquire into the causes of a disease to which neat cattle are there subjected; and I have now the pleasure of submitting to the Society the result of the observations which have been made in consequence of this appointment.

That part of the town in which the disease is most prevalent, is surrounded by lofty hills and mountains; the highest part of which is a very elevated point, called *Corway-peak mount*, and is visible from a great extent of country. The predominant rock of which these hills are composed is Granite—a soft decomposing variety in which the crystals and grains of feldspar, are very large and are suffering a rapid decomposition, by which the whole is disintegrated and broken down. The loose stones consist principally of rolled masses of granite, quartz, feldspar, and some specimens of hornstone; a bed of bog ore of iron is also found here. The soil of this place is fertile, and is such as we should expect to be produced by the decomposition and disintegration of Granite rocks, viz. a sandy loam mixed occasionally with coarse gravel. No peculiar appearances were noticed in the vegetation; the usual crops raised by the farmer, grow in Burton as in other places under a similar culture and management: and probably the town would be a flourishing agricultural place if neat cattle could be kept and raised there. The fact is sufficiently established that young neat cattle cannot be raised there, and that cows and oxen cannot be kept there for a number of years without being afflicted with a singular and fatal disease; and it is not a little remarkable, that horses and swine have never been attacked by the complaint. Cattle are more liable to the disease at some seasons of the year than at others, and are usually attacked by it at the close of winter. The symptom which marks its commencement and progress, is a loss of appetite; the animals refuse hay, grain, and salt; they become feeble and much emaciated; and obstinate costiveness accompanies the disease, but the abdomen becomes smaller than in health; the abdominal muscles are contracted towards the spine, and the whole abdomen is diminished to one third of its original bulk. After these symptoms have continued an indefinite time, a brisk *scouring* comes on, and the animals fall away and die. For this complaint, which is very general among those cattle which have remained two or three years in the place, no remedy has been used by the inhabitants with marked benefit and uniform success; the cattle recover only by driving them away to some other place. A satisfactory cause for the disease has not yet been ascertained, and consequently a rational mode of cure has never been adopted. Neglecting the romantic and idle tale of the dy-

ing curse pronounced on this place by a murdered Indian, we are to search for the cause of the disease in the food which the cattle eat, or in the water which they drink.

The fact that cattle are seized with the disease late in the winter seems to point to the food as a source of the evil; and it is well known that certain plants have proved prejudicial and fatal to cattle. The *cicuta virosa*, or water hemlock, was found by Linnæus to be the cause of a disease afflicting the cattle in Norway; and here goats and swine were exempted from the disease; but this plant was not observed in Burton, nor was any other vegetable discovered here which does not grow in other places in the same latitude; and hence we do not believe that the disease is caused by the food. In confirmation of this opinion, I may adduce the fact that the hay produced in this place, causes no disease in cattle which are kept on it in the neighboring towns; whereas hay which is brought from other places into Burton, does not appear to prevent the complaint.

It has been sarcastically suggested, that cattle died at Burton because there was not a sufficient quantity of hay produced there to keep them; but this suggestion appears to be as unjust as it is ungenerous. Hay is produced in such quantities as to be more than sufficient for the cattle. The result of my inquiries on this subject is, that there is a sufficient quantity of hay produced there for the use of all the stock, but that it does not contain any vegetable substance which is prejudicial to the cattle, and which may be considered as a source of the disease.

The examination of the water from various places in Burton offers a more satisfactory result; but there are no external marks which indicate that the water is unhealthy—no sediment is found, no incrustations appear on the sides of the rivulets and springs; but on the contrary the water is clear,* transparent and colorless, and of a pleasant taste. From such properties, I despaired of detecting any substances in it by the application of chymical agents, but was happily disappointed on making the examination. A portion of water from a brook, to which the cattle have free access, was first examined. *Tincture of soap* produced cloudiness; *oxalate of ammonia* produced a slight cloudiness; and *nitrate of silver* produced a similar effect.—No change occurred on the addition of *Barytic water*, solution of *Prussiate of potash*, or *tincture of galls*, or of *turmeric*. It follows from the action of these agents that the brook water, unlike the water of most brooks, is an *hard* water and contains some saline body.—From the action of *oxalate of ammonia*, we infer the existence of lime; and *nitrate of silver* proves the existence of *murietic acid*; the water is then a weak solution of *muriate of lime*. Having ascertained the existence of minute portions of *muriate of lime* in brook water, an examination was made of the water procured from other sources; and

water from *seven* other places, remote from each other and from the brook abovementioned, was examined, and the same effect was produced by the same agents. The effect was more perceptible in some instances than in others, and usually greater in water from *wells* than in that from other sources. The water from two wells in particular afforded abundant precipitates with the *oxalate of ammonia* and *nitrate of silver*. The only beast laboring under the disease while I was at Burton, drank daily from one of these wells.

The continued use of a weak and very dilute solution of *muriate of lime*, may from its known properties, produce the effect now ascribed to it, and be the cause of the disease. *Muriate of lime*, it is well known, is employed as a medicine, and, like other saline medicine, acts more powerfully on the general system in *small doses largely diluted*, than in greater quantities, and in a more concentrated state. In some diseases of the glands, it is said to have been employed with advantage, and when first administered, improves the appetite and general strength. The latter effect is very evidently produced on cattle when first pastured in this town. If previously thin and emaciated, they speedily become fat and appear better than cattle ordinarily do, during the first season they are pastured in Burton.

It may with propriety be asked, why *horses* and *hogs* escape the disease, if it is produced by the water? A satisfactory answer is derived from the fact that horses are not suffered to remain a long time at home; they are continually absent on journeys, and probably in most instances take as much water from other sources as they do from the wells and springs on the farms to which they belong. Hogs take but small quantities of water, and from the mixed and heterogeneous kinds of food given to them, they must frequently take such saline substances as will counteract the effects produced by the minute portions of *muriate of lime*.

If the disease arises, as is supposed, from the saline contents of the water, we can easily explain the fact that its attacks are most frequent in the winter. It is then that they usually receive water from wells, which are proved by experiment to be most strongly impregnated; and then also springs are generally low and consequently contain more saline matter: nor does the food in winter tend to counteract the effect of the water, by keeping the bowels lax, which is a well known effect produced by summer and spring food.

The disease, to which the cattle in Burton are thus subjected, has been a great obstacle to the prosperity of the town; and it will probably continue to have this effect, although without doubt it may be prevented by proper attention and management. Some persons, residing in Burton, have for several years past given to their cattle during the winter season, a certain kind of *mud*, and, as they affirm, with some benefit. This mud is found on a meadow, and during the summer, it is collected for use; it is made into balls as large as an ordinary potatoe, and forced down the animal's throat; by it the

* It is a common remark that the waters of Burton are remarkably clear; probably their refractive density is increased by the saline matter they contain.

tonic effect of the muriate of lime is prevented, and the bowels are kept lax. I visited the spot where the mud is procured.—A spring issues from the place and the water brings with it a greyish white matter which is deposited in the rill leading from the spring. This whitish substance is the matter in question. After being heated to redness it becomes snow white; when digested in an acid, a slight effervescence occurs, a portion is dissolved, and the remainder has the character of fine white silicious sand; the portion dissolved in the acid was found by appropriate tests to be *carbonate of lime*. The effect of this substance cannot be explained on chymical principles, and doubtless depends on the general principles, of the effect of laxatives in counteracting the actions of tonics.

Having embraced the idea that this disease arises from the small portion of muriate of lime dissolved in the water, I recommended to a number of the inhabitants who were assembled for the purpose of assisting me in my inquiries, to make use of *weak ley*, or *ashes*, or *soap suds*, as a remedy, or rather as preventives. Either of these substances, from the carbonate of potash they contain, will decompose the muriate of lime, and carbonate of lime and muriate of potash will result from such decomposition. Now both these substances, if not quite inert in the small quantities in which they would be produced, will act as purgatives; and as a confirmation of the general principles advanced in this paper, I was informed, on recommending *soap suds*, that the only cow which was ever raised in Burton and escaped the disease, was in the habit of frequently drinking soap suds from the tubs which contained it; and that it was consequently left for her use after family washings. It is not a little remarkable that the inhabitants did not avail themselves of the information to be derived from this hint.

A person who formerly lived in Burton brought water from a spring situated at a distance from his house, for the use of his cattle, and they were found to thrive much more, and with greater certainty to escape the disease. Why he was induced to use this water I know not; but on examination by re-agents, it gave indications of containing *very small* quantities of muriate of lime; much less quantity indeed, than in any other water submitted to examination.

These facts and observations are now submitted to the Society, with the hope that the investigation, conducted under their auspices, may not prove wholly uninteresting and useless.

ALBANY COUNTY AGRICULTURAL TRACTS.

By the politeness of J. BUEL, Esq. we have received a pamphlet, with the above title, containing much valuable matter, calculated to aid the American Farmer in the principal and staple concern of all civilized societies. The pamphlet is published by the Executive Committee of the Albany County Agricultural Society, who have "resolved to publish, annually, a pamphlet of about 48 pages, to be distributed at their annual fairs, among the members of the Society. It is believed," they observe further, "that this will essentially aid the progress of agricultural improvement; and as practical information is to be preferred, communications of this kind are respectfully requested for the subsequent numbers. They may be addressed to J. BUEL, Corresponding Secretary. The work will be so pagged and arranged that six numbers will form a volume of 288 octavo pages."

The articles which compose the first number consist partly of original matter, and in part of judicious selections. We shall, from time to time, give such extracts, notices and abridgments of the work as we believe will be most beneficial to our readers, and best comport with the patriotic and philanthropic views of the publishers.

ON THE CULTURE OF TURNIPS.

Sands and sand loams are peculiarly adapted to the culture of this root. The county of Norfolk, which is one of the most improved agricultural districts in England, has acquired its high reputation, in a measure, by its turnip crops. Cattle are winter fattened upon them invariably, with the aid of straw, or sometimes a little hay. The soil of that county was very similar, originally, to the pine district between the Cahoes and Coeymans. But our hard winters prevent our using this root with English economy. There they are left in the field, and drawn daily as they are wanted. Here they must be housed or buried, before the frosts set in. Notwithstanding this objection, I am satisfied, from four years' experience, that they may be cultivated by us with great profit, as a *cattle food*, particularly the Swedish sort, or *ruta бага*.

The flat turnip, of which the green and red top are varieties, is raised with very little trouble, and with me have been invariably a second crop. I have sown them after wheat, rye, peas, and flax, with a single ploughing, with and without manure, with uniform success. I have sown from the 20th July to the 10th Aug. broadcast, at the rate of one pound of seed to the acre—generally hoed them once; and the medium crop has been about 200 bushels per acre. *The later turnips are grown, the better they are for the table.*

The *ruta бага* requires more labour in raising, and better compeasates for it. I plough twice and harrow; about the 1st July, the ground is thrown into three feet ridges, by turning two furrows back to back. The manure is then drawn out, and thrown with a shovel into the furrows, about six rows being dunged at a time. The manure is covered, by reversing the ridges, as soon as practicable; and when the whole field is finished, a light one horse roller is passed over lengthwise, which flattens the ridges and pulverises the lumps. The seed is then immediately dibbled in one foot apart. A man will make the holes, and two boys, of 10 or 12 years old, will drop the seed, and cover two acres a day. One to four seeds are put into each hole. I prefer the dibble to the drill, on account of the greater facility of clearing the crop, and because a dibble can be made in two hours by any farmer, and consequently costs nothing. When the plants are well up, I pass the cultivator between the rows, and hand hoe the ridges, for which the skim hoe is far preferable to the common hoe. If the ground is not very foul, they are as easily hoed as an equal quantity of Indian corn. As soon as the roots are as large as a goose quill, I thin them so as to leave but one plant in a place, and fill up vacancies by transplanting. After this, the cultivator is passed through them once or twice, and the weeds, if any, on the ridges, taken out with a hoe or the hand. The product has been from 400 to 600 bushels. To preserve the roots, dig about one foot deep upon the side of a hill, leaving the bottom inclining, and suffi-

ciently broad each way to be able to pile in the space, in the form of a cone, 100 bushels. Place the roots in it, and bring the top to a point as far as practicable. Cover with straw, and then dirt. They will bear considerable frost without injury. Take care to dig a trench round the mound to turn off the water. In March, or perhaps February, you may break through the frost, and take out roots, lay them on your barn floors, and cover them with hay or straw; from whence they may be fed to cattle.

The *ruta бага* is fed without cutting, to neat cattle—a bushel a day, without straw, is enough for a milch cow. To fat cattle, they may be given in greater quantity, though never so many as to occasion a continual looseness. Hogs will feed and fatten on them; cut small, they are remarkably fitted to fatten sheep; and the horse, once accustomed to them, will prefer them, to his grain. For all animals, they are improved by steaming or boiling. In the north of England, it has been stated, that stage horses are kept upon steamed *ruta бага*, without grain. A gentleman in Dutchess wintered more than fifty hogs upon them thus prepared, and the swine did well.

My experience with the globe and Scotch yellow turnips, is not sufficient to enable me to speak satisfactorily of their culture; but I have both kinds growing luxuriantly.

J. BUEL.

J. ALEXANDER, Esq.
Sec'y of Albany Co. Ag. Society.

ON THE CULTURE OF MILLET.

Millet is cultivated both for grain and fodder. If exclusively for the latter, it is cut as soon as it attains its growth, before the grain begins to ripen; if for both, as soon as the major part of the seed is ripe,—otherwise the birds will eat and waste a great portion of it. The stock and leaves remain green and succulent, even when the seed is all ripe. The best way to harvest the crop is, to cut it with a sickle or cradle; and as soon as it is sufficiently dry, bind it in small bundles, thresh it immediately without unbinding the sheaves, and use the straw for winter fodder. It improves the latter to have it sweat in the mow. The product is from ten to forty bushels in seed, and from one to four tons in fodder, according to the quality and cleanness of the land. The seed is stated, by gentlemen who have made accurate experiments, to be equal to Indian corn for fattening hogs; and the stock or straw is preferred by neat cattle to clover. The objection to this crop is, that it is an encourager of the growth of weeds, from its slow growth in the early stage of its vegetation. The ground should be clean, and in good heart.

I sowed millet this year, at four several times. The first, 23d April, which was harvested about the 1st August: the second, 27th May—harvested 21st August: the third, 1st June—harvested 10th September. The crops were all good. When intended wholly for fodder, I think it may be sown as late as the 10th July. From my experience in two years, I would recommend that the ground be ploughed early, that the seeds of weeds may vegetate; that the ploughing be repeated at intervals, and the crop be sown from the 1st to the 10th June. Cut entirely for fodder, it is a very nutritious

food. Sow from 12 to 16 quarts to the acre, and cover the seed with the harrow.

There are five species of this grain spoken of in the Domestic Encyclopedia, three of which I have had growing in my garden, this year, viz.

1. The *panicum*, or common millet, which is grown extensively in India, and of which it is a native.

2. The *panicum germanicum*, cultivated extensively in Germany and the South of Europe, where it is hulled in mills adapted to the purpose, and thus prepared, is used extensively for puddings, &c. Either of these kinds will do for field culture, and they are believed to be varieties of the same species.

3. The botanic name I have not ascertained, but in common language the third species is called the *chocolate millet*, from the circumstance of its seeds, prepared like coffee, making a beverage similar to chocolate. It grows similar to broom corn, and the grain is black.

J. BUEL.

J. ALEXANDER, Esq.

Sec'y of Albany Co. Ag. Society.

From the Worcester papers of Wednesday.

Believing that an essential improvement might be made in the breed of Swine in this vicinity, I have turned my attention to this object. I have bred from the first quality of our native stock; but have found the produce variant and uncertain in form, size and propensity: some improved, and others deteriorated. I have crossed with more reputable breeds; but did not obtain that fleshy form and disposition to fatten upon light keeping, most valuable to farmers who supply the market, and families who supply themselves.

In 1820, I examined the pens of Mr. John Reed, of Roxbury, who, by the agency of Col. Pickering, had procured a breed from England. As he was raising and fattening upon a large establishment, having, as estimated, 13 tons preparing for market, I had an opportunity of viewing them in their various stages. From their appearance and his account of them, I was satisfied of their excellence, and obtained the kind. They may be seen in possession of Capt. Munroe, Mr. Butman, Maj. Burt, and Mr. Rufus Porter. One of the kind was exhibited at our last Cattle Show by Mr. Gleason, who obtained the first premium.

It being suggested by the Committee on Neat Stock, the last year, that the breed might be improved by crossing with a coarser kind, I wrote to Mr. Reed on the subject, and received the following statement:—"I have often tried the experiment of crossing with a coarser breed of hogs, and as often found my hogs to degenerate; but when I have crossed with small-boned hogs, it has answered well. My hogs are of the Bedford breed, so called in England; and experience has proved, to my satisfaction, that this breed is far the best that has been introduced into our country. They are quiet in their nature, fat easy and with little expense or trouble. I have had some weigh, at 12 months old, about 340 lbs.; and a considerable number, at 18 months old, 400 lbs."

I have distributed two litters of the kind, and have the third now ready for disposal.

O. FISKE.

Worcester, Oct. 28, 1822.

From the American Farmer.

A PLOUGH CLEANER.

Downingtown, Pa. 7th Month 14th, 1822.

Respected Friend,

I have received thy acceptable letter, and really wish that I could add to the merits of thy work, by "frequent mental contributions," as thee desires me to do. But I feel great delicacy in venturing any remarks among the able productions of thy correspondents. And I know so little of the theory of Agriculture, that my observations must necessarily be confined to a few practical matters, such as might occur to any one who has been raised as a plain farmer.

I will, however, now give thee a description and drawing of an appendage to the plough, which I have used for several years, and found very convenient; it is a "plough cleaner." I very recently exhibited the contrivance before the Philadelphia Agricultural Society, and it was approved by their Committee on Implementations.

The staff B, rests towards one end on the coupling round of the plough handles; at the other end it has a mortice, A; to receive the upright E; they are connected by a pin, so as to work like a hinge.

The upright E, is placed three inches before the coulter D, and joined to the beam, C, by a screw bolt, which may be passed through either of the three holes in the upright, so that its range can be adapted to the depth of ploughing.

The front edge of E is made a little circular, to prevent its acting as shears; G represents a circular thin steel spring, screwed on the beam and tied with a string to the staff, B. The whole contrivance is placed on the land side of the plough.

The ploughman, when he wishes to use it, grasps the staff with his left hand, and drawing it backwards causes the lower part of E to advance and rid the coulter of whatever had collected about it. The spring, G, will then restore the upright and staff to their former positions, ready to be used again.

I am with much respect thy friend,

JOSEPH KERSEY.

From the Village Record.

The following communication from Mr. Sharpless, of Downingtown, is worthy of attention. The experiment for the preservation of Peach trees from the worm, we earnestly recommend to those who have the means of trying it; and we shall be obliged by being informed of the effect. We shall also esteem it a favor if any one will give us information how to preserve the Morella cherry from the fly which is so rapidly destroying it. Mr. Sharpless has our thanks for his note; we hope he will continue his observations and give us the result.

Downingtown, Pa. 10th Month 10th, 1822.

Esteemed Friend,

I had observed to a friend, that I thought it a pity that the Peach, which was so highly esteemed in its season for its agreeable flavor as well as wholesomeness, could not be cultivated with that success they formerly were.

He remarked that he had heard of an accidental discovery which had been made to prevent or destroy the worm.

A Fuller who had been colouring cloth with the shells of walnuts—after having extracted the colouring property from them threw them out by the root of a Peach tree which stood near his Mill, it appeared to be on the decline, the consequence was that the tree revived and grew luxuriantly; this induced him to suppose that the shells contained something destructive to the worm, he therefore applied them to other trees with equal success.

As it is now the season for gathering the Walnuts, I have thought it right to communicate this information to the public that the experiment may be made.

I have discovered that the worm which has injured our Peach trees, like the Hessian fly has passed from East to West. I was in the Redstone country 22 years ago, the trees then, had not been injured by them—about 12 years after, was there again, when the trees were almost all destroyed; and for 15 or 20 miles West, beyond that they were fine and flourishing—7 years afterwards passed through the western part of the state into Ohio, found the worms had progressed westwardly as far as Mt. Pleasant, and but a few miles beyond; this was 3 years since, from hence I concluded that the fly which generates the worm moves on a few miles every year. This I think is the case with the insect which has within a few years affected the Morella Cherry trees, which are now nearly all destroyed. The first I saw of their effects on those trees, was in the neighborhood of Germantown, not more than 7 years ago, I think it was 3 years before they reached this part of the country.

From the Providence Journal.

Rhode-Island Silk.—Isaac Barker, Esq. of Middletown, in this state, now in this town, wears a very handsome silk vest, which was wholly produced and manufactured on his own farm. He has made silk for three or four years, commonly about thirty pounds a year, when prepared for spinning, and, we are happy to learn, finds it a profitable business, which he thinks may be extended with ease and advantage. We doubt not, the farmers of the state might easily make enough of this valuable article to supply our own consumption. Thus, one after another, are the resources of our country brought into view, and rendered valuable. The time was, when it was thought hardly practicable to procure a woollen hat, of domestick manufacture. The time may be, when we shall export silk stuffs, as we now export cottons, by bales and cargoes!

An extensive establishment for repressing Cotton is now rising at Mobile. The building is 226 feet in front, by 130 deep. There will be, exclusive of horse presses, a powerful Hydraulic Press, which is calculated to press 270 bales a day. There are to be two fire engines attached to the premises; and four wells will be excavated on the ground. The proprietors of this establishment are Messrs. Lepetre & Townsley. The expense of the undertaking it is calculated will be about 50,000 dollars.

Statesman.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.PROFITABLE AND RESPECTABLE EMPLOYMENT FOR
YOUNG MEN.

Extracted from an "Address of the General Committee of the Board of Agriculture, for the State of New-York, to the Officers and Members of the County Societies."

"To those resolute young men, who, having discovered that there is no longer room for them in the professions and in commerce, and are not afraid to look to the ample bosom of nature for their support, the committee would advise, that, having completed their education (for education is a great protection and solace in the indolent hours of the country) they place themselves with some opulent farmer, for three years, to learn the practical and fundamental principles of his art. These they can learn at his expense, and can repay him for his care by their industry and fidelity. At the expiration of that period they can, if they have a moderate capital to begin with, establish themselves with great prospect of success. Some capital, however, is necessary; to own a bare farm and nothing but that, is only an embarrassment of a different kind; a moderate capital is essential to put it in operation and make it productive. It is the want of that capital which has caused agriculture, as an art, to be so long stationary in this country. The accession of every intelligent family and person to the country is a substantial acquisition. By multiplying and spreading intelligent persons over the face of the state, the condition and happiness of society will be rapidly improved; and experience will teach them, what it has already taught to others, that it is not only possible to be truly contented in the country, but to have no wish for change."

TO PREVENT BEES FROM BEING DESTROYED BY THE
WORM.

Set each corner of the hive on a piece of wood about an inch square and a quarter of an inch in thickness. This elevates the hive a little and prevents the deposits of the eggs which produce the worm, and which are always placed where the edges of the hive come in contact with the bench.—*Amer. Farmer.*

TO PRESERVE CATTLE FROM DISEASE IN THE WINTER.

When cattle are kept out in the winter, it is recommended as a useful practice to rub some tar at the root of the horn, which prevents the wet from getting between the root and the skin, and it is said contributes to preserve the health of the animal, and to keep it free from various diseases to which it may otherwise be liable.

ibid.

AGRICULTURE, COMMERCE AND MANUFACTURES DEPENDENT ON EACH OTHER FOR PROSPERITY.

Extracts from Mr. Law's Address to Prince George's Agricultural Society in Maryland.

"That consumers for our agricultural products should increase with augmenting food, &c. you will acknowledge is most desirable, and that the consumers should be rather at home than abroad, as they must be adding to the wealth of the nation by their products of industry, given in exchange for the products of the soil, will, I trust, be granted; for double industry is thereby obtained, and our country is ren-

dered independent of foreign nations for clothing, furniture, iron mongery, crockery ware, glass, &c.

"An apprehension I am aware is prevalent, that foreign commerce will be diminished by manufacturing for ourselves; but much deliberation makes me conclude that it will increase, as well as the coasting trade. The only truly desirable commerce consists of the exchange of our indigenous products in a raw or manufactured state for the products of foreign climes, and it is evident that we shall bring back more silk, coffee, sugar, tea, spices, wine, &c. as increased industry enables us to export more.

"It is proved by Mr. Colquhoun, that poor rates are heavier in a country merely agricultural, than in one whose inhabitants are merely manufactural. The reason is obvious. When the head of a family is sick or dies, who is a cultivator, his wife and children become paupers; but if he be a manufacturer, his wife and children can be employed in factories. Humanity and patriotism therefore dictate, that a nation ought not to be merely agricultural.

"In sea-port towns manufacturers are particularly desirable, as they support the wives and children of absent sailors. Poverty causes crimes and vices, and I have observed that there were fewer vagabondising boys, and fewer wretches in jails and poor houses, in manufacturing sea ports. The moralist and statesman must therefore be advocates for this last state of society."

In order to make butter in cold weather, it is recommended to pour as much boiling water into the cream as will bring it to the temperature of milk just from the cow. Cream so managed, says a writer in the *American Farmer*, will require very little churning, and no other disadvantage accrues, except that the butter will be white for a day or two.

WASHING RENDERED EASY.

For the use of private families, where linen is dirtied by perspiration or grease, it will be of great service towards rendering it white to steep it for some time in a clear liquor, made by mixing one quart of quick lime in ten gallons of water, letting the mixture stand 24 hours, and then using the clear water, drawn from the lime. After the linen has been steeped in this liquor, it should be washed as usual, but will require much less soap to be used.

Rees Cyclopaedia, art. Bleaching.

WARM WATER FOR COWS.

It has been said that cows will give the more milk in cold weather in consequence of having the water which they drink made a little warm.

MODE OF PRESERVING POTATOES AND FRUIT.

Put the potatoes into barrels, and fill up the numerous crevices with fine sand, which will exclude the air, and preserve them from injury. This method may likewise be applied to apples, pears, &c. If they should be penetrated with frost, they will sustain no injury if the frosty particles are extracted by putting them in cold water.—*English Magazine.*

Boiling corn for hogs is recommended, and there can be no doubt but it will afford more nourishment when cooked, than when raw. It is thought to be best to boil it on the cob, which will add to the nourishment afforded by

the grain. Steaming would doubtless answer the same purpose.—*Plough Boy.*

SPOILED POTATOES.

When it happens that a parcel of potatoes are so far destroyed as to be unfit for food of either man or beast, even after they are reduced to the consistence of soft soap, by frost or wet, there are two ways by which they can be rendered useful, either in the manufacture of nitre, or converted into a rich manure.

To make nitre, beat up the spoiled potatoes with dry quick lime, mixed with ashes from the hearth. Let the mixture be turned over, sprinkled with water, and exposed to the atmospheric air, for the further absorption of azote. The formation of nitre may be ascertained by washing a little of the mixture in water, and moistening therewith a slip of brown paper, which will become match paper when dry, and burn with a force proportionate to the strength of nitre. When sufficiently strong the whole mass can be washed, the liquid boiled down for chrysalization, and the sediments thrown to the dung-hill; or the brine can be used with common salt for the preservation of meat, for pickling wheat, or any other purpose to which saline preparations are generally applied; or will be found particularly useful for washing dirty clothes.—*Minerva.*

WEEPING WILLOW.

A writer in the *American Farmer* has the following observations:—"From a remark I met with many years ago, that 'in Priestley's opinion, the Willow was the greatest absorbent and corrector of bad air,' I have planted them all round that part of my rice field, which is nearest my dwelling and negro settlements.—My people are very healthy, and although I move from hence to Smithville, ten miles down the river, six weeks or two months later than my South Carolina friends do from their rice plantations, and later than any one in the neighborhood of Wilmington, who has a summer residence—and although I visit it almost weekly through the fall, I experience no inconvenience. In my 66th year, I do not recollect having kept my bed a whole day in my life."

PAINTING WALLS TO MATURE FRUIT.

Mr. Daws, of Slough, near Windsor, (Eng.) has made the experiment of painting one half of a wall black that was covered with a vine, and leaving the other half in its common state. That part of the vine which covered the black wall, ripened the grapes earlier, and yielded about three times the weight of fruit that the other produced.—*Pomarium Britannicum.*

CATTLE STALLS.

Extract from Hon. Timothy Pickering's Address to the Essex Agricultural Society.

The common cattle stalls of our country are so ill contrived and so straitened in their dimensions, that the cattle are constrained to lie down, in part, in their own dung. This dries and forms a thick coat on their hind quarters, from which they are not relieved till they shed their hair in the spring. They are thus rendered *uncomfortable*. To be uncomfortable is to suffer some degree of *pain*; and no one will suppose that animals in *pain* can thrive, or preserve their *plight*, with the same food, equally with others perfectly at ease. Even hogs, tho'

come to wallow in the mire, in warm weather, are always pleased with a dry bed, and thrive best when kept clean.

BEST SHAPE FOR CATTLE.

To the question, "What is the shape for feeding well with little food?" Mr. Knight, (a gentleman in England, eminent for his knowledge and accurate observations relative to plants and animals) answers, "The more deep and capacious the chest, and the shorter and lower the animal is, relative to its weight, the better adapted it will be to live and fatten upon little food; the more labor it will also go through; and I have always found the most short legged gen to be the best laborers. Mr. Marshall also observes, in his Rural Economy of Gloucestershire, that the best laboring ox he ever saw, had the shortest legs."—*ibid.*

SWEET APPLES, &c.

"After providing a due proportion of apples for the table, and the ordinary purposes of cookery, I do not hesitate to express my opinion, that for all other uses, sweet apples are entitled the preference. The best cider I ever tasted in this country, was made of sweet apples. They afford also a nourishing food to man and all domestic animals. What furnishes a more delicate repast than a rich sweet apple baked and eaten with milk?—I recollect the observation made to me by an observing farmer, before the American revolution, that nothing would fatten cattle faster than sweet apples. Mentioning this, few years since, to a gentleman of my acquaintance in an adjoining state, he informed me, that he was once advised to give sweet apples to a sick horse. Happening then to have them in plenty, the horse was served with them, and he soon got well: and continuing to be fed with them, he fattened faster than any other horse he had ever owned (and he had owned many) at was fed with any other food.

"Mentioning to the same gentleman, what I had long before heard, that good molasses might be made of sweet apples, he confirmed the fact by an instance within his own knowledge: and he further expressed his opinion, (and I have not known a man whose practical judgement was entitled to more respect) that it would not be difficult, by forming orchards of sweet apples, to supply molasses for the general consumption of the United States. I have never tasted any sweet apple molasses; but I suppose it has not (or has honey) the rich sweet of molasses from the sugar-cane; yet, for family uses in general, it would be a useful substitute for the latter. The process in making it I suppose to be very simple. The apples being ground, and the juice (or cider) expressed, at the cider-mill, it is immediately boiled, (that is, before any fermentation takes place) and the scum being taken off, it rises, the boiling is continued until the liquor acquires the consistence of molasses.

"Sweet apples are of different degrees of sweetness. Those of the richest kinds should be chosen for the purpose of making molasses. In grafting, the cions should be taken (as they ought to be for all kinds of fruit) not from old, worn out trees, but from those whose originals are in full health and vigour. For it has been satisfactorily ascertained in England (and I doubt if it are not wanting in our own country) that fruit trees have their infancy, (springing

from seeds) youth, maturity, and old age; and that when they have reached this last stage, it is in vain that attempts are made to continue them. Or if the cions take, and grow for a few years, they are unproductive, and soon decay. The reason is plain; every cion is a part of the tree from which it is taken; and if this be in a state of decrepitude, so will be the cion; and although grafted on a youthful, thrifty stock, it will be of no avail."—*ibid.*

TO MAKE A PICKLE OR BRINE FOR BEEF.

To eight gallons of water add half a pound of salt petre, one pound of brown sugar, and one quart of molasses, with as much fine salt as will make it float an egg light, taking care that the salt dissolves lest it be too strong—skim it well and it is fit for use.

Your beef or tongues should be put in cold water and remain 24 hours, then drained for an hour or two, previous to being put into the pickle.

Beef tongues, veal, or mutton for smoking should not remain longer in pickle than ten days.

This pickle need not be boiled, (which operation tends to harden the meat) but will remain perfectly sweet till spring, when, after your beef is used or taken out, it will be found the very best in which to cure shad, giving them a delicious flavor, and fine red colour throughout.

This receipt is offered with confidence to the Editor of the Farmer, as one of the very best ever adopted. And it is the opinion of the writer, will answer fully as well for pork, with the exception that the latter should not be soaked in water.—*American Farmer.*

MANNER OF PRESERVING EGGS PERFECTLY FRESH FOR TWELVE MONTHS.

Having provided small casks like oyster barrels, fill them with fresh laid eggs, then pour into each cask, the head being taken out, as much cold thick lime water as will fill up all the void space between the eggs, and likewise completely cover them. The thicker the lime water is the better, provided it will fill up all the interstices, and be liquid on the top of the cask. This done, lay on the head of the cask lightly. No farther care is necessary, than merely to prevent the lime from growing too hard, by adding occasionally a little common water on the surface, should the lime appear to be growing hard, and keeping the casks from heat and frost.

The eggs, when taken out for use, are to be washed from the adhering lime in a little cold water, when they will have the appearance and qualities of fresh laid eggs, the lime preserving them from shrinking or putridity.—*ibid.*

TO PRESERVE HAMS, OR OTHER SMOKED MEAT, THROUGH THE SUMMER.*

Wrap up the meat in tow, of either flax or hemp, after shaking out the loose shives, and pack it in a tierce or barrel, taking care that there be next the tierce and between every piece of meat, a thick layer of tow packed in as close as possible; then set it away in a dry cellar or upper room. It is enough that the

*This has been tried and found to answer well, says the Editor of the Albany County Agricultural Tracts.

barrel or tierce be sufficient to keep the mice out, as no fly or insect will enter the tow.

Tow and flax are such bad conductors of heat, that a piece of ice will be preserved a long time wrapped up in tow. Cut straw also answers extremely well to keep hams in. Ashes are apt to communicate a bad taste to meat. Care should be taken to prevent the flies from having access to the meat before being packed away.—*Archives of Useful Knowledge.*

PRESERVATION OF BUTTER.

One part of loaf sugar, one part refined salt petre, two parts of the best pure salt are to be pulverized together and kept for use; one oz. of this is to be mixed thoroughly with 16 oz. of the butter as soon as it is freed from the butter milk; it is then to be put into a close and perfectly clean dry vessel, from which the air is to be carefully excluded, and it will remain good for many years.—*Johnson's Animal Chemistry.*

CATTLE SHOWS, &c.

BROOKLYN, (Con.) October 21.

Windham County Cattle Show.

The Windham county Agricultural Society held its Cattle Show and Fair, in this village, Wednesday the 9th of October inst.—The first exhibition was the ploughing match, which began at 9 o'clock. Nine teams were entered; the quantity allotted to each team, was one eighth of an acre. This being the first exhibition of the kind in the county, excited great interest, and afforded much satisfaction, to both ladies and gentlemen, assembled to witness it. The team of Mr. Chaffee, of Canterbury, performed its work in the short space of twelve and a half minutes; Mr. Gregg's team of Pomfret, in fourteen minutes; the team of Mr. Spencer, of Hampton, being one pair of two years old, and one pair of yearling steers, in eighteen and a half minutes, in a hand-some manner. All the teams showed they were managed in a masterly style, in the performance of their work, and the whole was executed much to the credit of the owners. After the ploughing match, the society assembled in the meeting-house. Prayers by the Rev. Mr. Fowler, of Plainfield, a member of the society. An address was delivered by Elisha B. Perkins, Esq. of Pomfret, much to his credit, and to the satisfaction of the Society. After the exercises at the meeting-house, the society, honoured by delegates from Rhode-Island, and honorary members of the society, proceeded to view the animals and articles offered at the exhibition; and at 2 o'clock, partook of an excellent dinner, provided by Capt. Mather.

Mr. Erasmus Stelbins, received premiums for the best pieces of broadcloth and cassimere.

A very fine team of about 100 oxen, from Woodstock paraded through the street, and did much credit to the enterprising spirit of the farmers of that town.

The annual meeting of the Rockingham, (N. H.) Agricultural Society was holden at Exeter on the 16th and 17th of Oct. By a vote of the Society last year, the custom of meeting in the spring for the choice of Officers, &c. was abolished, and it therefore became necessary to appropriate two days, instead of one, to the business of the Society at its fall meeting. The

recent anniversary being the first under the new arrangement, it was not to be expected that the exercises and exhibitions could be divided between the two days with so much convenience and satisfaction to the public, as can be done hereafter with the aid of experience. These complaints will doubtless be obviated at the next anniversary.

The exercises of the morning were followed by dinner served up for the Society on the lower floor of the Court House, under the direction of Col. Burley, in his usual style of elegance and abundance. The beautiful and appropriate decorations given for the occasion to this spacious room attracted crowds of admiring visitors, and gave an acceptable pledge of the welcome, which the Society will ever find among the citizens of Exeter.

Among the most prominent articles of manufacture were the specimens of Carpeting offered by Mr. Theodore Moses and Miss Martha Gilman, of Exeter, and Mr. Kent, of Chester. The tilling in that of Mr. Moses was wholly of woollen rags; the beauty of the piece attracted much praise. The hearth rag offered by Miss Sophia Smith of Exeter, was much admired, and was highly creditable to her taste and industry. A pair of Morocco Shoes were exhibited by Mr. Lewis Wentworth of Exeter, made from the skin of a sheep, *which was living ten hours and thirteen minutes before their exhibition in the Court House.* They appeared to be well and skilfully manufactured. A beautiful grass indispensable, and a handsome basket, made of musk-melon seeds, were exhibited by a *young lady of Portsmouth*; and a neat silk purse, knit by Mrs. Brown of Kensington, *who has been blind seventy-seven years.* Twenty apples, exhibited by Capt. Nathaniel Paul, of New Market, weighed 21 1-4 pounds; they were natural fruit from one tree, and of good flavor. Two apples were exhibited by that skilful horticulturist, Nathaniel Adams, Esq. of Portsmouth, being the first and second growth of a tree in his garden. The apple of the first growth was of a large size, and that of the second weighed more than six ounces. Some apples, in fine preservation, the growth of 1820, were exhibited by Rev. Isaac Hurd, of Exeter.

Gen. Samuel M. Richardson was chosen President, and Gen. Elias H. Derby, V. President.

The thanks of the Society were unanimously voted to the Hon. Nathaniel Gilman, (who had held the office of President the three last years) for his faithful, assiduous and valuable services. The Rev. Joel Abbot was appointed Orator for the next anniversary, and Nathaniel A. Haven, Jr. Esq. of Portsmouth, was chosen for 1821, who will deliver the Address at the next anniversary, in case of a failure on the part of Mr. Abbot.

The second day was devoted to the exhibition of cattle, the trial of the strength of the working oxen, the auctions, and the reports of the different examining committees. A very interesting report was read before the Society in the morning, by Ichabod Bartlett, Esq. Chairman of the Committee on *butter, cheese, wine and cider.* This report will be published at length.

Among the animals, most worthy of notice, was a fine imported cow, owned and exhibited by Col. Joshua W. Pierce, of Portsmouth, very remarkable for extraordinary size and beauty. Her girth was over seven feet; her weight

probably exceeded fifteen hundred pounds; and all the distinguishing marks of a good cow were seen in full perfection in this beautiful animal. The bull of Gen. Derby, of the Holsten and English breed, and the bull of the Whidden breed owned by Captain Nathaniel Gilman, of Exeter, well entitled their owners to the premiums which they received. The yoke of fat oxen (weighing 2200 lbs. each,) the cow and heifers, of the improved short horned breed, exhibited by Capt. Nathaniel Gilman, the fine bull of Mr. John Thompson, of Stratham, a yoke of uncommonly large two year old bulls, of Seth R. Shackford, Esq. of New Market, the large calf of John Moulton, of Exeter, the bull calf of Mr. Wells, of Hamptonfalls, remarkable for its rapid growth and fine shape, and a yoke of Steers of Henry Butler, Esq. of Nottingham, were very much admired. A team of several yokes of strong and beautiful working oxen, from Kensington, gave interest to the exhibition, and reflected great credit upon that town, distinguished as it has long been for its excellent farmers. The sow and pigs exhibited by Col. Walker, of Exeter; the swine by John Gordon, of Exeter; and the quarter blooded sow of the Cobbet breed, owned by Col. Chadwick; and the boar of the same breed of William Lane, of Exeter, remarkable for the shortness of its legs and snout, and its depth and thickness, were much commended by the committee. Several excellent Colts were exhibited; and the Stud Horse of Jonathan Clark, Esq. of Northwood, was pronounced worthy of premium.

In the *trial of strength*, the yoke of working oxen, (five years old,) drew the load, which weighed upwards of *sixty three hundred*, up Spring street, with apparent ease. They were immediately put upon the drafts facing the load, and managed it well. The yoke of working oxen, owned by Mr. Samuel French, of Nottingham, drew up the same load, and exhibited uncommon strength and good training. The lead was drawn up by the oxen of Samuel Dearborn, and Dearborn Blake, Esq's. of Kensington.

This part of the exhibition was followed by a trial of the *strength of the purse*, on the floor of the Court House. The butter of Bradbury Robinson, of Greenland, which obtained the first premium, was purchased at 47 cents per pound, for that warm and steady friend to the agricultural interest, Capt. Morris of the U. S. Navy; and the lot of Biley L. Thung, of Brentwood, which obtained the second premium, was sold for 42 cents a pound, to James Rundlett, Esq. of Portsmouth.

Abridged from the New Hampshire Patriot.

THE FARMER.

BOSTON:—SATURDAY, NOV. 2, 1822.

ON SAVING AND MAKING THE MOST OF MANURE.

(Continued from page 37.)

In our former observations on this subject, we protested against the uncleanly, unthrifty and unhealthy practice of permitting decaying vegetable or animal substances to waste away on any part of a farmer's lands or tenements, without the application of earth, peat, or some similar matter to absorb the steam, effluvia, or gaseous products of putrefaction. Those products, we observed, though exceedingly noxious, as well as offensive to man and beast, are healthy and

nourishing to plants. The farmer, therefore, who rests the rank vapors which emanate from decaying animal and vegetable matter, and instead of permitting them to pass into, and contaminate the air breathes, treasures up the invisible particles, which they are laden, and applies them to feed useful vegetables, causes the air to be healthy, and his plan to be thrifty by the same means. "If we consider the subject of manure, we shall perceive one of the most striking beauties and benefits of divine ordination, and of that wisdom, with which we are blessed in all the sacred ways, without knowing it. This very substance had it been useless, must have accumulated in heaps intolerably noisome, and perpetually pestilential; but by the blessing of providence, it is every man's interest to remove those otherwise increasing mountains of filth and by decomposition, in various ways, in a great measure concealed from us, it gives increase to our fields and adds to the means of industry, and the reward the husbandman."*

Those who cultivate the ground do not always take the wise and provident part supposed by Lord Erskine in the sentence just quoted. On the contrary, farmers too often suffer manure to accumulate and waste in heaps, generating effluvia "intolerably noisome, a perpetually pestilential," without fear of fever or famine, both of which are courted by such conduct. Not only dung is allowed to waste its richness on the tainted air, but straw, and other litter is suffered to grow mouldy and consume by what is sometimes called dry-rot, (both of which might be prevented, or the bad effects obviated, by covering or mixing them with a suitable quantity of earth) but dead animals, the contents of privies, the emptyings of sinks, spoiled provisions, the refuse of the dairy, the pantry, and cellar, are allowed to mingle their odors in nauseating and deleterious profusion. Sometimes the highway rendered very delectable in consequence of a dead horse, sheep, dog or cat undergoing the process of composition in a situation most correctly calculated for the accommodation of passengers, and to afford farmer and his family the full fruition of their fragrance. Some farmers hang dead lambs, cats, dogs, &c. in the forks of apple trees or other trees, or throw them on hovels or stumps at some elevation from the ground to give the pestilential emanations a good chance to diffuse themselves, without coming in contact with earth, which might convert them from poison for man and animals into food for vegetables. If, however, such animal remains are deposited in a barn yard or a manure heap, (which seldom happens among good fashioned farmers) they are suffered to lie and on the surface, offending the senses and injuring health perhaps of a whole village. Practices of this kind are reprobated by Sir Humphrey Davy, who says "Horses, dogs, sheep, deer, and other quadrupeds that have died accidentally, or of diseases, after their skins are separated, are often suffered to remain exposed to the air, or immersed in water, till they are destroyed by birds or beasts of prey, or entirely decomposed; in this case most of their organizable matter is lost from the land in which they lie, and a considerable portion of it employed in giving out noxious gases to the atmosphere.

"By covering dead animals with five or six times their bulk of soil, mixed with one part of lime, and suffering them to remain for a few months, their decomposition would impregnate the soil with soluble matters, so as to render it an excellent manure; and

* Extract from a speech of Lord Erskine, delivered one of the annual Sheep-shearings, at Holkham, England.

ing a little fresh quick lime with it, at the time of removal, the disagreeable effluvia will be in a great measure destroyed; and it might be employed in the same way as any other manure to crops."*

If however quick lime cannot readily be obtained to celebrate the conversion of dead animals into manure, is probable (though we do not assert it as fact) that covering the carcasses with a pretty thick coat of unached ashes, and placing over all a quantity of earth or earthy substance, would hasten decomposition, and cure the gases resulting from putrescence. Earth, one, however, will answer a valuable purpose, and time the largest animal will be decomposed, if buried in nothing but common soil; and the latter will serve as a store house, and preserve the products of the former for the use of the crop to which it may be applied.

Not only the carcasses of animals, but their excrements and urine are rendered of little value by long exposure to the air. Indeed every moment of such exposure robs them of some part of their fertility, as well as contaminates the atmosphere. "He who is within the sphere of the scent of a dung-hill, (says the celebrated Arthur Young) smells that which his crop could have eaten if he would have permitted it. Instead of manuring the land he manures the atmosphere; and before his dung-hill is finished he has manured another parish, perhaps another county." As exhalations as possible ought to be suffered to rise from the excrements of animals. Fresh manure should be kept as carefully from the sun and rain as grass which has been cut for hay. When cattle have been stabled over night it would be well to throw their evacuations into small heaps or beds, and cover them at least with a sufficient quantity of earth to prevent fermentation, or absorb its products. This would cost but little labor, and would be so neat and healthy as well as economical, that we are confident farmers will adopt it.

Mr. Young says, "The first object which I have attended to for many years, has been to spread a layer of earth over the surface of the yard; peat is the best for this purpose, with a portion of marle or chalk; in the want of this turf, rich mould, the scourings of ditches and some marle or chalk; but not so much of either as to form so solid a bed as to prevent the penetration of the fluids, which should enter sufficiently to give a dark color to the whole. There is no necessity for removing this every time the dung is removed. As there are no advantages from fermentation in the mass left carried on to the land, no attention should be paid to prevent treading and pressing it. But as it is beneficial to have the whole as equal as possible, it is very useful that the stable dung should be spread over the surface, and not left to accumulate at the door. The same observation is applicable to the riddance of the stable bullock stalls and the hog sties."

It is the fashion among our farmers, and was formerly in vogue in Great Britain, to turn over and mix barn and manure several times before it was carried to the field. This practice however is exploded among the best informed cultivators. Mr. A. Young says, "No turning, or mixing, or stirring; but if circumstances of the richness, or quantity, or weather, have occasioned too much fermentation, or this is suspected, scatter very now and then a quantity of the same earth over the surface with which the yard was bedded, but not in layers. This may be so proportioned as to keep the mass from too much fermentation."

The author of "Letters of Agricola," says, "Earth is a powerful absorber of all the gases which arise from

putrefaction. The earth possesses the property not only of retaining the putrid steams which are formed from the dung of decomposing bodies within itself, but also of attracting the effluvia when floating in the air. The salubrity of the country depends on this latter quality; as the practice of burying the dung under the furrow is founded on the former. The stench proceeding from the dissolution of organized matter never rises through the ground to assail the nostrils, although it is sufficiently offensive from bodies, corrupting in air or water. A strongly dunged field, after being ploughed, sown and harrowed, sends forth a healthful and refreshing smell—a proof that all the putrid vapors, which otherwise would annoy us, are absorbed and retained for the nutrition of the crop. It is on this account that the poorest earth can be enriched in a very high degree by mere exposure to the gases of putrefaction. Put a layer of common soil along the top of a fermenting dung-hill from 12 to 13 inches thick, and allow it to remain there while the process is carrying on with activity; and afterwards separate it carefully from the heap, and it will have been impregnated with the most fertilizing virtues. The composts, which of late have attracted so universal attention, and occupied so large a space in all agricultural publications, originated in the discovery of this absorbing power of the earth, and in the application of it to the most beneficial of purposes. A skillful agriculturist would no more think of allowing a violent fermentation to be going on in his dung-hill unmixed with earth or other matter, to fix and secure the gaseous elements, than the distiller would suffer his apparatus to be set at work without surmounting his still with the worm to cool and condense the rarefied spirit, which ascends in evaporation. In both, the most precious matter is that which assumes the aeriform state; and to behold it escaping with unconcerned indifference, is a demonstration of the most profound ignorance."

(TO BE CONTINUED.)

The *Hampshire, Franklin and Hampden Agricultural Society* held their annual Cattle Show, &c. at North Hampton, on Wednesday and Thursday of last week. The exhibitions (says the *Gazette*) were more interesting than on any preceding anniversary, and attracted a greater concourse of people. An appropriate and excellent Address was delivered by Mr. MILLS, of Southwick. A more particular account of this exhibition will be given next week.

Grand Agricultural Speculation.—It is stated as a fact in the *Poughkeepsie Journal*, that A. S. Pell, Esq. of Hyde Park, N. Y. has growing on his farm upwards of sixty thousand Apple trees, nearly fit to set out. He intends to transplant the trees on about seven hundred acres of rich land in Ulster county, and to raise the fruit, which is chiefly of the kind called the Newton Pippin, for exportation.

At the Brighton (Mass.) exhibition, a Straw Hat was shown, manufactured in Vermont, and thought to be finer than any ever imported. It was sold for eighty dollars. The fair manufacturer was more fortunate than a Miss Nancy Bradley, of Ballstown, (N. Y.) who exhibited at the Saratoga Fair, a Straw Hat, on which she had spent three months. The Saratoga bonnet was equal in quality to No. 53 of Leghorn hats, which sell from \$60 to \$70; but Miss B. only received 13 dollars in premiums from the Agricultural Societies, and 25 dollars from the purchase of her bonnet.—*Phil. Union.*

The National Intelligencer intimates that a piratical establishment has lately been founded in Porto Rico, and states that among the persons embarked in it are several respectable American citizens, and youths of good family, who are thus setting not only the laws of their own country, but the law of nations at defiance. "We have some curious particulars," says the Intelligencer, "of this expedition, which for the present we reserve."

We have nothing new respecting the Greeks and Turks, which can be depended on. There is reason to believe that the former are gaining ground, and to hope that they will at length be emancipated from Turkish thralldom.

It is said that the Congress of Sovereigns will not interfere in the affairs of Spain. The calling together of an Extraordinary Cortes in Spain has been decided on. General Elio has been condemned to death and executed for having formed a conspiracy against the constitutional government.

In France, several editors of newspapers have been convicted of giving false and seditious narratives of the trials of conspirators at Rochelle. Some have been punished by fine and imprisonment.

Health of New York.—On Saturday last, the Board of Health in New York published a note, congratulating their fellow citizens that there was no new case, nor a death of yellow fever to be reported on that day. They recommend to their fellow citizens that previous to occupying their houses they be well ventilated, cleansed, white-washed, &c. That quick lime be strewn in the cellars, yards and privies, fires lighted in the apartments, and acid fumigations made use of.

In New Orleans Yellow Fever reigns in frightful malignity. A letter to the Editor of a Baltimore paper dated Sept. 26, states that "of a population liable to take it, not exceeding 700, exclusive of negroes, the daily deaths have averaged 20," and the day before the date of the letter the deaths were 31.

As a proof of the utter desolation which prevailed in the infected district, the N. Y. Statesman mentions that beans have been plucked from vines growing in Liberty-street, and water-melons from two to three inches long, from vines which grew in Greenwich-street! They are the product of seed thrown out by the inhabitants before they were driven thence by pestilence, and which took root in the scanty soil between the paving stones.

Mr. S. Rogers of New-York, has equalled the British Manufacturer in weaving a shirt whole and perfect.

Thanksgiving Day.—This religious festival is to be celebrated in this State, Maine and Vermont, on Thursday the 5th of December next. In New-Hampshire and Connecticut, on Thursday the 28th of November.

It is said there will not be more than 5000 hds. sugar made in Louisiana the present season. 10 or 12000 bales old cotton remained.

BROWN'S PATENT VERTICAL FAMILY SPINNER.

FOR SALE, at the Agricultural Warehouse, in Chambers No. 20, Merchant's Row, (opposite the East end of the Old Market)—a number of

Brown's Patent Family Wool Spinners,

which are found on trial to be one of the most useful domestic implements that have ever been invented for that purpose, being of so simple and easy construction that a girl of the age of 15 can well do the work of six persons in spinning, and so compact in its form as not to require so much space as a common family spinning wheel. The advantage of this machine over and above the common mode of family spinning, is at once tested in a few minutes operation with the machine; it at once discovers its immense saving of labor, its accuracy in spinning a good thread, and the quantity it will spin. It requires no further examination to judge of its utility than to see it operate. It is afforded at so low a price as to bring it in common use to every practical farmer, and is well calculated for the employment of the inmates of our common town's poor houses.—Any number of Machines can be furnished at the shortest notice, and warranted. Oct. 26.

NATHANIEL DEARBORN...ENGRAVER,
HAS removed to Market Street, No. 33, over Mr. Bailey's Store, West corner building of the stone steps passage way.

Orders for Engraving and Printing Address or Visiting Cards; and engravings on Wood, Brass, or other metals solicited. Door Plates of any style and price, of Brass, Silver or Silver-plated. Nov. 2

* *Agricultural Chemistry.*

BY T. G. FESSENDEN.

"Better is a dinner of herbs where love is, than a stalled ox and hatred therewith."

Love relishes the coarsest fare,
And makes the bitterest morsel sweet,
But hatred taints the viands rare
Of those who exquisitely eat.
If anger, envy, discontent,
Lower o'er your delicate repast,
You'd better in the woods kept hunt,
With nought but nuts to break your fast.
Sooner than sit at meat with pests,
Where smother'd hate torments the mind,
Let hungry Harpies* be your guests,
Like those that with the Trojan's din'd.
On beggars' fragments dine and sup,
Your beverage draw from Sodom's lake.
Or seek from Tantalus' cup,†
Intolerable thirst to slake.
The poorest pot-luck, serv'd with smile,
And eaten with a thankful heart,
Is better than your roasts and broils,
And all French cookery can impart.
Thus Daniel, and his friends of yore,
Who made on pulse their simple feast,
For comeliness were rank'd before
The pauper'd minions of the East.
For love can relish coarsest fare,
And make the bitterest morsel sweet;
But hatred taints the viands rare
Of those who exquisitely eat.

* Harpies were winged monsters of heathen mythology, who invited themselves to a family dinner with the Trojans. Their intrusion is thus described by Virgil:

Tum litore curvo
Extrinusque toros dapibusque epulamur opimis,
At subita horrida lapsa de montibus adsunt
Harpie et magnis quatunt clangoribus alas,
Diripiuntque dapes contactuque omnia fœdant,
Imundo.

Then on the winding shore the tables plac'd,
We sat indulging in the rich repast;
When from the mountains, terrible to view,
On sounding wings the monster-harpies flew,
They taint the banquet with their touch abhor'd,
Or snatch the smoking viands from the board.

PIRTE.

† The Cup of Tantalus is a philosophical contrivance, so denominated from a character in fabulous history, called Tantalus, and said to be king of Phrygia. This personage was condemned by Jupiter to suffer perpetual hunger and thirst amidst a profusion of delicacies, which always receded when attempted to be applied to his lips. To imitate this punishment a cup is made with a syphon fixed inside in such a manner that when nearly filled with any liquid, if one inclines it a little for the purpose of drinking, the syphon draws off the contents; which appear to recede from the lips, as if in mockery of the person attempting to drink from the Cup of Tantalus.

From the Old Colony Memorial.

In Rees' Cyclopaedia, under the article *Cock Chaffer*, is a perfect description of the insect which has committed such unprecedented devastation on the vegetable productions of the earth in a greater or less degree through this county. "*Cock Chaffer*, the *Scarabæus melolontha* of Linnaeus, and *melolontha vulgaris* of Fabricius.* The color is testaceous brown, with the thorax hairy; tail inflected, and a triangular white spot at each incisure of the abdomen.

* When in the beetle state.

"Inhabits the northern parts of Europe, and is highly injurious to agriculture.† The larva is soft and gray, with the head and legs protected by a shelly covering of a yellow brown color. While in the larva state, which continues for the space of three years,‡ it devours the roots, corn, and other vegetables. This mischievous creature subsists also on leaves and tender buds of trees, and is from that circumstance denominated the *tree-beetle*."

"They are eagerly sought after, and devoured by crows, rooks, and other birds, as well as animals; it is the larva of this insect that is so frequently turned up in ploughing, and in quest of which the crows are often seen following the track of the ploughshares."§

In Willich's Domestic Encyclopedia, under the same article (*Cock Chaffer*) is a more detailed and minute description of the insect, agreeing in all the essential points with the preceding; so that to my mind, the insect that has annoyed us so extensively, is identified with the larva of the *Cock Chaffer*; and what remains for us, is, I think, to endeavor to devise the means to destroy the enemy, or so to counteract its ravages, in some degree to render it innocuous.

In the first place, I will suggest the policy of ceasing our hostility to the crow, and the rest of the feathered tribe which subsist on the larva, and grubs of such insects as prey on our fields; and even to extend to them the protection of legislative provision. It is true they are an impudent and mischievous race, and are frequently trespassers on the cultivated fields of the husbandman; but their mischief is limited to a few days after planting, and seldom extends to the ripe corn, as they have at that time other means of subsisting; and should they be driven to resort to our corn fields when nearly ripe for the harvest, is it not far easier to guard against the ravages of an enemy, tangible and that announces his approach by the sound of trumpet, than against the one which is invisible, is preying at the roots of all our hopes, of all our means of subsistence, and in such "innumerable multitudes as no man can number."

The Editor of the Cyclopaedia remarks, "the crow feeds on grain and sometimes trespasses on cultivated fields; but his good services overbalance those little depredations, in the extrication of the maggot of the *Chaffer Beetle*, which feeding at the roots of the corn, would oftentimes destroy whole crops, were they not

† This applies to the early period of its existence; as it increases in size it becomes whiter, and when fully grown is perfectly white, or yellowish white, except its head and legs which retain their primitive color, as also a small spot on each side at each incision of the abdomen.

‡ In the Domestic Encyclopedia the author says—"more than four years"—again, "in the latter end of May they burst from the earth after having lived from four to five years under ground."

§ This applies in England where they are in a degree cherished, and are so tame as to build on the ornamental trees of halls and seats; in this country they are a persecuted race, and are rendered so shy of man that they can rarely be approached so as to be shot.

P. S.—Those of the larva which are half grown or less have disappeared, probably gone deeper into the ground; the full grown remain stationary—just under the sod, are very heavy and inactive—probably about changing to the chrysalis state; and when they emerge from that state I presume they will assume neither the form or costume of the "moth or butterfly," but that of the beetle.

destroyed by these *useful birds*." It is also marked by Mr. Marshal, in his Rural Economy of Norfolk, "that the method of frightening rooks in practice there, is simply to stick up tall bough in the field infested, and to fire a gun near the place; this simple expedient seldom fails of being effectual; they being seldom shot at in Norfolk; where a notion prevails, that rooks are essentially useful to the farmer, picking up worms and grubs, especially the grub of the *Cock Chaffer*, which it is believed, frequently injurious to the meadows. This opinion also prevails in other districts, as they are often seen to follow the plough close, pick up such grubs."

In confirmation of this opinion, I will state the fact, that this season, since the prevalence of this grub, there are now in this town, (at a small distance from the habitation of men) acres that were in the state of sward the last spring, which are now so turned up by the crows and skunks, that they have the appearance as if they had been a pasture for hogs.

The second expedient I will suggest is that of making free use of the plough; although cannot be anticipated as a security, it will not be without its use. The *Cock Chaffer*, guided by instinct, avoids the ploughed ground to deposit its eggs, and has recourse to the sward affording greater security for them and more certain subsistence for the larva; in proof of this we observe, that the crops of corn and potatoes on those fields which were in tith the last season, and more especially those which had been two years under cultivation, have received little or no injury, while those that were broken up from the sward are nearly or quite destroyed. I am aware this can be only an expedient to secure a crop, but not a mean of extermination of the insect; it is impracticable plough to the extent of their ravages; but as our fields must be the next season, necessity and prudence will compel the farmer cultivate more than he would have done under other circumstances; therefore any field that is destined for cultivation the ensuing season, it be ploughed this autumn—it will open to the view of the bird of prey many of the grubs that are now the tenants of the soil—it will prevent a new deposit of eggs—and perhaps interrupt the whole economy of their system, and discover their plan of security, as they appear to be a dull and heavy moulded race, incapable of exertion or expedient; and should the plough effect little or nothing as regards the destruction of the insect, the farmer does not lose labor or expense; he will find himself amply rewarded in the amelioration of the soil, and the abridgment of his labor in that season when he is fully occupied.

PLYMOTHEUS.

In passing through the north part of the town, the other day, we observed a chestnut tree, on which there were ripe chestnuts, a tree was in blossom for a second growth. On noticing this fact, an old gentleman in the company stated that he saw fresh strawberries in his meadow a day or two before.

Lake Guardian.

The difficulties formerly existing in crossing the Connecticut, at Saybrook, are now removed by the operation of a safe and commodious Team Boat.

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I. BOSTON, SATURDAY, NOVEMBER 9, 1822.

No. 15.

FACTS AND OBSERVATIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY.

The American Farmer of August 30, 1822, contains a letter from Professor Green, of Nassau Hall, Princeton, N. J. on the insect, commonly called the Hessian Fly, and a fly called Ceraphron, which sometimes destroys the Hessian Fly, in which are the following remarks:

"I fear the amateurs of Natural History will be able to assist but little in the extermination of so formidable an enemy to our wheat crops, as the Hessian Fly. If the devastations made by this insect are ever arrested, it will in all probability be done by the practical farmer."

"There is a curious fact connected with this subject, not generally known to farmers, and which has led to some little mistakes. There is a fly, called the *Ceraphron*, by naturalists, which is often seen in swarms among the wheat about the same time the depredations are made by the Hessian Fly. This insect is not quite so large as the other, and may be distinguished from it by the wings, which are four in number; the common fly being furnished with two only. The *Ceraphron*, so far from being injurious to the crops, is a great protection to them; for it deposits its egg within the body of the larva or germ of the Hessian Fly, which it eventually kills for its own support; so that whole crops of wheat which might otherwise have been destroyed are thus saved. After the *Ceraphron* has deposited its eggs, their wings are thrown off, so that it appears like the common ant; and this curious fact has led many to believe that the Hessian Fly is nothing more than a species of that insect."

VIRTUES AND USES OF ELDER.

Extracts from *Pomarium Britannicum*, an Historical and Botanical account of Fruits known in Great Britain—by Henry Phillips.

"Sir J. E. Smith has remarked, that this tree, as it were, a whole magazine of physic to rustic practitioners."

"The bark, leaves, flowers and berries, are used with advantage in medicine. The leaves are said to be purgative and emetic, and are applied externally for the piles and inflammations; an ointment is made also with them as well as the flowers; the latter are used inwardly as a carminative.* Infusions made from the flowers while fresh, are gently laxative and aperient;† when dry they are found to promote the cuticular secretions,‡ and to be particularly serviceable in erysipelatous and eruptive disorders.§ Sydenham directs three handfuls of the inner bark to be boiled in a quart of milk and water, till only one pint remains, of which one half is to be taken at night and the other in the morning; and this repeated every day for those afflicted with the dropsy. Boerhave recom-

mends the expressed juice of the middle bark, given from a drachm to half an ounce, as the best of hydragogues,* when the viscera are sound.

"Elder-flower water, the oil of elder, and elder-syrup are also used as medicines.

"The berries are esteemed cordial, and useful in hysteric disorders; and are often put into gargarisms for sore mouths and throats.

"The fungous excrescences, which are often found growing on the trunk of the elder tree, bearing the resemblance of an ear, black in the inside, and of a whitish color on the outside (called *auricula Judaeorum*) are accounted good for inflammations and swellings of the tonsils, sore throats and quinsies.

"The wine made from elder berries is too well known by families in the country to require any encomiums; it is the only wine the cottager can procure, and, when well made, is a most excellent and wholesome drink, taken warm before going to bed. It causes gentle perspiration, and is a mild opiate; and may be taken safely, and with advantage, by those of costive habits.

"If a rich syrup be made from ripe elder-berries and a few bitter almonds, when added to brandy it has all the flavor of the very best cherry-brandy.

"The white elder berries, when ripe, make wine much resembling rich grape wine.

"The buds and the young tender shoots are greatly admired as a pickle.

"The leaves of the elder tree are often put into the subterraneous paths of moles, to drive those noxious little animals from the garden. If fruit trees, flowering shrubs, corn, or other vegetables, be whipped with the green leaves of the elder branches, insects will not attack them. An infusion of these leaves in water is good to sprinkle over rose buds, and other flowers, subject to blights and the devastations of caterpillars."

FATTENING HOGS.

Steam or boil potatoes with oats or pea meal and while hot pound or mash them fine, and have several tubs or vessels to receive them in. Before they are given to swine let them become thoroughly sour, and they will cause them to fatten much faster, and on a less quantity than when they are fed with food which has not fermented and become acid.

RULES OF HUSBANDRY.

Extracts from an Address to the Essex Agricultural Society, by Andrew Nichols, Esq.

1. Cultivate no more land than can be thoroughly ploughed, well manured at once, and kept free from weeds.

2. Never keep land many years under the same crops.

3. Never lay land into grass, except it be well prepared, and in a very rich condition.

Suppose for example you possess a field of arable land, containing eight acres; how can it

* Medicines which purge watery humors.

† Jews Ears.

* Wind-expelling, and promoting insensible perspiration.

† Opening.

‡ Separation of fluids from the skin.

§ Diseases of the skin.

be most advantageously managed? According to the author who lays down the foregoing rules, plough up annually, in autumn, two acres. Let it be cross ploughed, harrowed, highly manured, planted with corn or potatoes, and well tended the following spring and summer. In the spring next following, plough it twice, and sow it with grain and clover. In this way, by keeping the land in rotation, one year under Indian corn or potatoes, one year under English grain, and two years under clover, it would produce the most abundant crops, and be continually growing better, as the large tap roots of the clover especially would greatly ameliorate and enrich the soil. After going through this routine several times, the land would be in an excellent condition to lay into grass, thus to remain till another portion of land could be treated in the same manner. Keeping in view these principles, every farmer can readily apply them to other crops, which it is therefore unnecessary to mention.

IRRIGATION.

Falls of water have been estimated in England to be worth as much for watering the land, as for mills and factories. It is well known that even the temporary streams formed by the melting snows in the spring, if caused to run a few weeks ever dry, gravelly soils, will render them highly productive of grass the whole season. Yet our brooks and rivulets are suffered not only to run to waste, but even to render barren extensive tracts of land in their vicinity. Wherever there is a fall of water running through land suitable for the purpose, let it be divided, and carried as high on each side as it will run freely; throw the intermediate space into ridges about twenty feet wide; along the top of each let a small stream of water be passed occasionally; give the whole a dressing of ashes, or lime; and it will produce the most abundant crops of grass, without any further expense. Admitting therefore that the expense of preparing land in this manner should amount, in the first instance, to a hundred or even to two hundred dollars an acre, it would still prove cheaper than most mowing land which can be kept productive only by frequent expensive manuring. Such land would contribute the whole of its productions to enrich the other parts of the farm; a consideration of no little importance in estimating its value.—*ibid.*

THE WILLOW.

Advantages may be derived from planting low, rocky or boggy lands, which are generally covered with alders and other useless bushes, with common willows. These trees not only produce wood, (which when dried is better than white pine,) faster than other trees, but greatly meliorate boggy soils, and bring in a better kind of grass, which makes excellent pasturage.—They serve to shelter the cattle, while feeding, from the exhausting effects of a burning sun. They prevent rapid evaporation, and probably attract showers; consequently increase the size of adjacent streams, and thereby fertilize soils far beyond the reach of their shadows. Besides,

whatever grows out of the soil ultimately returns to it again, to afford food for other plants which succeed. Consequently the more any soil can be made to produce, the more that, or some other in the neighborhood, will be enriched. Do any doubt the correctness of these theories? Why has Palestine, or the holy land, which once flowed with milk and honey, and supported by its own produce, on an extent of territory not exceeding that of Massachusetts, seven millions of people, become so barren as scarcely to be able to preserve a few thousand miserable wretches? Why has the river Jordan, once, undoubtedly, a noble stream rolling thro' fertile vallies, been reduced to a small brook, winding its way through a sandy desert? You will perhaps answer, the malediction of the Most High rests upon it. True, but the Almighty effects his purpose through the agency of natural causes. It was overrun by victorious armies, and vegetation was destroyed; exposed to the direct rays of the sun, the soil itself disappeared, the Springs were dried up, and fertilizing showers became less and less frequent. The same process is now going on in our naked pastures, many of which, that a few years since were well clothed with grass now produce little or nothing but moss.—*ibid.*

Farmers generally would make their pursuits more profitable if they were careful to send to market the best articles, in the neatest order. Good butter, good cheese, good fruit, good cider, good pork, beef and mutton, will always sell, even when the market is glutted with inferior kinds of the same articles. The difference of the expense of raising or preparing the best, and the more ordinary kinds of these commodities, is often very trifling. The butter, for example, is often bad, rancid, and almost worthless. Yet such butter costs almost as much, perhaps often more, than it would to have made it of the best quality. Butter should always be made, salted and preserved by rule. Despise not, therefore, directions on this subject found in books; for it is impossible always to make good butter, if it be carelessly worked over, and salted as chance directs. The difficulty of making good butter, and of sending it unimpaired to the market, in the hottest weather, may be easily obviated. For, with very little trouble or expense, ice may be kept in a common cellar the whole season.*

By selecting good, sound apples, and properly managing the liquor during and after fermentation, Cider can be made without addition, possessing a fine flavour, and in strength equal to about one fourth its quantity of proof spirit.

* In the middle or one corner of the cellar may be built a bin. Throw down some boards, and cover the bottom with straw; or, what is better, the spent bark of tanneries, generally known by the name of tan, in sufficient quantity to leave it a foot in thickness, under the necessary pressure. In the month of February or March, go to the most convenient pond of fresh water, and obtain a sufficient quantity of ice, cutting or sawing it up in blocks as large as can be conveniently handled, and pile it up as compactly as possible in the bin, leaving a space of one foot or more all round it; fill this space, and cover the whole with tan or straw, and then, unless the cellar be uncommonly open, will keep the whole summer. Two men, and one pair of oxen, will perform all the labour necessary to lay in such a store of ice in one day. Around this ice let the pans of milk be set, and place the pots of cream and butter upon it. Place two or three pounds of ice in each box when the butter is conveyed to market.

By the addition of about twenty pounds of sugar to a barrel of common cider, as it comes from the press, it will fine itself, keep for years, even on the lees, without souring, and be much improved in strength.—*ibid.*

CATTLE SHOWS, &c.

NORTHAMPTON CATTLE SHOW.

The Hampshire Gazette of the 30th ult. contains the General Report of the Executive Committee of the Hampshire, Franklin and Hampden Agricultural Society, respecting the late Cattle Show. It occupies almost seven columns of the Gazette. We can only give the following abridged sketches of its contents.

The premiums awarded the present year, including those awarded upon Horses at a meeting of the Executive Committee in the town of Greenfield, in the month of May last, but without reference to those offered for the greatest quantity of grain and other articles of produce upon a given extent of land, are one hundred and sixty-six, and amount to seven hundred and thirty-six dollars. The committee on Manufactures was composed of Gen. Jacob Bliss, Col. James Shepherd and Mr. Erastus Clarke. The two former only attended to the discharge of the duties assigned them, the latter gentleman being absent.

The first objects of premium referred to that committee were blue woollen cloths, and woollen cloths other than blue, both required to be 3-4 of a yard in width, and cassimeres. Upon these three descriptions of articles, eleven premiums were offered, and seven only awarded. Thirteen specimens were exhibited, and six excluded from consideration of the committee in consequence of their deficiency in width. Of twelve pieces of undressed flannels likewise only two pieces were of the requisite width, and only two premiums awarded, though five were offered. Those undressed were required to be five quarters, and those dressed 5-8 of a yard. The sub-committee recommend the weaving of flannels for fulling at least five quarters wide, and remark that by weaving our flannels of that width we gain 20 per cent. in the operations of weaving and dressing, and at the same time great advantage in the facility and saving with which it is worked. Of dressed flannels five specimens were presented, and two premiums awarded. The two which were denied the premium were left out of consideration, in consequence of their want of width.

Of the linen sheetings, shirtings and diapers exhibited, the committee speak in terms of high commendation. Upon these three different kinds of articles 19 premiums were offered, and 17 specimens presented. The committee awarded a number of small gratuitous premiums upon specimens of webbing, linen hose, silk hose, travelling trunks, chairs, merino wool hats, and other small articles, such as a screw plate, guage, and a number of hammers, all beautifully wrought. They also awarded a small premium to Mrs. Chloe Strong, a venerable lady, more than 80 years of age, who offered for exhibition eight pieces of linen sheeting, containing 42 yards, all spun and wove by herself.

The committee speak in handsome terms of an invention of Mr. Cotton White, of Hadley, for making handles to corn brooms, by means of a hollow auger—of Teapots from the pottery

of Messrs. Crafts, White, & Co. of Whately—various and rich specimens of Cabinet Work presented by Messrs. Judd & Cook, Beach Loveland, and Pomroy & Barns, and awarded gratuities to their proprietors.

Very nice specimens of Straw Bonnets were exhibited, and one of grass, in imitation of the Leghorn flats was highly spoken of.

The display of Cattle was unusually fine—that of grass fed cattle superior to the exhibition of last year in that department. The cattle were generally of the breed of the country, fine form, and in excellent condition. The whole number exhibited was seventy head, although a number were rejected in consequence of not being exclusively grass fed, the committee state that there were many for which premiums were not awarded, richly entitled to them, had any further premiums been announced. The committee likewise make favorable mention of a "beautiful red heifer," exhibited by Mr. George Bridgman, of Northampton—of the number, beauty, activity and strength of the working cattle, particularly a yoke owned by Mr. Ephraim Arnold, of Belchertown.

The Committee upon Sheep, in announcing the principles upon which they have proceeded, remark that the breed of Merino Sheep valuable chiefly for its wool; not that these animals are inferior to the native sheep for the use of the table, as they may, undoubtedly, be grown to nearly if not an equal size with sheep of that description. But the quality of the wool deteriorates, as the condition of the animal, beyond what is termed good store order, is improved. The committee looked chiefly, therefore, to the quality of the fleece, its fineness, its softness, and its uniformity, and next to its quality, giving to the finer fleece the preference, although the coarser one might have been more abundant—they desire to give in their report prominence to the fact, that sheep bearing wool of fine staple, and short, instead of long staple, are the best. They likewise regret that there was so little competition for the premiums offered for native sheep.

The Ploughing Match was attended by great concourse of people. Eight ploughs were entered, and four oxen and fifty minutes allowed to each plough for the performance of the work; the land to be ploughed was one-fourth of an acre. The committee report that the ploughing by the various competitors was unusually good.

The Committee close their Report with the following important remarks:

"By the law of 1819, each incorporated Agricultural Society, within the state, which raise by the subscription of individuals a capital stock of one thousand dollars is entitled to receive in the month of October annually, from the public treasury, the sum of two hundred dollars, and proportionate sum, also, for any further addition by subscription, to its capital stock; provided however, that no society shall be entitled to receive, during any one year, any greater sum than six hundred dollars. Upon an inspection of the Treasurer's books, it appears that the capital stock of this society amounts to three thousand nine hundred and seventy five dollars entitling us, of course, to receive yearly \$600 from the state treasury, and giving us, with \$175 payable annually by 86 annual subscribers an income of \$1010 50. The statute containing the

bove provision was passed in February 1819, and being limited to the term of *five years*, will expire, if not renewed, in February, 1824. The question will soon arise, therefore, as to the propriety of re-enacting or continuing in force the provisions of the act referred to; and it is not unlikely, before that period arrives, that the public sentiment upon this subject will have been distinctly ascertained and expressed.

"It is sometimes remarked, by casual observers, that our cattle shows, with all their imposing pageantry, are calculated merely for the amusement of the public, and do not, in any considerable degree advance the interests even of that class of our citizens, for whose immediate benefit they were first established, the agriculturists.

"However little there may be, either of truth or justice in the suggestions we have mentioned, it is, nevertheless, to be remarked, that the objection, even if correct, would impeach, not the wisdom of the legislature, to whose bounty it is owing that we are able to distribute so large a sum in premiums, nor the public spirit or distinguished liberality of those citizens, to whom we are indebted for the means of becoming the objects of that bounty, but only the discretion or sound policy of the officers, or those who are entrusted with the control of the affairs of the societies themselves.

"The great mass of the people of Massachusetts are either husbandmen, practical agriculturists, or artisans and mechanics, either partially engaged in agricultural labors or immediately dependent upon the cultivators of the soil for encouragement in their different occupations and the means of subsistence. Upon the sea board, it is true, we find multitudes, who having their arms upon the ocean, either in their own persons or through the instrumentality of others, rather from its furrows the sources of wealth. As it respects however, the great body of the population of New-England, four-fifths probably of her citizens are mechanics and farmers. And is it possible that societies like ours, instituted expressly for their encouragement, with an income throughout the commonwealth of many thousands of dollars, can do nothing for the great interests of manufactures or agriculture? And when too the perpetually varying wants of man, real or imaginary, are incessantly calling for improvements in the one, and the earth, with its stores of wealth, is for ever inviting new efforts for their development through the agency of the other?

"Agricultural Societies, as it respects this state, may be considered, for the most part, as of very recent origin. Their growth, it is true, has been rapid beyond example, and if they are as yet destitute, in some degree, of the healthy action and athletic vigor of mature life, they are rather to be fostered as children of high promise, than reproached for not possessing in youth all the characteristics of manhood. Perhaps at some future period, experience may dictate improvements in the distribution of our funds. While a portion of them is reserved for the objects now kept in view, a part may be appropriated to the encouragement of the efforts of genius in the invention of new modes of applying advantageously the mechanical powers, or in aid of societies or individuals, who may be engaged, with a prospect of benefit, in the investigation of the nature of soils. Suitable rewards

may be held out for the prosecution of botanical, mineralogical, or geological researches. In process of time, indeed, such may be the character of the society, and such the correspondent progress of intelligence on the part of its officers, and munificent liberality on the part of its members, that the benefits, resulting from the institution may be too obvious to escape the acknowledgment of the most incredulous, and too intimately connected with the best interests of the commonwealth to require a single effort to secure for it the cordial and hearty and permanent co-operation of the public.

"The members of the society will suffer us to remind them, to whose beneficence we are indebted, as well for our beautiful scenery, fruitful soil, and exuberant crops, as for the various institutions, of a civil and religious nature, which have given to New England its high pre-eminence; and as we view with that complacency of feeling, which even the *Christian* patriot may indulge, the inheritance which has been transmitted us, or the store houses and barns our own industry may have filled, let us remember with humble gratitude, Him who was our father's God, and to whose kindness it is owing, not only that *our pastures are clothed with flocks, and our vallies also covered with corn*, but that our institutions are unimpaired, and our prosperity and happiness, as a people, unexampled.

From the Connecticut Courant.

GRANBY, (*Turkey Hills Society*) Oct. 23, 1822.

Agreeably to previous appointment, the Cattle Show and Fair was attended at this place. The working oxen and steers in yokes, were collected on the green near the Meeting-house, at 10 o'clock, A.M. There were present 36 yokes of 5 years old—37 of 4—75 of 3, and 37 of 2 years old; in the whole 175 pairs. They were all in good working order, and generally well matched. After an appropriate Address, delivered by Mr. Alfred Owen, to a numerous auditory in the Meeting-house, the whole of the cattle, by assistance of the marshals, were connected in one line, making a team of a full half mile in length. In this order they moved about three-quarters of a mile on to a beautiful plain lot in Windsor, belonging to Isaac Owen, Esq. where they were formed into a hollow square, exhibiting a parade novel and highly interesting. The Committees of arrangements and inspection, with their Secretary, accompanied by several gentlemen of respectability from neighboring towns, were conveyed to the parade ground, (not in *coaches* with *sires*.) but in two substantial *carts*, fitted up with benches, and drawn by three hundred and seventy oxen and steers, in a style vastly superior to monarchs and their minions.

The committee of inspection, as well as many spectators, viewed with pleasure the great improvement visible in the beauty and quality of the cattle, since the last annual Show, in Oct. 1821. Much praise is due to the owners and drivers of the cattle, for the laudable spirit manifested, and for the good order preserved by them.

Among so many fine animals as were here exhibited, the inspecting committee felt a degree of delicacy in making very great distinctions between several pairs of superior excellence. They were, however, of opinion, that

the most meritorious of those exhibited, might be presented in the following order:

Best pair working oxen, 5 years old, owned by Joab Owen, of Suffield.

24	do.	do.	do.	Col. T. Leavitt,	do.
3d	do.	do.	do.	Henry Owen,	do.
Best	do.	do.	4 do.	J. Comish, Jr.	Windsor.
2d	do.	do.	do.	P. Stevens,	Southwick.
3d	do.	do.	do.	J. Forward,	Granby.
Best	do.	do.	3 do.	Apollo's Gay,	do.
2d	do.	do.	do.	L. Thompson,	Simsbury
3d	do.	do.	do.	B. Griswold,	Windsor.
Best	do.	Steers,	2 do.	Col. S. Clark,	Granby.
2d	do.	do.	do.	L. Sheldon,	Suffield.
3d	do.	do.	do.	R. Barker,	Granby.
Best	do.	do.	1 do.	E. Bates,	do.
2d	do.	do.	do.	John Vicks,	do.
3d	do.	do.	do.	Joel Clark,	do.

Much gratification was afforded upon the occasion, by the attendance of several gentlemen of distinction from different towns in the county.

It is believed that exhibitions of this nature are well calculated to excite a spirit of emulation among agriculturists, and to improve our stock.

It is thought worthy of notice that James Forward, Esq. exhibited a water-melon raised in his garden this season, the weight of which was 47 pounds, when taken from the vine.

Mr. Atkins' method of preserving Iron and Steel from Rust.

Greasy and oily, or resinous substances, have hitherto formed the basis of the different preparations proposed and employed for this purpose; but in the former, when rancidity comes on, an acid is produced, which corrodes the iron; and the latter, when dry, are apt to crack, and thus afford an inlet to moisture. But melted caoutchouc, or India rubber, Mr. Atkins has found to possess peculiar advantages in preserving the surface of iron from being acted upon by the atmosphere, arising from its little susceptibility of chemical change, when exposed to the air; from its treacherly consistence under all ordinary temperatures, from its strong adhesion to the surface of iron or steel; and, at the same time, from the facility with which it is removed by a soft brush charged with warm oil of turpentine. The finger or a soft brush are the most convenient implements for applying the caoutchouc; and, as soon as the article has been covered, it ought to be set up on end, in order that the excess may drain which will take place in a day or two. The temperature for melting caoutchouc is nearly equal to that required for the fusion of lead.—*Monthly Mag.*

New method of Weaving Mats.

This method consists in disposing in a cheap and coarse kind of loom, a double series of plain and colored lines of longitudinal stripes of twine—the stripes being at intervals considerably apart from each other. These threads of twine being opened in the manner of a warp, by means of the treadles and harness of the loom, either Dutch rushes or the leaves of *Typha latifolia* or greater cat-tails, torn into shreds, are to be introduced from time to time, with a wooden needle, having an eye or opening at one end of it to receive the rushes, to form the shoot, and the twine is closed over them by the continued action of the loom. In this manner, a cheap and useful matting is fabricated, the use of which is now become very considerable amongst us, although the invention is of a very recent date.—*English paper.*

MASSACHUSETTS AGRICULTURAL JOURNAL.
FOR JUNE, 1832.

(Continued from p. 35.)

A letter from John Prince, Esq. of Roxbury, to the Committee on Agricultural productions, dated Nov. 1821, states the following facts, viz. That Mr. Prince kept a large stock for the size of his farm, which is small, his house lot only 57 acres, and was therefore induced to raise largely of roots. The quantity, however, is smaller than he had last season from the same quantity of land under cultivation, owing, as Mr. Prince supposed, to its being principally from pasturage, newly broken up. The productions of the fifty-seven acres were 300 hills of summer squashes (on less than half an acre) which yielded largely, and were daily gathered for a long time, and boiled for a large stock of swine, with the thinnings of mangel wurtzel, &c. &c.—657 bushels of mangel wurtzel at the harvesting, besides a large quantity of thinnings, during the season, and also of leaves at harvest given daily to cows, swine, &c. cost seven cents per bushel. Mr. Prince says, "I think a greater quantity of this root can be raised on suitable soils, than of any other vegetable, requiring not more than one third of the labor that *carrots* do. —100 bushels carrots, on same space of ground adjoining the preceding crop; cost 17 2-3 cents per bushel—537 bushels ruta bage; 3-4ths of them were raised on land broken up the same season, and the sods burnt by an Irishman acquainted with the business, and no other manure on the three-fourths; the cost 3 2-3 cents per bushel; were sown the 29th June, too late by a fortnight, but the land could not be got ready sooner—745 bushels of potatoes, besides early ones, used during the season; they were of 13 different sorts, and cultivated by Mr. Prince for the purpose of selecting the most valuable. The best were the *Elam* potatoe from Rhode Island, and are uncommonly fine. The second best from Gen. Derby, of Londonderry, N. H. and supposed to be the Buckman potatoe from Maine, a new sort. The third from Hamburg, imported by T. B. Wales, Esq. are very fine and yield well. There were so many sorts, and planted on so many spots, that it was impossible to keep the cost—15 bushels of sweet potatoes of very good quality, and the cost of cultivation not more if so much as others; they yield more from the same number of hills, and do best on light sandy land—37 bushels Russian radish, the produce as large as any vegetable Mr. Prince ever raised: some of them weighing fourteen pounds; they keep well through the winter; cattle are very fond of them, and the thinnings were boiled, among other vegetables, for swine. Gen. Derby, of Londonderry, has this year raised more than one thousand bushels altogether on his cornhills (one each) and he thinks it no injury to the corn; they do not seed the first year, like other radishes, but must be cultivated like turnips—100 bushels turnips of different sorts; some of the yellow Aberdeen, from Mr. Young, of Halifax, thought to be the best of any for the table, and keep well; some red tankard and white Norfolk. All were imported seeds, and not sown till the last of July, and principally on burnt soil. I find, says Mr. Prince, when English turnip seeds are used, they should be sown from two to four weeks earlier than our own old fashioned sorts, as the tops grow very large, and the roots do not begin to swell till

the tops are nearly done growing.—Cabbages, a considerable quantity, but did not head well; the soil too dry for them. Besides a considerable quantity of vegetables from a large garden, not more than two hundred bushels have been, or will be disposed of otherwise, than for the use of the farm. Last winter I kept in pits near one thousand bushels of Ruta Baga and Mangel Wurtzel, which did so well, that this season I have nearly as many. The trench dug about one foot deep, and four feet wide, and long enough to contain one hundred and fifty or two hundred bushels each: they are then piled about 3 1-2 feet like the roof of a house, covered eight or twelve inches with straw or meadow hay, and then with the earth thrown out of the trench and enough added to make it, when the weather becomes quite cold, about a foot thick. Be careful not to cover too thick at first, as the heat of the vegetable is great, when confined in so large a body, and would destroy them."

Mr. John Dwinell gives a statement of the cultivation of a lot for a premium crop of potatoes.

"The lot is situated by Bridge street, so called, in Salem, county of Essex, and owned by Messrs. Waitt and Pierce. It was broken up in 1819; soil black, low and heavy. For about twenty years previous to which, it had been mowing land. The last year potatoes were raised on the lot, nine cart loads of barn manure, about twenty bushels white seed potatoes, and whole labour then employed in production of crop, nineteen and an half days.

The cultivation, &c. the present year has been—1st. Four loads of barn, and five of privy manure, for one yoke of oxen, were put on the lot.

2d. The seed, an equal portion of whites, blues and long reds, making in all about twenty-four and an half bushels.

3d. Two days ploughing and half a day furrowing, with one yoke of oxen, no driver; 17th and 19th of May, three days planting; 11th June, three and an half days weeding; 16th July, 3 days hilling; and from 1st October, ten days digging crop, making in the whole twenty-three days labour.

4th. The amount of crop measured five hundred and eighteen and an half bushels on the acre."

Thomas Shepherd, Esq. of Northampton certifies, in substance, that on the 16th Oct. 1821, he measured an acre of ground, across the end of his cornfield, had the produce threshed on the first day of the Cattle Show, brought it to the Show in the afternoon, and sold it under the inspection of hundreds of people. The corn was perfectly hale and dry, and measured 37 bushels and 21 quarts, all produced from one acre of land sowed in rows about four feet apart. The same gentleman caused an acre of land adjoining the above to be measured off, which was sowed in alternate rows of corn and ruta bage; the corn rows being eight feet apart. The produce was sixty-one bushels and twelve quarts of corn, and one hundred and sixteen bushels of ruta bage. The whole field of nearly twenty acres (except the first acre) was sowed in rows eight feet apart, and the half acre, which yielded 61 bushels and 12 quarts, was not better than a fair average of the field. The ruta bage sowed between the corn rows was al-

most burnt up with the drought. The first acre was entered for the Society's premium of \$30, for the greatest quantity of corn on an acre, and the second acre for the premium of \$30, for the best mode of raising corn. The land was dry and the corn *suffered much* from the drought. The field contains nearly twenty acres, which with four others of about the same size is cultivated under a five years' rotation of crops without manure, except the corn year, when it is spread on profusely. It had lain in grass (with out any manure being put on it) three years when it was ploughed in the fall, and manured in the spring at the rate of nearly fifty loads to the acre, taken fresh and green from the barn yard and pig sty, and all made during the winter (except some heaps of compost not very good) by the cattle, sheep and pigs, from straw and oats mixed with the stable manure; the land was cross-ploughed an inch or two deeper than the fall ploughing; the manure covered up as fast as it was spread about from the carts, the turf harrowed fine with light seed harrows; the land furrowed back to back in ridges four feet apart, the tops of the ridges being two feet higher than the bottom of the ditches. The land was then harrowed across the ridges, which filled up the ditches with fine rich mellow earth a foot deep, well mixed with manure, in which the corn was carelessly strowed along *very thick* sprinkling gypsum on it before covering it up. The corn was sown between the 10th and 26th of May, was hoed three times, beginning the first week and ending the last week in June. Mr. Shepherd concludes this article as follows

"I have tried every plan for several years past, and this is the third year that I have sowed it in rows from six to eight feet apart, with a variety of roots and plants between them. The first year I got 41 1-4 bush. to the acre, 0 rather from half an acre; the second year 51 bushels, and this year 61 bushels 12 quarts. I am my belief that 75 bushels corn and 3 or 40 bushels Ruta Baga (or 2 or 300 bushels potatoes can be raised on an acre of good rich ground cultivated in this way; but the corn must be sowed *very thick* in rows eight feet apart, and the ditch well filled with fine mellow earth, and *plenty of manure*, nor is it an expensive mode of culture considering the great crop to be obtained. The cross ploughing and furrowing is extra work, but this it is, with the aid of the harrow: that makes the great crop, if sowed in wide rows, as my experiment this year proves, having got at the rate of 122 bushels 24 quarts to the acre in this way, and in the narrow rows with more exhaustion of the land, only 37 bushels 24 quarts. With regard to the expence of cultivating a single acre of land, the Trustees will please to consider that I do not cultivate any one acre of land with a view particularly to a premium, and therefore cannot ascertain the expence. I would observe however that the extra expence of cultivating corn in this way beyond what it is in the usual way in hills is inconsiderable. They will also decide which of the two is most meritorious, him who cultivates his whole farm alike both as to labour and manure, or him who devotes all his energies to get a great crop, from a single acre, and robs the residue of his farm for the benefit of a premium."

The succeeding articles in this excellent number of the Massachusetts Agricultural Re-

pository are "An Essay on the advantages of manuring with Green Crops—by S. W. Pomeroy, Esq. first Vice President of the Society," which we have republished. (p. 9,) and an article on "The felling of Trees for Timber," by Hon. Timothy Pickering, which we have also republished. (p. 17.)

☞ We have now transplanted into the *New England Farmer*, either in substance, or at length, every article in the last number of the Massachusetts Agricultural Repository, whose more general diffusion we thought might be useful to that numerous and respectable class whose principal occupation is cultivating the earth. In doing this we may, perhaps, incur the censure of some of our readers, who were previously in possession of the work, which has been the subject of our notices and extracts. But we believe that more than four fifths of our subscribers do not take the Massachusetts Agricultural Repository, and many of them would, probably, never have seen much of the useful matter first published in that valuable work, had it not been presented to them through the medium of our paper. We are moreover confident that the liberal use which we have made of the Repository will be so far from giving offence to its conductors, that they will approve of our proceeding, as comporting with their own patriotic views and intentions. Dr. A. Hunter, the author and compiler of several volumes of valuable Essays on Agriculture, invited Editors of Newspapers to make extracts or republish whole articles from his essays, in order that the public might be the more extensively benefited by his labors. Utility rather than originality is our object, and we prefer copying a valuable article from another publication, to publishing original matter, written expressly for the *New England Farmer*, which may have less merit than the article thus copied. We mean, however, always to give credit, to the sources or authors from whom we derive our second-hand articles; and if some editors of newspapers (for whom we hope this hint will suffice.) would deal as fairly by us, they would confer an obligation. If certain jackdaws will not be contented with their own feathers, we will not promise not to divest them of their stolen plumage. We shall handle them with as little ceremony as a hawk would a robin.

To the Editor of the *Utica Gazette*.

SIR—A friend has furnished me with the following account of a very extraordinary crop of corn raised on three acres of land, by Messieurs J. and M. Pratt, of Easton, Madison county, for which they received a premium from the Agricultural Society. The character of these gentlemen, as well as the exertions of a respectable committee to ascertain the truth, preclude all doubt of the correctness of the statement. The effect is unexampled in this county, and I hope it will not fail of convincing many of our farmers that they have mistaken the true source of agricultural profit, and that it may excite in them

a laudable spirit of emulation. If, under a better course of husbandry, we could raise from 50 acres as much produce as we now do, under the present system, from 150 acres, lands would become more valuable and the benefit generally would be incalculable. I understand Messrs. Pratts feel confident, from the result of this experiment, that they can, in a good season, raise 200 bushels to the acre, and that they hope to do it next year.

From the Farmer's Weekly Messenger.

It appears by experiments made in Pennsylvania, that potatoes and corn given in a raw state are inferior to the same quantity when ground, boiled and steamed, forty-five per cent. i. e. if a hog weighs three hundred, and it cost half to fat him with ground corn, and he is sold for four cents, in the one case it will cost six dollars to fat him, and in the other case it will cost eight dollars and seventy cents. If he that sells his pork, when fatted on the best terms, only lives by it, the man who feeds on whole grain must shortly expect the officer after him. It is believed that there is more difference than even the above.

A discovery has been recently made, which promises the most important consequences in a commercial and agricultural point of view.—About two years ago, 200 acres of land, near Flint, in Wales, were planted with the common holyhock or rose mallow, with the view of converting it into hemp or flax. We have been informed, that, in the process of manufacture, it was discovered that this plant yields a beautiful blue dye, equal in beauty and permanence to the best indigo. We relate the circumstance precisely as we have heard it from the most respectable quarter, without pledging ourselves to the fact.—*Liverpool Kaleidoscope*.

From the American Centinel.

TO MY BROTHER FARMERS.

I am sorry that there is so much need of the admonitions I am about to give. Depend on it you do not "work it right," or you would make your farms and stocks twice as profitable as they now are. Many of you farm too much. You would find it much more profitable to farm twenty acres well than forty by halves. The last season, I made ground produce at the rate of one hundred bushels of Indian corn to the acre. Is not this much better than a common crop of 30 or 40 bushels? You will most certainly say it is, and with the same breath ask how I managed to make it produce so plentifully? My ground being much infested with ground mice, or moles, and also overrun with grubs and other vermin, I put on, early in the month of March, about seven bushels of salt to the acre, which thoroughly destroys all kinds of vermin, being an excellent manure; early in April, I gave it a good coat of stable manure, and ploughed and worked the ground over and over, until it became completely mellow; I then had every corn hole filled with hog manure, and after dropping my corn, which had been previously soaked in warm water, I scattered a pint of lime over every hill, and then covered the whole with a little mellow earth. In about one week the corn began to come up plentifully, after which I nursed it well with the plough and hoe every other week for eight weeks, at which time it was as high as my head, and not a spire of it was destroyed either by the frost, grub or birds. My other things I nursed equally as well, and I have been amply paid for all my extra care and trouble, as I raised more than twice as much per acre as any of my neighbors, and did it in much less time—I mean I got all my harvesting done two or three weeks before many others. This is accomplished in a great measure by redeeming time; rising between 3 and 4 o'clock in the morning; then if the day be very sultry and hot, I lie by from 12 to 3, and then I feel refreshed and able to go to work until quite dark—this I call "working it right." Whereas, should I lay in bed until the sun be up and shame me, haunt the taverns at night, drink too much whiskey, but half manure, half plough, half plant, half nurse, half harvest, and do every thing else by halves, I surely should not "work it right," nor get half a crop.

I shall now conclude, by giving you, for further consideration, a few excellent observations from a wiser head, perhaps, than my own, which I shall endeavour to improve for myself, and hope every brother farmer will do so likewise, viz:—

I often say to myself, what a pity it is our farmers do not work it right. When I see a man turn his cattle into the road to run at large, and waste their dung, on a winter's day, I say this man does not work it right. Ten loads of good manure, at least, is lost in a season, by this slovenly practice—and all for what? For nothing indeed but to ruin his farm.

So, when I see cattle late in the fall, or early in the spring, in a meadow or mowing field, poaching the soil, and breaking the grass roots, I say to myself, this man does not work it right.

So when I see a barn yard, with a drain to it, I say the owner does not work it right, for how easy is it to make a yard hollow, or lowest

in the middle, to receive the urine and all the wash of the sides, which will be thus kept dry for the cattle.

The wash and urine of the yard, mixed with any kind of earth, or putrid straw, is excellent manure; yet how much do our farmers lose by neglecting these things:—in fact, *they do not work it right.*

When I see a farmer, often going to the retailer's store, with a bottle or jug, lounging about a tavern, or wrangling about politics, or quarrelling with and defaming his neighbour's good name, I am certain such a man *does not work it right.*

A PENNSYLVANIA FARMER.

From the London Globe.

MOST IMPORTANT DISCOVERY.

Six weeks since, application was made to a person for the loan of *one hundred pounds* to a young chemist, who had a discovery he was too poor to substantiate by experiment. The money was obtained, and in a few days repaid by the borrower, already raised to sudden affluence by the private disposal of his invention:—It is a new mode of tanning skins, combining such rapidity and economy, as promise to the publick an immediate and immense advantage. Raw hides, hitherto lying twelve months in the tan pit, and subjected to a process otherwise defective and precarious, are now perfect leather within six weeks, and at less than half the expense. The gentleman who bought the invention, is a noted opposition member and contractor; and from the terms of his stipulation, we may form some judgment of the probable magnitude of the results. He has paid him 10 000*l.* down, he has given obligatory deeds, securing him 5000*l.* on the 1st. of January, 5000*l.* per annum for the four years next succeeding and afterwards 11,000*l.* a year for life! It is expected the price of a pair of boots will not exceed eight shillings, and a corresponding fall will be produced in all articles of leather manufacture.

From the Philadelphia Union.

GAS FROM OIL.

A company at Boston has established works for making gas, and obtained permission from the city authorities to lay iron pipes from three to four inches in diameter, in the streets, for the purpose of supplying such parts of the town as will receive a sufficient quantity of gas to indemnify the company for the expense.

The gas proposed to be used, is that obtained from oil, which, it has recently been discovered, is far preferable to that obtained from coal.—The apparatus, Professor Silliman states, is much less expensive—occupies much less space—requires less skill and labour to manage it, than the coal gas apparatus—is not so liable to wear and tear—and as there are no offensive products to be removed, it may, on its present approved construction, be introduced into any dwelling-house. All the costly and offensive operation of purifying the gas by lime, &c. is totally avoided when it is obtained from oil.

The material from it is produced, containing no sulphur or other material, by which it can be contaminated, there is no objection, on account of a suffocating smell, to the use of oil gas in close rooms; and, as it contains no unmixed hydrogen (which occasions the great heat of the

coal gas,) there is no greater proportionate heat from the flame, than from that of lamps or candles. It does no injury to furniture, books, plate, pictures, &c. and contains nothing which can possibly injure the metal of which the conveyance pipes are made.

AMERICAN MANUFACTURES.

Messrs. Adams, Allen & Co. have lately established in the vicinity of Pittsburgh, a manufactory of cotton yarn and piece goods—the first of the kind which has been established in Pennsylvania, west of the mountains. They have already put into operation upwards of 500 spindles and eight power looms, and are now engaged in constructing 1000 additional spindles, which will be put in operation in the ensuing spring.—These spindles will supply yarn for looms sufficient to weave from 1500 to 2000 yards of piece goods per day. At present, there are about 20 hands employed, principally females. The whole machinery, which is of the latest and most approved kind, will be driven by a steam engine of about thirty-five horse power.—*ibid.*

SQUIRRELS IN OHIO.

A letter from the Ohio country, an extract from which is published in the Woodstock, Vt. Observer, states that whole fields of corn from 6 to 10 acres, are wholly destroyed by grey and black squirrels—not an ear left. During a squirrel hunt of about a week in the neighboring towns about Columbus, the first part of Oct. nearly 20,000 were killed. Hundreds were seen every day swimming the Great Miami, Mad River, Scioto, and other streams. Children from 6 to 10 years of age, would wade into the shallow water, before the squirrels reached the shore, and kill them with sticks. Many of them are fat and fine eating. We saw many little boys and some men, with from ten to thirty or forty on their backs. They seem to be almost as destructive as the locusts formerly were in Egypt. It is supposed that they are in pursuit of nuts, and attack corn-fields. Notwithstanding the depredations of these animals, corn and oats in many parts of that country are only 12 1-2 cents per bushel; wheat, by the quantity, from 25 to 37 1-2 cents per bushel; butter and cheese from 6 to 10 cents per pound.

The season has been very good in some parts of the Ohio country, but in some parts of Pennsylvania, Virginia and Maryland, almost every thing is destroyed by drought.

Longevity of the Clergy in the Old County of Hampshire.—The following passage of a letter from the Rev. Enoch Hale, of Westhampton, is inserted in the last North American Review:

"When I was ordained (in 1779) there were, including myself, 34 or 35 ministers in Hampshire county. Of these nine are now living, and I am the youngest of the nine. Two are above 75, and have colleagues. Four perform the ordinary ministerial duties, two of them are above 70. One was dismissed and is about my age. In 40 years, only one minister has died, within the present limits of Hampshire county, under the age of 70. Of those who have died within the limits of the old county, (as it was in 1779,) one was nearly 100, three about 90, one 83, eight about 80, and eight about 70."—*Hamp. Gazette.*

THE FARMER.

BOSTON:—SATURDAY, NOV. 9, 1832.

On the Metamorphoses and Manners of the Cock-chaffer Fly, the Scarabeus Melolontha, Lin.; with Hints tending to lead towards some means of destroying it

PLATE I.

PLATE II.

Plate I. is a representation of a full grown insect. The small dots at the end of each of the vertebrae or joints, are shining specks which are the air holes thro' which it breathes.

No. II. represents the same insect after it has changed to a fly or miller.

The eggs of this insect are deposited by the mother in the ground, from each of which proceeds, after a short time, a small whitish worm with six feet, that is destined to live in the earth under that form for the space of four years, and there undergo all its changes, until it finally assumes its pupa form [form of a winged insect] subsisting, during its abode in the earth, upon the roots of trees and other plants that grow in the soil, committing ravages among these crops, on some occasions, of the most deplorable kind. After it assumes its winged state, it devours the leaves of trees and other plants with an avidity not much less than that of the locust; so that in certain seasons, and in particular districts, they become an oppressive scourge that produces much misery among the people. Fortunately their ravages are but temporary and local, being moderated by circumstances in nature with which we are yet in a great measure unacquainted.

As soon as the worm issues from the egg, it seizes upon such roots as it finds nearest to it, and devours them, living all the summer under the thin coat of vegetable mould, near the surface; but, as winter approaches, it descends deeper into the earth, and, penetrating directly downwards, retires beyond the reach of the frost, where it remains in an inactive state, and without food, till the return of spring, when the warmth of the season invites it to ascend and begin its ravages anew upon the roots that spread themselves through the tender mould near the surface. In this manner it proceeds for three or five successive seasons, changing its skin at least once a year. It is not till the end of the fourth year that the larvae are metamorphosed; for then, towards the end of autumn, they go deep into the earth, sometimes six feet, and then spin themselves a smooth case, in which, after quitting their last skin they change into the pupa, or chrysalis. The pupa remains under this form all winter, till the month of February, when it comes out a perfect Scarabeus, soft and white. It is not till the month of May, however that the parts become hardened, and they come out of the earth in the day time; and thus we often find it

the earth perfect cock-chaffer flies; which has made many persons think that these insects live from one year to another, and pass the winter in the earth to protect them from the cold.

These worms, though they are always white, yet are sometimes found varying, more or less, wholly, or in part, into a bluish tint, produced by the internal parts, seen through the transparent skin.

These scarabei are seen during the whole summer, especially towards the end of May, and in June, flying in the evening towards sun-set, particularly where there are trees. They seem to be a heedless kind of animal, that fly briskly without regarding much where they go, and therefore become extremely troublesome to persons who walk in places that they frequent, by their darting frequently, and with force, upon the face and other parts of the body, which, when naked, prove very teasing. They eat the leaves of most species of forest trees, as well as fruit trees.

In the United Provinces of the Low Countries, the children amuse themselves by attaching a long thread to one of the hinder feet, and leave them thus to fly without suffering them to escape; they fly then commonly round, describing a circle in the air; from which some think they have obtained the name of *molinears*, that is to say, millers; the probability is, however, that they have obtained that name from the greyish hairs, resembling powder on a slight look, or the whitish dust with which their bodies are covered.

The Society of Arts in London has for many years past held forth a premium for the best account of this insect, and the means of checking its ravages, but without having produced one successful claimant.

In order to destroy these insects, some English writers recommend to cherish and protect rooks, magpies and jays, whose sole employment, for some months, is to search for insects of this sort for food.—“A cautious observer, says Dr. Anderson, having found a nest of five young jays, remarked, that each of these birds, while yet very young, consumed fifteen at least of these full-sized grubs in a day, and of course would require many more of a small size; say that on an average of sizes, they consumed twenty a piece; this for the five makes one hundred. Each of the parents consumes, say fifty; so that this pair and family consume two hundred every day. This in three months amounts to twenty thousand in one season; but as the grub continues in that state four seasons, this single pair, with their own family alone, without reckoning their descendants, after the first year, would destroy eighty thousand grubs. Let us suppose that the half, viz. forty thousand, are females, and as it is known that they usually lay about two hundred eggs each, it will appear that no less than eight millions have been destroyed, or prevented from being hatched by the labors of this single family of jays.

These insects afford a most acceptable food to ducks, turkeys, and the other inhabitants of the poultry yard, which are remarked to lay a greater number of eggs when thus fed, than at any other time. Swine likewise devour them greedily, if they be first bruised and mixed with their other food.

The ravages of the grub are sometimes not experienced for many years together. At other times they appear in immense numbers, without our being able to assign any reason for it. This is thought to be owing to the long period that this insect lives in its grub state, during all which time it cannot multiply, and must be subject to a variety of accidents that may destroy it, without ever allowing it to come within the reach of our cognizance.

Cabbages, cauliflowers, and strawberries, are all much relished by the grub, but lettuce seems to be its

most favorite food. In lands infested with the grub, gardeners sometimes make use of this as a bait to destroy them. They plant a row of lettuce plants between the rows of strawberries. In that case the grub attacks the lettuce. The gardener, aware of this, examines his plants with care each day, going along the rows with a trowel in his hand, and wherever he sees the leaves falling, he knows that the enemy is there, and immediately digs up, and destroys the grub.

It is thought that the whole race of grubs are sometimes destroyed by winter rains; and wherever irrigation takes place, the destruction of the grub must be effected. If a stream of water could be spread over the surface of a grass field only for a few days, during any of the winter or spring months, it is supposed that the grubs might thus be drowned in their holes. Dr. Anderson recommends this mode of destroying grubs, in grass lands which are infested with them, especially when it is intended to turn them up to corn, (wheat, rye, &c.) for the mischief grubs do in these circumstances to the first corn crop is often very great. It might, says Dr. Anderson, even with safety be applied to orchards and wood-lands; for these would sustain no damage were not the water continued longer than is necessary for the destruction of the worm.*

Dr. Darwin says in *Phytologia*, sec. xiv. 3, in speaking of the *Scarabæus Solstitialis*, or fern chaffer, “when the fly is seen to come out in abundance in the summer evenings on grass lands and fallows, it is probable that rolling the ground in the evening might prevent the return into the earth, both of these and of the may-chaffers, to deposit their eggs and thus prevent their future progeny; or during their grub state, when they exist at the roots of wheat above, or just beneath the surface of the soil, perhaps slacked lime might be sprinkled over the crop in powder, or sea-salt in powder, which might be washed down the stems of corn in a wet day, and destroy the insect, without injuring the vegetable; or lastly tar water; all which might be first tried on a small part of the field; for as lime is not all of equal purity, it is not all of equal strength or causticity.” The same author, in speaking of the white slug in gardens, says, “It has lately been asserted, that watering the ground with tar water will destroy them, which may be made by adding a few pounds of tar to a hog-head of water, and well stirring it, without perceptible injury to the tar.” *Phytologia*, sec. xiv. 3, 5.

There is no doubt but common turpentine might answer as good a purpose as tar, if made use of in the same way. Infusions of elder are likewise, it is believed, fatal to all sorts of insects. Lime water would be a cheap application, and a quart of quick lime would more than saturate a hog-head of water, for lime cannot be taken up or held in solution in less than about 700 times its weight of water. Any of these liquid substances may be applied to a soil infested with worms, either by a common gardener's watering pot, or by letting the liquid out of a barrel or hog-head, by a pipe communicating with a tube 10 or 12 feet in length, with its ends closed, and bored full of small holes five or six inches apart, and placed either before or behind the wheels of a cart, across, or fastened under the body, in such a manner that the liquid may issue through holes and wet the ground equally, as the cart is drawn over it. Or in other words, wet your grounds with lime water, &c. when the grubs are near the surface, by an apparatus similar to that which is used for wetting the streets of cities in hot and dry weather. If such applications should not kill the worms

* This account is principally abridged from a paper in the 3d volume of *Anderson's Recreations*.

it would probably spoil their appetites, and lime water would, moreover, in many instances, be useful as a manure.

LATEST FROM EUROPE.

An arrival at New York brings intelligence from London to the 22d and Liverpool to the 24th of Sept. The Greeks are proceeding with rapid and victorious strides to the achievement of complete independence. They attacked the Turks before Argos on the 23d July, and defeated them, after a furious contest. On the 24th and 25th the Turks were harassed on their retreat by the Grecian sharpshooters. An obstinate battle at length took place, near Corinth, in which more than 1500 Turks perished. On the 6th and 7th of August, likewise, the Turks were defeated with great carnage, 3000 remaining dead on the spot. The number of wounded and prisoners is not known, but two thousand Turkish horses, all their baggage and munitions, together with their military chest were among the fruits of the conquest. Up to the 13th of August, the date of the last accounts, the Greeks were triumphant, and news was every moment expected of the complete destruction of the Turkish army.

In Spain the Constitutional party are successful, and their enemies are submitting or retiring from the scene of action.

The Congress of Sovereigns were assembling at Verona, at the date of the last accounts. Nothing favorable to Greece, it is said, is expected to result from the deliberations of this body.

On Monday last, the election of Representatives to the next Congress, took place in this State. In *Suffolk* District, Mr. Webster is elected—in *Essex*, North, Mr. Nelson—in *Middlesex*, Mr. Fuller—in *Norfolk*, Dr. Estis—in *Bristol*, Mr. Baylies—in *Plymouth*, Mr. Hobart.—In *Hampshire S.* Mr. Lathrop is probably elected, and Mr. Allen in *Hampshire N.* It is supposed no choice has been made in *Essex S.* and *Worcester N. and S.* Districts. The other Districts in the State not heard from.

Rapid Growth.—The following singular instance of the rapid growth of an engrafted scion, is worthy of notice, and will be interesting to virtuosos.

A Mr. Foster, of Scituate, grafted in his orchard, in May last, an apple tree, which in four months from the time the scion was set, bore an apple which girted 6 3-4 inches in circumference.—*Gazette*.

Mr. Coke, the rich and hospitable English Commoner, has discontinued his Annual Agricultural Festivals, where for so many years he had entertained many hundreds of the most distinguished friends of Agriculture, and Practical Farmers of England and of Europe. In a letter to one of his friends in America, he says, he has been compelled to reduce his rents thirty-three and a third per cent, and his tenants are known to be better able, than any others in England, to support the existing burdens on that class of British population.—*ibid*.

Premium offered.—The Emperor of Germany has lately offered a thousand gold ducats, equal to \$2000, to the author, whether native or foreigner, for the best treatise on the construction of water mills.

A Velocipede, with two wheels, has been constructed in England, by which a person, with considerable ease, may travel six miles an hour.

NATHANIEL DEARBORN...ENGR. & C^o,
HAS removed to Market Street, No. 33, over Mr. Bailey's Store, West corner building of the stone steps passage way.

Orders for Engraving and Printing Address or Visiting Cards; and engravings on Wood, Brass, or other metals solicited. Door Plates of any style and price, of Brass, Silver or Silver-plated. Nov. 2.

UNPRINCIPLED AMBITION.

BY T. G. ESSENDEN.

Ambition improperly directed, and destitute of principle, is a fruitful source of human misery, and causes most of the calamities of life. Many of its votaries, instead of rendering themselves notable become notorious, and obtain infamy in escaping obscurity. They cannot endure the idea of gliding silently down the stream of life into the gulf of oblivion, without leaving so much as a bubble or a ripple behind them; and therefore trouble the waters as much as possible during their passage from time to eternity. It is to be feared that there are more men like Eratostratus, who set fire to the temple of Ephesus for no other purpose than to preserve his name from oblivion, than like the "Man of Ross" who did good without seeking fame, and found that

"One self-approving hour whole years outweighs,
"Of stupid starers, and of loud huzzas."

But the man is happier both here and hereafter, who

"Along the cool sequester'd vale of life,
"Still keeps the noiseless tenor of his way,"

than he who "wades through slaughter to a throne," and "shuts the gates of mercy on mankind."

Dr. Darwin, in his elaborate work entitled *Zoonomia*, treats of Ambition as a disease, and thus describes its symptoms, and method of cure.

"Ambition.—A carelessness about the opinions of others is said by Xenophon to be the source of impudence; certainly a proper regard for what others think of us frequently incites us to virtuous actions, and deters us from vicious ones; and increases our happiness by enlarging the sphere of our sympathy, and by flattering our vanity.

Abstract what others feel, what others think,
All pleasures sicken, and all glories sink.....POPE.

"When this reverie of ambition excites to conquer nations or to enslave them, it has been the source of innumerable wars, and the occasion of great devastation of mankind. Cæsar is reported to have boasted that he had destroyed three millions of his enemies, and one million of his friends.

"The works of Homer are supposed to have done great injury to mankind by inspiring a love of military glory. Alexander was said to sleep with them always on his pillow. How like a mad butcher amid a flock of sheep appears the hero of the Iliad, in the following fine lines of Mr. Pope, which conclude the twentieth book.

His fiery coursers, as the chariot rolls,
Tread down whole ranks, and crush out heroes' souls;
Dash'd from their hoofs while o'er the dead they fly,
Black, bloody drops the smoking chariot dye;
The spiky wheels through heaps of carnage tore;
And thick the groaning axles dropp'd with gore.
High o'er the scene of death Achilles stood,
All grim with dust, all horrible in blood;
Yet still insatiate, still with rage on flame;
Such is the lust of never-dying fame!

"The cure must be taken from moral writers. Woolaston says Cæsar conquered Pompey; that is, a man whose name consisted of the letters C. a. s. a. r. conquered a long time ago,

a man, whose name consisted of the letters P. o. m. p. e. y. and that this is all that remains of either of them. Juvenal also attacks this mode of insanity. Sat. X, 166.

Idemens et savas curre per alpes
Ut peris placeas, et delectatio fias.

Which is thus translated by Dr. Johnson:

And left a name at which the world turn'd pale,
To point a moral, or adorn a tale."

If Dr. Cautic may be permitted to add any ingredients to Dr. Darwin's prescriptions, he will give the following moral

ANTIDOTES TO AMBITION.

When men of arrogance attempt to soar

Above the limits of their destin'd sphere,
Their every effort serves to sink them lower,
Curtain'd and baffled in their mad career.

Yet witless wights, in rash pursuit of fame,
Strive for pre-eminence of power and place;
Who, if they gain the rank at which they aim,
Become the heralds of their own disgrace.

Some fools are smitten with the love of dress,
And spend their little all to make a show;
Pride proves the cause and prelude of distress;
Attempts at high life bring the coxcombs low.

Some splendid sinners, proud of being vile,
For gentle vices high pretensions urge,
Enact the rake and debauchee in style,
And claim a wreath for meriting a scourge.
Some place their pride in wealth, by fraud obtain'd,
Cash, houses, lands, the purchases of guilt;
The conqueror boasts of battles he has gain'd,
And laurels drench'd in blood unjustly spilt.

All such vain-boasters glory in their shame,
The meed of vice no honor can bestow,
Impell'd by pride, bad eminence their aim,
They gain, at last, pre-eminence in woe.

From the Old Colony Memorial.

In the New England Farmer, Oct. 26th. are extracted from President Dwight's tour in New-England, some remarks on the *Beach Grass*, and its utility as manifested by its improvement on Cape Cod. The Editor requests "any friend or correspondent to furnish information relative to the above mentioned grass."

Little can be added to the judicious and critical remarks of the respectable tourist—but it may be remarked, that its production is not peculiar to Cape Cod; it grows spontaneously in all situations similarly constituted. It delights only on the open, exposed beach, and that constituted entirely of white sand, or pure silex, without any adhesive mixture; it is never seen on the adjoining meadows or upland, although within convenient distance to have its seed wafted on them by the wind—and it is believed to be incapable of being produced where there is any soil.

This harbor is defended from the sea by a beach on either hand, of similar formation; that on the north side, which extends from the Gurnett to Marshfield, three or four miles, is called Salt-house beach—that on the south side, and emphatically called the *Plymouth Beach*, extends from Monumet northerly about one mile and an half, and are both, more or less, covered with this grass; and so impressive is the opinion of its utility, that they are protected, and have long been, by special acts of the Legislature, preventing them being fed by the neighbouring cattle.

From the Vermont Republican and Yeoman.

ON WELLS.

As the preservation of health depends much upon the state and quality of the water in use, it is of the utmost consequence that no efforts should be spared to preserve it in its purest state. For this purpose I would strenuously recommend the use of wells and buckets, although water may be obtained with much greater facility by the aid of pumps. As pumps very much lessen the manual labour in procuring water, they certainly answer valuable purposes, except for family uses. It is well known that motion constitutes the life, and conduces essentially to the purification of water. As pumps receive the water near the bottom of the well, by means of holes in the penstock, the water in the well undergoes very little agitation. This stagnant state of the water is soon accompanied with a disagreeable smell and taste; and the water becomes coloured. These changes not unfrequently are very erroneously imputed to the wood of which the pump is made, when, in reality they are all consequences of the stagnation of the water. Water in this state, becomes extremely unwholesome, and insalubrious, and is deprived of its most essential qualities for washing. How often have I lamented the ruin of excellent wells of water by the introduction of pumps! They, however, might be again restored to their former purity and sweetness, by the use of the bucket.—Good water may be designated by its transparency, and its exemption from smell or colour.

Although the motion of the water, produced by the bucket, is calculated to preserve its salubrity, still much care and vigilance are required in guarding against poisonous and nauseous reptiles which so frequently infest wells. Among others perhaps the lizard is as frequently an unwelcome tenant as any. This reptile sometimes grows to a large size, becomes spotted, and is reputed extremely venomous. The best method that I have ever discovered to destroy these troublesome animals, which more or less infest more wells, is the following: Put some vessel into the bucket, containing sulphur, with some combustibles, and after setting fire to these, lower the bucket into the well. If the well be deep, it may be necessary to recruit the fire a number of times, as the moist and dense air will serve to extinguish it. But if you succeed in filling the well with a strong sulphureous smoke, you will drive these animals from their haunts in the walls to the bottom of the well, from whence they may be easily taken when the smoke subsides.

Wells that have ever been good, may again be restored, by often exhausting the water.—The more water is taken from wells, the purer and better the water.

Suppose that a farmer consumes thirty cord of wood yearly.—A green cord of wood is computed to weigh fifty-six hundred weight, and: cord of dry wood thirty-eight hundred weight:—It appears, he that sleds green wood sleds twenty seven tons of water more than the other; and when we come to reflect that it often times happens in our hill towns that they sled the wood half a mile up hill—surely it is time farmers began to think about things that differ, and word head work as well as hand work, if they would thrive.—*ibid*

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I.

BOSTON, SATURDAY, NOVEMBER 16, 1822.

No. 16.

TO THE EDITOR OF THE NEW ENGLAND FARMER.

Sir—Having seen in your papers some observations on the grafting and raising of apple trees, in which I have had much experience, am free to communicate the result of my observations.

I differ in opinion from such European authors as recommend the ground for nurseries to be made extraordinarily rich, as I have observed that young trees, transplanted from a richer to a poorer soil, do not flourish or become so productive as such as are transplanted from a poorer to a richer soil.

The seeds of apples will not produce the same kind of fruit; that I have fully proved, by one experiment. I raised in my garden, from the seeds of one favorite apple, ten trees, that after being transplanted in my orchard, grew to bear fruit. Not one of them resembled their mother apple, and no two were like each other. Seven of them produced very small sour apples, some white, some striped, some yellow, some early, others late. Those seven trees I marked for grafting. Of the other three, the largest and most thrifty tree produced an excellent, pleasant, long, striped apple, of good size, very mellow and juicy in autumn, neither sweet nor sour. The next largest tree produced a red, sweet apple, about the shape and size of the flat pippin, and will keep in the winter near as well. The other, the smallest tree of the ten, which grew the longest time before it produced, bore large, yellow, flat, sweet apples, that weigh about one pound, and fall off in due time for drying or making cider.

I have estimated such parts of my orchard as have been planted with trees, without grafting, to average about three good and valuable kinds of apples, from every ten trees. I disapprove of grafting the trees, when small in the nursery, as we may cut off better fruit than we insert, and perhaps destroy some better and rarer kinds than are yet known.

I believe in *Darwin's* ideas, that the different kinds of apples have their certain age, after which they depreciate and expire, and that grafting is but an elongation of the same declining kind of tree—especially as the *Fandee*, that used to be so large and fine since my remembrance is now extinct, in the place of my nativity, with a bitter rot, and the *flat pippins*, *Rhode Island greenings*, and *blue pearmains*, are very much depreciated in size and flavor.

At an early period of life, I was instructed in the practice of grafting, and thought I understood it perfectly, but a circumstance took place to convince me to the contrary, by some important facts in that art that should be generally known.

Thirty-five years ago, last winter, I was travelling in the upper part of Maryland, near the banks of Potomac river, and was informed that they had a curious old German doctor, a man of great science, that had paid much attention to orcharding;—that he had made between 200 and 300 acres of grafted orchard, and made vast quantities of cider all winter to supply the cities of Baltimore and Alexandria, besides feeding

and fattening a large stock of creatures. I turned out of the road and went to see him, and was surprised, as I rode to the door, to hear him tell his negro, in German, to give my horse half a bushel of sweet apples. His situation was on lime stone land, of a S. W. descent—some very rough—but his trees appeared to grow well amongst the rocks. In places where the ground suited he irrigated it with lime stone springs, for mowing land. His orchards were too extensive for my view. He had a number of large frame buildings, in which he had vast quantities of apples gathered to freeze, and said that apples after being frozen made the most and best cider. It was a mild thawing time, and he had abundance of people making cider. They groomed their soft apples under large wooden wheels, turning in circular troughs. On the beds of the presses they had frames of slats in which they put straw to retain the soft pomace. Their presses were long beams, say 60 feet, raised and drawn down with levers. As the establishment stood on descending ground the cider ran from the presses in troughs, and passed through several strainers before it entered the casks.

He informed me that he had been bred to orcharding in Germany, that he had raised and planted all his trees, and grafted the greater part of them, after they began to bear, if he disliked the fruit.

I observed that I thought the season would be too short for grafting so many trees. He told me that it might be performed any time in the fore part of summer, if a wet growing time, and I would observe the following directions:

1st. Be careful not to loosen the bark of the stock in splitting it; and the safest way to guard against that is to split the bark with a sharp pointed knife, before the splitting of the stock.

2d. As after the leaves are grown it is not expected to use scions from a distance, but to cut them out of the orchard as wanted, be sure in selecting the grafts to cut them in such manner as to always take the bulge, between the year's growth, to shave and set in the stock, as in that joint or bulge, between the years growth, the wood is curled, open and porous, to receive the sap readily from the stock, and such scions will grow and flourish—when it taken from any other part of the twig they would not grow.

3d. The clay should be very fine and tough, and pressed and bound water tight round the stock below the split to retain all the sap that oozes out to support the graft.

By strictly adhering to this German science I have grafted several apple trees as late in the season as the latter part of June, that flourished and grew well, and are the best of bearing trees.

From all the experiments that I have tried in raising orchards, I would advise setting out the trees, and seeing a sample of their fruit before grafting, as all the best kinds of apples were at first natural, and perhaps by such a general trial some better kinds may appear than yet known.

I would also advise in grafting such bearing trees, to only take off half the top in one sea-

son. I have often taken off the whole, and if the season is wet they have done well, but if the season proves hot and dry, the trees generally die, or the sun kills the bark on the south sides of them, and then they are ever after defective; a rot takes place, and such trees generally blow down.

I have also observed that apple trees grow and bear the best when planted beside a stone wall, more especially those late seasons of great drought, that in parts of the country where the fences are generally of stone, abundance of apples might be raised without the trees incommoding the plough, and where there is only one row of trees across a field they may be planted within 15 or 20 feet of each other. In planting trees by a wall I would recommend as much as may be, to plant them on the north sides to keep the blossoms back and secure from the late frosts.

SAMUEL PRESTON

Stockport, Pa. Oct. 19, 1822.

FOR THE NEW ENGLAND FARMER.

FROM A CORRESPONDENT IN MAINE.

Mr. Editor,

I have been taking a tour of a few weeks, from the tide waters of the wild and turbulent Androscoggin, along its banks to the high lands of Maine. It was a novel sight, when I obtained any view of the river, to contemplate its banks, and the rocks in its bosom, covered and heaped with mill logs: This I have witnessed sixty or seventy miles from its mouth. The mill men there depend entirely on a freshet to waft their lumber down. There has not been any of sufficient height this season, and mills that would cut two hundred thousand feet of boards a day have done nothing for the season.

The banks of this river are high and forbidding, excepting below stupendous falls, where the water seems to rest from its labor. It is here that we find the intervale, made, or alluvial land, which bears a heavy and almost certain crop of almost every species of vegetable. The intervale at Durham is extremely beautiful; so is the extensive one at Jay Point, second to none I ever saw, excepting the Ox-bow at Newbury, Vt. One farmer owns 300 acres of land, under improvement, and can easily cut 200 tons of hay in a season. He tells me the made soil is from six to thirty feet deep. As you recede from the sea-board, clay almost entirely disappears. The soil of the high lands is generally of yellow loam, with a gravelly bottom, and is excellent for grazing. Bailey, an almost certain crop on our sea-board, was fine this year. Rye, through the country, a middling crop. Wheat, miserable, that lurking enemy at the root destroyed many fields entirely; it is a great desideratum with the farmer to find a remedy. Oats, a great crop. Potatoes, on the sea-board, good; on the high-lands, very much stricken with rust, though nearly a common crop. Buck Wheat produces well, and I was pleased that provident farmers had sowed it in sight of their bee-hives. Notwithstanding the despair of the first week in July, I am told there has not been so great a crop of hay for

twelve years. The fall feed never was better. In the new settlements, Clover Seed is a staple article of exportation. It was excellent this year. In this fine grazing country, they are now gathering their droves, mostly of young cattle, for the Massachusetts market. It has been a choice season for the dairy women. Their cheese, though not always equal to the Rhode Island, is not far inferior. Their butter stands unrivalled. I have had the honor of visiting a number of dairy rooms in the neighborhood, and from their reports can come pretty safely to this result, viz. That from eight good cows they have averaged a ton of butter and cheese this season. Mr. Thompson, of this place, has made over a ton, and 1000 lb. of his cheese is of new milk, and looks very fine. From his statements, and those of others, I have come to the above-mentioned ratio. There are nine farmers in this neighborhood whose amount of stock in cows is 33 cows. They have therefore made eleven tons of butter and cheese this season. Mr. Ira Thompson, of this place, has raised an apple weighing 25 ounces, and measuring 15 1-2 inches in circumference. The harvest of apples was never so great. The young orchards here are rapid of growth, and bending to the ground with fruit. A number of thousand bushels of the New York russets have been transported from this place and Turner to Hallowell, for the New Orleans market.

SPECTATOR.

Livermore, Oxford Co'y. Oct. 23, 1822.

FACTS AND OBSERVATIONS RELATIVE TO AGRICULTURE & DOMESTIC ECONOMY.

ON REARING CALVES.

Boil one quart of flax seed in six quarts of water for ten minutes, and it will become a good jelly when cold. Give this jelly to calves with hay tea, three times a day. Mr. Thomas Crook, a writer in the 5th vol. of the Transactions of the Bath Society, asserts that he weaned a great number of calves with this composition; and adds, "My calves are kept in a good growing state, and are much better than my neighbors that are reared by milk—they do not fall off so much when they come to grass."

TO MAKE HAY TEA FOR CALVES.

Take about a pound of red clover hay, well got in, and six quarts of clear spring water: boil them together till the water is reduced to four quarts; then take out the hay and mix a pound of barley, oat, or bean meal, amongst a little water; put it into the pot or chaldron while it is boiling, and keep it constantly stirring until it is thickened. Let it cool, then give it to the calf, adding as much whey as will make a sufficient meal. This is a cheap way of rearing calves, and the valuable article of milk may be saved for other purposes.

American Farmer.

DIRECTIONS FOR FEEDING CALVES.—FROM REES' CYCLOPEDIA, &c.

Where it is the custom to rear calves with skim-milk, it should always be boiled, and suffered to stand until it cools to the temperature of that given by the cow, or in a trifling degree more warm, and in that state given to the calf. Milk is frequently given to calves when warmed only; but that method will not succeed so well

as boiling it. If the milk be given over-cold it will cause the calf to purge. When this is the case, put two or three spoonfuls of rennet in the milk, and it will soon stop the looseness. If, on the contrary, the calf is bound, bacon broth is a very good and safe thing to put into the milk. One gallon, or rather more, of milk per day will keep a calf well till it be thirteen weeks old. A calf may then be supported without milk, by giving it hay, and a little wheat bran once a day, with about a pint of oats. The oats will be found of great service, as soon as the calf is capable of eating them, in promoting its growth. The bran and oats should be given about mid-day; the milk in equal portions, at 3 o'clock in the morning, and 1 in the afternoon. But, whatever hours are chosen to set apart for feeding the calf, it is best to adhere to the particular times, as regularity is of more consequence than is generally supposed. If the calf goes but an hour or two beyond its usual time of feeding, it will feel uneasy, and pine for its food.

Calves reared in this manner are to be enticed to eat hay, or some other similar material, as early as possible; and the best way of doing this is to give them the sweetest hay in your possession, and but little at a time. Turnips or potatoes are very good food as soon as they can eat them; and they are best cut small and mixed with hay, oats, bran, and such articles, at the time of their being given. When bacon or pork is boiled it is a good way to preserve the liquor or broth, and mix it with milk for the calves.

It has been suggested that it is sometimes a good convenient plan, to bring up calves under a sort of foster mother: an old cow with a tolerable stock of milk, will suckle two calves, or more, either turned off with her, or at home, keeping them in good condition, until they are old enough to shift for themselves; they ought to suck the first of their mother's milk, for two or three days, although many are weaned without ever being suffered to suck at all. Calves, whether rearing or fattening, should always suck before milking, the cow being milked afterwards, as the first and thinnest of the milk is sufficiently rich for them. Old milk often scours very young calves; but the effect generally goes off without any ill consequence. Skimmed milk and second quality of flour are sometimes made use of. The large short horned breed of calves mostly consume, daily, at three meals, three quarters of a pound of flour each, boiled up in skimmed milk or other liquid.

In the Rural Economy of Norfolk, it is remarked by Mr. Marshall, that some farmers raise their calves all the year round. Others rear in winter only. In general, however, they begin early in winter to rear their calves, some as early as Christmas. No distinction is made between males and females, both being equally objects of rearing, and are both occasionally subject to castration, it being a prevailing custom to spay all heifers intended to be fatted at three years old.

Among other substitutes for new milk, the method proposed by the duke of Northumberland is to take one gallon of skimmed milk, and to about a pint of it add a large table spoonful of molasses, stirring it till it is well mixed; then take an ounce of linseed oil cake, finely pulverized, and with the hand let it fall gradually in very small quantities into the milk, stirring it

in the mean time with a spoon or ladle, until it be thoroughly incorporated; then let the mixture be put into the other part of the milk, and the whole be made about as warm as new milk, when it is first taken from the cow, and in that state it is fit for use. The quantity of oil cake powder may from time to time be increased as occasion may require, and as the calf becomes inured to the flavor of it.

The method of weaning calves is thus prescribed by an English writer. The most suitable season for that business is the early part of the spring, as such calves as are weaned at a late period seldom attain any great size. Having a cow suited to the purpose, which drops a calf, let it be suckled in the usual mode, till it hath completed the third week of its age, when instead of turning it to the cow, it is to be suckled by thrusting its head into a pail of new milk, and the finger of the person who directs the business is to supply the place of a teat. At first the calf may be rather awkward at sucking the finger, but this will soon become familiar, and after a while a lock of hay may be substituted for the teat; and as the calf advances in age it will drink the milk without assistance. At the season when the calf is thus weaned from the teat, it ought to be turned abroad, in the day time, into a small close or orchard near the yard, where there is a good bite of grass. As there will, generally, be more than one calf weaned in a season, they will each be company for the other, and become, in a short time, reconciled to their situation. This pasture should be at some distance from that wherein the dams are turned, and there should be neither ponds nor ditches, nor any other annoyance, which may endanger the lives of these youthful animals; and in order to habituate them still more to their pasture, their pottage should be carried clean to them at their feeding hours. For the first month or six weeks the calves ought, every night, to be brought out of the meadow and lodged in pens; but after this time, they may be left in their pasture, as well in the night season as in the day, and at this time their food may be lowered by degrees, till it be reduced to water only, for when the calves get to the age of twelve or fourteen weeks, they will no longer require the aid of this sustenance, but will be able to satisfy their appetites by grass. Care, however, must be taken through the summer that they be frequently shifted from one pasture to another, in order that they may be kept in good flesh, and enabled to grow with celerity. In the latter part of September the calves should be taken into a yard; and if they were allowed the indulgence of a small close by themselves, it would be still better. And here their taste should be gratified with the best and sweetest hay that can be procured, with an outlet on a dry pasture, where, in fine open weather, they may be permitted to enjoy themselves; and it would redound greatly to their welfare, if, on the approach of winter, a shed was to be erected for them to repose in during the night, and for shelter in tempestuous days. So essential are warmth and good living to young animals of every description, that the care, which has been taken of them in their early days will be manifest in every state of their future growth. At two years old the heifer may be suffered to take the male, but it would be still better for the cow, and more to

the interest of the farmer, if this was not permitted till the animal was three years old.

Mr. Beatson, in a useful communication to the British Board of Agriculture, observes, "that the only reason he can assign why calf pens should be within the cow-house is, that it saves a little trouble to the dairy maid, by having a shorter distance to carry the milk. In general, however, it is a plan not to be recommended, as every person, who has had any experience among cows must know how naturally and forcibly a newly calved cow expresses her attachment to her calf; with what care and anxiety, if permitted, she licks it all over, and uses every exertion to protect it from injury; how the tender calf clings to its affectionate mother, as if sensible that to her alone it can trust for protection; and yet the poor helpless creature is dragged away, and placed, perhaps, within its mother's view, or at least within her hearing, as if on purpose to augment her sufferings. Its doleful cries keep alive the pangs of the unhappy cow; she struggles to break the chain that binds her fast, and seems restless and uneasy whenever approached. In such a state of agitation it is impossible she can ever feed well, or give that quantity and quality of milk she would otherwise furnish. Where there are many cows kept, and perhaps several of them lately calved, a single calf may keep them all in this restless state; to remedy which the best way is to have the calves at such a distance, or at least so thick a wall between them that the cows cannot hear their cries. The cow will then soon forget her calf, and will both feed and milk the better for it; therefore they should be as near as may be without being liable to the above objections.

The principal thing to be observed in the construction of calf pens is the laying of the floor. This should be made of lath or spars, about two inches broad, laid at the distance of an inch from each other upon joists, so as to make the floor one, two or three feet from the ground, as the situation will admit. This not only keeps the calves quite dry, by allowing all the moisture to pass immediately away, but admits fresh air below the bedding, and thereby preventing that unwholesome disagreeable smell too often found among calves. The place below the floor should be frequently cleaned, as well as the floor itself, whenever it becomes wet or dirty; but it is not right to allow the litter to increase to a great thickness, otherwise the moisture will not so easily pass through. Calf-pens are, however, too often made without this sparred floor, and the fresh litter is always laid on the old, till the calves are removed, which is a slovenly practice, and not by any means to be recommended.

Dr. Willich's Domestic Encyclopedia states that "in order to make calves fine and fat, the best and most efficacious way is, to keep them as clean as possible, by elevating the coops in such a manner that the sun may not have too great power over them, and to such a height above the level of the ground that their urine may pass off; by giving them fresh litter every day, and by suspending over the coop a large chalk stone so that they can easily lick it. Besides this, it is usual to bleed them when they are about a month old, and again just before they are slaughtered; which practice contributes in a considerable degree to the beauty

and whiteness of the flesh, and is therefore more frequently repeated by some persons; but this is not altogether necessary; twice bleeding being fully sufficient for that purpose, in the opinion of the most experienced breeders.

A METHOD OF MAKING GOOD BUTTER FROM THE MILK OF COWS FED ON TURNIPS.

Let the vessels which receive the milk be kept constantly clean, and well scalded with boiling water. When the milk is brought into the dairy, with every eight quarts mix one quart of boiling water, and then put it up to stand for cream.—*Hunter's Geographical Essays.*

A METHOD OF PRESERVING CREAM.

Take twelve ounces of white sugar, and as many grains of finely powdered magnesia, and dissolve them in a small quantity of water, over a moderate fire. After the solution has taken place, twelve ounces of new cream should be immediately added, and the whole uniformly mixed, while hot. Let it then gradually cool, and pour it into a bottle, which must be carefully corked. If kept in a cool place, and not exposed to the air, it may be preserved in a sweet state for several weeks and even months.

Domestic Encyclopedia.

HOW TO SAVE HORSES FROM BURNS ON FIRE.

Horses are frequently burnt to death when barns or stables are on fire, owing to the impossibility of leading or driving them out of the building, while their eyes are dazzled by the blaze. But we are assured that by simply covering their eyes with a bag, a coat, or a pocket handkerchief, they may be led out of danger without trouble or difficulty.

METHOD OF PRESERVING YOUNG PLANTATIONS OF TREES FROM BEING INJURED BY HARES OR LAMBS—BY WILLIAM PATTENSON, ESQ. OF BORDEN, KENT.

From the Transactions of the Society for the Encouragement of Arts, &c.

Hares, rabbits and rats, have a natural antipathy to tar; but tar, though fluid, contracts (when exposed to the sun and air for some time) a great dryness, and a very binding quality; and, if applied to trees in its natural state, will occasion them to be bound. To remove this difficulty, tar is of so strong a savour, that a small quantity, mixed with other things, in their nature loose and open, will give the whole mixture such a degree of its own taste and smell, as will prevent hares, &c. from touching what it is applied to.

Take any quantity of tar, and six or seven times as much grease, stirring and mixing them well together; with this composition brush the stems of young trees, as high as hares, &c. reach, and it will effectually prevent their being barked. I believe, if a plantation of ash (which they are very fond of) were made in a rabbit-warren, this mixture would certainly preserve it. These animals do great mischief amongst flowering shrubs, and are particularly fond of Spanish broom, Scorpion senna, and evergreen Cytisus. I have had those shrubs eaten down to a stump; but, as the mixture cannot be conveniently applied to them, I have enclosed their branches with new tar twine, putting it several times round the shrub, which has had the desired effect. Tar twine, by being exposed to the air and rain, will lose its smell, conse-

quently must be removed as occasion requires, but the mixture is always to be preferred, where it can be used.

It is probable that the abovementioned composition would preserve young trees in nurseries from the depredations of the field mouse, which are often fatal to young fruit trees in many parts of the United States.

Ed. N. E. Farmer.

SCAB IN SHEEP.

Every part of a sheep's body is liable to be attacked with this disease, which may be radically cured if attended to. It is more obstinate on the lips and nose, than any where else, because the animal rubs those parts while eating. The cheapest and simplest remedy, is an ointment composed of three parts of grease to one of turpentine.

FISH, FOOD FOR SHEEP.

It is a fact, though not generally known, that sheep will greedily eat any kind of salted fish, whether dry or pickled, although dry seem the most suitable for them; and it is found by experience that sheep that have as much fish as they can eat are always healthy, have good lambs, and do not loose their wool; and require much less other food. It is not expected that farmers remote from the sea-shore can afford their sheep as much fish as they would eat; but, if they give them fish instead of giving them salt, they will find a great advantage. Smoked Alewives and Herrings are most convenient for them; larger fish should be cut or broken in small pieces. The cheapest kinds of fish, such as scale of all kinds, broken, refuse, and even those that are partly damaged, if they are only salt, will answer the purpose.

It is generally the case with herring catchers that they are obliged to cull out and throw away great numbers, sometimes half they take, because they are to bear inspection: such might be salted and smoked or dried in the sun, put up in dry casks, afforded at a low price—by which means, thousands of barrels might be saved which are now suffered to rot on the shores.

TO PRESERVE POTATOES WHICH ARE FROZEN.

Cover them, while frozen, with two or three feet of sand or earth, and let them remain till thawed. The watery part of the potatoe, when converted into ice, occupying a larger space, removes the solid parts to a greater distance from each other, occasioning thereby a partial disorganization which, like animal inflammation from cold, will end in putrefaction, unless a low temperature is maintained until the solids gradually regain their former powers.—*Farmer's Mag.*

They may be thawed in cold water, which will take out the frost without injuring the vegetables.

Ed. N. E. Farmer.

Live constantly in the unshaken belief of the overruling Providence of an infinitely wise and good, as well as Almighty Being; and prize his favor above all things.

Accustom yourself to temperance, and be master of your passions.

Be not too much out of humor with the world, but remember, it is a world of God's creating, and however sadly it is marred by wickedness and folly, yet you have found in it more comforts than calamities, more civilities than affronts, more instances of kindness towards you than cruelty.

From the *Christian Register* of November 1.

GARDINER LYCEUM.

MR. EDITOR—I observed in the *Hallowell Gazette* of the 12th ult. an address to the public, from the Trustees of the *Gardiner Lyceum*. The knowledge that such an institution is about to be established, cannot be too widely diffused. That our colleges are useful and necessary to those who intend to pursue one of the learned professions cannot be denied; but they are by no means calculated to supply that particular kind of knowledge which is necessary to the Farmer and Mechanic.

The utility of an institution like the Lyceum will be best shown by a few extracts from the address.

The small number of mechanics acquainted with those principles of natural philosophy, upon which the successful operation of their arts depend, has been long a subject of regret. Artists, it is true, are found in various departments, who, by means of uncommon natural talents, are able to acquire the knowledge of those scientific principles, which are most needful to them; but those to whom nature has been less liberal, can only execute in the way in which they have been taught, and while they adopt the rules and recipes of their predecessors, they are obliged to perform much unnecessary labor, because they are unable to distinguish the essential from the accidental parts of their processes. And even those of superior endowments are obliged to spend much labor in acquiring principles, which are among the first rudiments of a regular education. Nor have our farmers hitherto had that knowledge which would enable them to improve the powers of their soil, or the machines necessary for cultivating it, and preparing their produce for the market. The knowledge necessary for these descriptions of persons is confined to colleges; but science is there taught, not to persons who are to make a practical use of it in after life, but as part of a course of general education to those who are destined for the liberal professions. The details of the practical application of science to the particular arts would be altogether inconsistent with the objects of these institutions. Neither could those who are to support themselves by manual labor, spare the time or meet the expense of a collegiate course, with its long train of preparatory studies, particularly when a large part of that course would not only be useless, but would serve to give them a distaste for their future pursuits in life.

The practical utility of science cannot be doubted, in an age where its investigations have produced such astonishing improvements as in the present. There is scarcely an art which has not directly or indirectly received from it important services; for science must necessarily be the foundation of every art. Not that the arts originate in the speculations of the philosopher, or cannot be practised without an acquaintance with science. On the contrary they frequently owe their beginning to accident; and the knowledge of the art is but the knowledge of a few insulated facts. These facts, observed by the man of science, lead him to an investigation of their nature, and the laws according to which they are produced. He discovers what is necessary and what is accidental in the process, and thus infers an easier and cheaper mode of arriving at the same result. Chemistry, as a science, has scarcely existed half a century, and yet no science can so proudly boast its contribution to the arts. To many trades, it is absolutely necessary, and to almost

all, highly beneficial. The tanner, the bleacher, the dyer, the druggist, the manufacturer of pot and pearl ashes, of soap, of copperas, and all the salts of commerce, of spirituous and fermented liquors; all these, and very many more, find their arts dependent upon chemical processes. The mason needs chemistry to mix properly the ingredients of his mortar, the blacksmith to temper his edged tools, and even the baker to ferment his bread. It is true, these arts may be, and are successfully practised by attentive and intelligent persons, ignorant of science; but a knowledge of chemistry would enable men of an inferior class of mind to become skilful; would make the success of all more certain; enable them to investigate the causes of occasional failures, and to guard against their recurrence.

Agriculture, too, depends much upon chemistry. It is the business of this science to investigate the nature of soils, the causes of their fertility or barrenness, to ascertain the composition of manure, and the kind best suited to give fruitfulness to each kind of soil. The experience of Lavoisier, who in a few years doubled his crops, is sufficient to prove the utility of chemistry, when applied to the cultivation of the earth.

With a view to furnish to farmers and mechanics the education here represented as so useful, the Gardiner Lyceum has been established; and the course of study will be arranged with a particular reference to the wants of those classes, for whose particular benefit it is designed. As soon as a suitable apparatus can be procured, lectures will be given upon the sciences there taught; and the application of those sciences to the arts will be illustrated as fully as the nature of the lectures will admit. As fast as the funds of the institution will allow, models will be procured of the best machines employed in the useful arts. Specimens will likewise be collected of the natural productions of the country, as opportunity offers; and they will be deposited in a cabinet in the Lyceum.

Candidates for admission to the Lyceum will be required to produce certificates of good moral character, and will be examined in the four fundamental operations of arithmetic: addition, subtraction, multiplication and division, both upon simple and compound numbers, and in reduction. It is also very desirable that English Grammar should be understood by those entering the Lyceum; and although the trustees do not at present consider it as an indispensable requisite, yet they hope it will have been studied by persons applying for admission. The studies in the Lyceum will be—

For the first year—Arithmetic, Algebra, Geometry, Trigonometry, Mensuration of Surfaces and Solids, and Book-Keeping.

In the second year—Surveying, Navigation, Mechanics, Hydrostatics, Pneumatics, and Chemistry.

No student will be required to attend to all the branches of instruction for the second year, but only those which are best adapted to his future wants. He will also be instructed in the practical application of the knowledge thus acquired to the particular art which he is to practice. Two years will complete what is deemed an essential course; but instruction will be afforded to those who wish to continue their studies another year.

The studies of the third year will be—

Other branches of Natural Philosophy, the higher branches of Mathematics, Natural History, and the first volume of Stewart's Philosophy of the Mind.

There will be regular exercises in English composition; and each Monday morning all the classes will be instructed in the principles of natural and revealed religion.

The trustees consider the location of the Lyceum in the town of Gardiner as peculiarly fortunate, from its central position, on a navigable river, in a populous neighbourhood and fertile country, where commerce is continually extending, and in a town possessing uncommonly fine mill privileges, and which already offers to the student in mechanics the exhibition of a greater variety of machinery moved by water than can be found in any other town in the state.

[The Lyceum was incorporated at the last session of the Legislature. The trustees are about erecting a stone edifice for the accommodation of the students, and the institution will go into operation some time in January next, under the superintendence of the Rev. Benjamin Hale.]

"The trustees conclude their address with expressing their confidence, as they are engaged in an object calculated to meet the wants of a state which possesses all the requisites for becoming great, and distinguished in agriculture, manufactures, and commerce, that they shall not want the support and encouragement of the public. They are engaged in no private enterprise. They expect to profit no particular class of men, but to aid those who form the bone and sinew and muscle of the body politic. They aim at the public good, and hope for the public patronage."

F.

From the *National Aegis*.

MINERALOGICAL.....No. I.

The objects of an enlightened system of agriculture are philosophical, so far only as they follow nature. Art may plant, industry may water, but nature gives the increase. The plough and the cart may have been used, according to the best modes of improvement, and yet the tracts of land on which they have been employed, may produce but miserable crops. We seldom have the charity to attribute the sterility of farms, to any thing but the indolence of the proprietor; when, perhaps, the true cause is in the nature of the soil itself. The husbandman may waste the sweat of his brow, and the toil of his hands for years, by perseverance in the same course which, with his neighbours, gives a rich reward. To remedy any evil, it is first necessary to seek out its cause. Now, a little of that knowledge derived from books, against which a prejudice has been so unreasonably entertained, would inform the farmer that the reason why his crops were not as good as another's, must be, that he did not adapt the plants to their proper soil. He would learn that the same labour which has been bestowed without benefit, would, if properly directed, have filled his barns with abundant harvests, and converted his barren plains into a garden.

How far the same laws regulate vegetable and animal economy, has not been exactly determined. Certain it is, that there is an analogy in the laws, which regulate both kingdoms.

If the stock of the husbandman requires feeding, and as he would not give his oxen sulphuric acid for drink, or arsenic for a baiting, neither could he treat his field of rye or wheat in the same manner. Those poisons which are most deleterious, belong to the classes of Minerals. All the metals which are so numerous and so widely disseminated, are highly prejudicial to animal life, and that they are injurious to plants, may be inferred from the facts, that, districts in which mining is pursued to the greatest advantage, where the greatest wealth abounds in the bosom of the earth, are barren and sterile on the surface.

It is an hypothesis now generally received by writers, that different plants, require different nourishment. If the growth of the forest is succeeded, not by the same tree, but by a species totally different from the former occupant of the spot, it is believed to be, from a wise provision of Nature, requiring that the plant whose peculiar food was consumed, should seek a more favorable situation. Most persons who are observant of the phenomena exhibited around them, must have remarked the daily changes taking place in the growth of our forests. The lofty pines, which at one time formed the most numerous variety of our timber trees, have almost disappeared, and instead of them, the oak and the walnut have sprung up and occupy their places in the woods. The explanation of this fact is not difficult upon the theory to which we have alluded. Let us suppose a soil, constituted of resinous, nitrous, and alkaline earths. If the resinous particles existing in the soil are the food of the Pine and necessary to its life and vegetation, it is evident that where these particles shall have been exhausted by the continual draughts made upon them, for the supply of so many roots and branches, the individual can no longer exist.* If young trees of the same species should rise from the seeds deposited near the parent trunk, they must soon perish, from the want of the support essential to their healthy state.—The soil according to the supposition still contains nitrous and alkaline particles. Assuming, that the first of these, are the proper nourishment of the Walnut, that tree will flourish upon the spot where the Pine once stood, until these are exhausted, when it must share the fate of its predecessor. Two of the constituent parts are now consumed, on the third the Oak may subsist and strike its roots deep and shoot its branches high. This exemplification is selected as a familiar one. The application is obvious to other examples. It shows the close connection that should subsist, between the practical and the scientific man. It evinces conclusively the beneficial results that will attend the prosecution of Chemical and Mineralogical pursuits. If the wheat is blasted, or its produce be light and ill-conditioned, the fault is more likely to be found in some quality of the soil prejudicial to that grain, than in some harmless insect or innocent

shrub. If the food necessary for the Rye be exhausted by a single crop, it would be folly to expect a second to thrive on the same field. If properties noxious to the Rye, are beneficial to the Indian Corn, then, the commonly practised succession, which placed that grain before the other, is founded on sound reason. It is true, that experiment has not, as yet, rendered these principles "doubly sure;" but this should only be an incentive, urging the curious to investigations so important to the good management of rural concerns.

Men who have not been accustomed to scientific pursuits, are usually frightened and discouraged, by their apparent abstruseness and difficulty. To such, abstract studies must be divested of some of their rigor, or they will never be persuaded to follow them. It cannot be expected, nor is it wished that the intelligent, practical farmers of the country should waste their time, and perplex their minds, with deep inquiries into Mineralogy, or be able to take rank with the Werners, the Hays and Cleavelands, who have adorned and improved that department of knowledge. But it is desirable that they should be acquainted with so much of it, as to be able to distinguish the several mineral productions of their lands and be acquainted with their several properties. The practical agriculturist, is ignorant of many sources of revenue which he might possess. His lands may contain treasures, of which he has never dreamt. His plough daily turns up substances, which would be valuable, were he only acquainted with their worth. Those tracts which are parched by the summer sun, and which, to his eye, are sterile and barren, may contain hid in their bosom, mines and metals which would amply repay the toil and expense of exploring them.

In recommending Mineralogy to attention in its connection with agriculture, it will be proper to state the grounds of the faith that is in us, of its usefulness. This shall be attempted in a subsequent number. A FARMER.

From the Hallowell Advocate.

In a late Advocate was published a new Rule for gauging casks, given by SAMUEL PRESTON, Esq. of Stockport, Pennsylvania. This rule was first published in the *New England Farmer*, and is recommended by its author as useful to the farmer in ascertaining the quantity of cider he makes, and exceeds in accuracy and brevity any other rule before employed. The rule is as follows:—

1. Multiply the mean diameter of the bung and head diameter by itself.
2. Multiply the product by the length of the cask.
3. Multiply that product by 34.
4. Strike off four decimals, and you will have the true contents in gallons and decimal parts of a gallon.

The admeasurements are to be taken in inches and tenths of inches.

The author of this rule gives no explanation of it; but calls upon the mathematical student to give an explanation or demonstration of it.

As the reasons of all parts of the rule may not be readily hit upon, and to know the rationale on which it is founded may be gratifying to those who may happen to make use of the rule, the following explanation is given, adapted to any common understanding.

As necessary to the explanation of the rule, we premise the following principles—to obtain the cubic or solid contents of a regular body, you must first get the superficial contents of a base of it. For example, to obtain the cubic contents of a parallelepipedon, or, in other words, of a square stick of timber of equal size from end to end, you first get the superficial contents of one end by multiplying one side of the square into itself; then multiply the superficialities of the end by the length of the stick, and you will have the cubic contents in the same denomination of measure as you have employed in the previous work. If the stick be of unequal dimensions, you must take the mean of the diameters in different parts, and from this mean diameter obtain a mean superficialities, and multiply this superficialities by the length of the stick for the solid contents.

To apply these principles to the first step in the above rule. A cask, being a cylinder of unequal diameter, you will first take the mean of bung and head diameter for the side of a square, equal to said mean diameter. You then multiply this mean diameter into itself, and this gives you the superficial contents of a square made by the mean diameter. Then the 2d step in the rule, viz. multiplying this superficialities by the length of the cask, gives you the solid contents of a parallelepipedon (of which the form of a square stick of timber is an example) whose base or end is a square of the mean diameter of the cask, and of the same length as the cask.

The reason of the 3d step in the rule is not so apparent as the preceding steps, and requires a more particular explanation—and as the 3d and 4th steps are so connected in principle as to be incapable of explanation separately, we shall consider them together.

It must be recollected that the process thus far explained, has given us the solid or cubic contents of a square stick of timber, whose diameter is equal to the mean diameter of the cask whose contents are to be ascertained, and whose length is the length of that cask; and that the object to be obtained by the 3d and 4th steps is to get the cubic contents or capacity of the cask in gallons and decimal parts thereof. Now it is evident from inspection that a square stick of timber, whose diameter is the mean diameter of the cask and whose length is the same must be greater in solid contents than the cylinder whose diameter and length is the same. Then we must reduce the contents of the square stick of timber already obtained to those of the cylinder of the same diameter and length—that is, of a cylinder whose diameter is the mean diameter of the cask. Now the cubic contents of the cylinder and the square stick have the same proportion to each other as the superficialities of their ends, viz. the circle and square, their diameters being the same. The superficial contents of a circle are to the contents of a square whose side is equal to the diameter of the circle as 7854 decimals to unity. Now then, we want to reduce the contents of the square stick to those of the cylinder. Therefore multiply the product of the 2d step by 7854 decimals and cut off four decimals in the product, which is the same thing as to multiply by $\frac{7854}{10000}$, this being the vulgar form of that decimal; as in a vulgar fraction, you always in multiplication multiply by the numerator, and divide by the

* Note by the Editor of the N. E. Farmer.—Resinous particles are formed in plants during the process of vegetation, being extracted from hydrogen, one of the chemical constituents of water. "All kinds of vegetables, when assisted by the rays of the sun, have the power of decomposing water; during which decomposition the hydrogen is absorbed, and goes to the formation of oil and resin in the vegetable."

Parkes' Chemical Catechism, p. 54, 10th Ed.

denominator. This done, you would have the cubic contents of a cylinder equal to the cask in cubic inches. To bring this denomination into gallons, it would be necessary to divide by the number 231, this being the number of cubic inches in a Wine gallon.—But to save this long process of multiplication and division, adopt this rule, viz. *to multiply by the Quotient of a multiplier divided by the divisor by which the product produced by such multiplier is proposed to be divided, and you will have the same result.*

Now 34 is the Quotient of 7854 divided by 231. Therefore multiplying by 34 produces the same result as to multiply by 7854 and dividing by 231—taking care in the product to cut off as many decimals as there are in the multiplier 7854. And these are the reasons for the 3d and 4th steps of the rule. And the result is the contents of the cask in gallons and decimal parts thereof—Thus we have the *reasons* of the rule

HHD. ALIAS & BELLS.

From the American Farmer.

TO CURE BACON.—*Virginia vs. Burlington.*
Richmond Co. (Va.) Nov. 24, 1824.

MR. SKINNER—Having seen in the 20th No. of the 3d Vol. of your American Farmer, a refusal of one, who has been specially called on to communicate his knowledge or mode of curing Burlington hams, I cannot longer refrain from giving such information as I possess, in curing hams according to our Virginia mode, as practised by me for many years, and which on trial I am induced to believe, will be found fully equal, if not superior, to the Burlington, or even the celebrated Westphalia. This I do with pleasure, having no secret to preserve, being no “trucker or trader.”

My practice is as follows: first salt the pork by giving it a pretty good salting, and pack it away on boards or planks, with a slope sufficient to let the brine run off. In this situation it lies ten or twelve days, when it is taken up, and each piece wiped dry, with a coarse cloth, and to each ham is added a heaping tea spoonful of the best chrys-talized salt petre, by sprinkling over it, and rubbing it well in with the hand. It is then re-salted again, and packed away on planks or boards, laid horizontally, or in tight casks, if you have them convenient, as it may then be an advantage to retain or preserve all the brine you can: whereas the first brine I have found from experience to be of great injury, as it ends to putrescence, and should by no means be reabsorbed by the meat lying in it after being extracted by the salt; as I conceive it to be that which produces the bugs and skippers in the meat after it has been smoked. The time of putting on the salt-petre is of much more importance than is supposed by those who have not made the trial, for if put on at the first salting, the meat is always dry, hard, and too salt; but why it has this effect, I am not chymist enough to determine. On giving the meat a second salting I add to the salt as much brown sugar or molasses as will moisten or damp it, and as much of the common or red pepper as will give the salt quite a red appearance. The pods are first dried before a fire or on a griddle, and then pounded tolerably fine in a mortar. The meat then lies about 5 or 6 weeks when each piece should be rubbed well with hickory ashes, and hung up to smoke with the hook downwards, which prevents its dripping and thereby retains

its juices. The Liverpool sack-salt is what I have generally used, and I think it is much to be preferred to any other.

The smoke is generally made from chips raked up from the wood-pile, with a little of the dust, dotted, or rotten wood with it, to prevent a blaze or clear fire, and too great a heat, saw dust of hickory or oak is still better to make the smoke, to which is added two or three pods of the red pepper each day.

After it is sufficiently smoked, which it will be in five or six weeks, if regularly attended to, it is taken down and packed away in casks or boxes, with hickory ashes, covering the meat entirely with them, and between each layer is put some thin slips of lath or boards to prevent each layer of meat pressing down and touching each other, and in the course of the summer it is taken out and sunned once or twice.

If it is intended for exportation, bran is the thing to pack it in, for shipping, especially if it is intended for a southern market. By this mode of curing my bacon has got the reputation (by those who have eat of it) to be equal if not superior to any they have ever tasted. But I concur with Mr. Cox, the writer in your 20th No. of the third Vol. that “a great deal depends upon the nature of the flesh of the several breeds of hogs” and the manner of raising and feeding. From the experience which I have had I think a cross of one-fourth of the Chinese, on our common stock, which is a mixture of the English breed including the Parkinson, which we have among us, is the most delicate in flavour and taste, and easier to be raised and kept fat, consuming less grain. The meat of those which are suffered to feed in the fields and woods, with a little feeding with grain until they are put up to fatten, are far superior to those which are raised in the sty, and fed on grain and slops, as is the northern custom.—Their meat is much larger and coarser than ours, and may answer very well for salting and barreling up as pork, but by no means answers as well for bacon, being too coarse and strong in flavour. The manner in which our hogs are raised and fed, and their size, I consider the principal reason why our Virginia hams have been so much approved of, both in this country and in Europe. I have tried various ways to fatten hogs, after they have been put up for close fattening, but have never found any thing to equal Indian corn or meal; turnips, potatoes, peas, pumpkins &c. will do very well when they are first put up, but must be left off some weeks before they are killed, in order to harden their fat, and give it a superior flavour, by using Indian corn alone, with a little salt water, or a salt herring once or twice a week.

To make bacon of the most delicate flavour, the hogs should not exceed 160 lbs. in weight, nor 21 months in age, and it is for this reason, and the great economy in raising and feeding, as well as preventing their becoming mischievous and troublesome on a farm, that I approve of Col. Taylor's system of killing every hog on the farm every year that is ten months old and upwards, except the breeders. I have followed this practice for about seven years, and have found a considerable profit in it as hogs kept over two winters, are very unprofitable, and their flesh by no means as delicate and sweet. Hogs from 10 to 21 months old, with a little more than the ordinary keeping with us (which is

very ordinary indeed, as we generally leave them much to prog and shift for themselves will weigh from 120 to 130 lbs. and the sweetest and most delicate flavoured hams will not be found to exceed from 10 to 15 lbs. in weight even of hogs of their age, and when older they are much coarser and less savoury.

These, Mr. Skinner, are my ideas, obtained from experience and thrown together in a very home-spun manner, and should they on trial be found to please the palates of others and be generally adopted by them, I may be benefitted instead of injured, as was apprehended by a Burlington dealer, for as I sometimes travel from home, and am fond of good bacon, I may the oftener get a cut of ham after my own mode of curing. And with very great respect, and my sincere wishes for your success in your very useful paper,

I am your most obedient,

JNO. DARBY.

THE FARMER.

BOSTON:—SATURDAY, NOV. 16, 1822.

ADVANTAGES OF TAKING AND PATRONIZING THE NEW ENGLAND FARMER.

“There is that withholdeth more than is meet but it tendeth to poverty.”—This was a wise saying of the wisest of men. We trust, however that our agricultural brethren of New England do not intend to give *practical* comments on this text by withholding patronage from a paper devoted almost entirely and exclusively to their interests. This would be to lose dollars in saving cents; and to economize about as unprofitably as he does who but half manures his land, or allows but half the requisite quantity of seed when he sows his wheat, rye, clover, &c.

It is very true that many farmers, whom we should be happy to enrol on the list of our subscribers, may have a very good knowledge of their business, derived principally from experience; and although Dr. Franklin declared experience was a dear schoolmaster, yet it must be allowed that the said experience gives pretty thorough going lessons, and brings them home to men's business and concerns in such a manner that its admonitions are not easily forgotten. Dr. Franklin likewise said, in substance, that those persons who would learn nothing except what they were taught by experience, were *fools*. Now this is a hard name, which we hope will never be correctly applied to any individual farmer, at least within the compass of the circulation of our newspaper. But, *the cheapest way to gain knowledge is to take advantage of the experience of others*; and he who refuses to be taught by the experience of others, if not a fool, is certainly not *so wise as he might be*. Now the New England Farmer is intended to be a *record of the experience of husbandmen in every branch of agriculture and domestic economy*. That there will be faults and

* We believe Dr. Franklin's adage was, “Experience is a dear school, but fools will learn in no other.”

inaccuracies in this record is to be expected as long as error is one of the attributes of humanity. But we believe that we shall be able to give in this work more valuable information relating to the most useful and important of the arts, as well as the most extensive and noble of the sciences, than can possibly be obtained at so cheap a rate from any other source of agricultural knowledge. In making this assertion we hope not to be accused of arrogance. The Editor claims no merit but that which arises from industry and good intentions. But if we faithfully avail ourselves of the sources of information within our reach, and make a good use of the local advantages which Boston affords in obtaining the publications of different societies and individuals both in Europe and the United States, our paper cannot fail to prove an acquisition to any person who is engaged in agriculture or its kindred arts. Indeed the recipes, economical processes, &c. must make it a valuable *family book*, and if not exactly a "Cook's Oracle," it would be at least a good House-keeper's Companion, and in some instances it may aspire to the honor of being a "Young Farmer's Guide."

The New England Farmer, it should be recollected, is not an *advertising paper*, and as it is often necessary to give engravings, which are expensive, prompt payment, and a pretty large list of subscribers are indispensable requisites to its existence. It is moreover a *very cheap paper*. We give a subscriber for two and an half dollars, more matter than he could obtain in almost any other recently printed book [the New England Farmer may be considered a book, printed in weekly numbers] for ten or twelve dollars.

We not only give a great quantity of matter, in proportion to the price of our paper, but the quality is exactly that which must prove of the greatest utility to a farmer and his family.—With regard to the mode in which it has hitherto been conducted it behoves us to say but little. If we should speak favorably of our own labors we should be guilty of boasting; and if we should lament our deficiencies we might possibly be accused of affecting a degree of humility which we do not feel. We have been so fortunate as to procure the approbation of the Officers of the Massachusetts Agricultural Society, which we consider as the best reward of our past exertions, and the highest stimulus to our future efforts. We have no doubt but that, according to the old adage, "practice makes perfect," we shall be able to improve as we advance in our editorial career, and hope that our future numbers may better deserve the favor of the public than those which have already been well received by competent judges.

We have in contemplation some arrangements relative to our paper, which we conceive may enhance its value. Among others we propose

to give articles from the most approved authors relating to the diseases of cattle, horses, swine, sheep, &c. We may thus enable our subscribers, no doubt, in many instances, to save valuable animals, when attacked by disease. This may be the more advisable on account of our country's containing very few Farmers, or Veterinary Surgeons by profession. Every farmer must, in many parts of New England, be his own cattle-doctor, and it is hoped no farmer will take amiss some directions relative to a science of such indisputable, and almost indispensable utility. We hope in the present volume to incorporate some complete treatise on this subject, and shall take the advice of some scientific friends, as well as exercise our own judgment in selecting for republication, some work which will be plain, practical, and have no tendency to mislead, or to sanction dangerous or erroneous practice.

Some of our friends have solicited from us, information relative to various topics, connected with agricultural improvement. Amongst others we are requested to give articles relating to the *best mode of laying down ploughed lands to grass—the best manner of reclaiming salt marshes, and converting them into tillage land—the latest improvements in the manner of cultivating hops, curing and preparing them for market—the best, least expensive, and most expeditious mode of clearing new land, covered with timber, and reducing it to its most profitable state of cultivation, &c. &c.*—We shall give our own ideas on some of these subjects, and should be happy in being favored with the opinions of our correspondents on these topics. Perhaps our friend from Stockport, Pa. will give us his ideas relating to some or all of them. We court his correspondence, and set the higher value on his communications because they appear to be derived principally from personal observation—are the result of much experience combined with good sense. They are likewise written in that plain and perspicuous style which always ought to be the vehicle of science, although literature may perhaps sometimes require something more ornate and artificial.

We shall conclude this article with a word or two by way of answer to an objection which we have heard stated against some of the matter in the New England Farmer, and indeed against any precise or definite rules relating to husbandry. It is said that every man must be governed *solely* by his own judgment and discretion, because circumstances so alter cases, soils are so different, &c. that no two farms can be profitably cultivated in the same manner. General rules, however, are useful, although exceptions often occur, and every cultivator is expected to exercise his own judgment, to determine whether a particular case comes within a rule, or forms an exception to that rule. Besides, a great part of the matter found in the New Eng-

land Farmer, is not only derived from high authority, but is applicable in every case designated in the articles. For instance, cattle in Great Britain or Pennsylvania have generally the same or similar diseases with those of New England—steeps to prevent smut in wheat may be the same—hams may be cured and eggs preserved by the same processes, making perhaps a little allowance for a difference in the temperature of climates. And if horses will eat mangel wurtzel or sweet apples in England or Pennsylvania, they will not refuse them in Massachusetts.

Plumbago, or Black Lead discovered.—Mr. Charles J. Dunbar, of Concord, Mass. has discovered a mine or quarry of Black Lead, in the town of Bristol, N. H. He has exhibited specimens of this substance to Professor Dana, of Dartmouth College, Professor Gorham, of Harvard University, and other gentlemen who are versed in the science of Mineralogy. They all speak favorably of the specimens. Professor Dana states that those which were exhibited to him "are of the *very first quality*, and will make excellent pencils, and other articles for which this substance is employed. The specimens are far superior to the black lead found in Sutton, or in any other part of the United States, so far as I know—and equal, in every respect, to the celebrated ore of this substance found in Burrowdale, in England."

Plumbago, Black Lead, or the Carburet of Iron, has various uses, besides that of making pencils. It is used to rub over wooden machinery to prevent friction—for making crucibles and portable furnaces—it protects iron from rust, and on that account is rubbed on stoves, and various ornamental cast iron works, such as the fronts of grates, &c.

Murder.—On Saturday morning early, the body of Anthony Rogan, a young man, about 27 years of age, was found dead in Court-st. by the city watch; and the verdict of the inquest on it was, that he came to his death by wounds inflicted by some person unknown. One of the stabs entirely separated the jugular artery, and must have occasioned immediate death. He was a native of Ireland, and in the employ of Dr. Johnson, veterinary surgeon. He left his lodgings, in Bangs' alley, about ten o'clock in the evening; and undoubtedly repaired to the Hill, where he had a quarrel about three weeks before; and where he told a person on Friday he intended to go that night, and expected to be attacked by persons he named.

Three hundred dollars—one hundred by the city, one hundred by Dr. Johnson, and the other hundred by Mr. Thomas Kennedy—are offered for the detection of the murderer.—*Continued.*

We learn with regret, that the Cotton Mill, in Sutton, Mass. belonging to Mr. Asa Water— and improved by Messrs. Leland, Morse & Co. with the grist mill attached thereto, was entirely destroyed by fire, on the 5th inst. With the buildings a considerable quantity of yarn and cloth was also destroyed. The fire originated in the picking room; probably from the passing of some hard substance through the picker. Loss estimated at \$14,000.—*Providence Journal.*

The Cabinet Factory of Mr. Bradley of Alexandria, has been consumed by fire. Loss 12,000 dollars.

Benj. Bussey, Esq. and Amasa Stetson, Esq. have presented 50 dollars each, to the Penobscot Agricultural Society, to be expended in Premiums.

Harvard College.—The trustees of this institution have appointed Mr. NUTTALL curator of their Botanical Garden and lecturer on Botany in the University. This situation was vacated by the death of Professor Peck.

Mr. Nathan Flecher, of Bradford, made, in one day, working about 24 hours, twelve cider barrels.

SELECTED FOR THE NEW ENGLAND FARMER.

RURAL FELICITY.

O happy he! happiest of mortal men!
 Who far removed from slavery as from pride,
 Feels no man's power, nor cringing waits to catch
 The gracious nothing of a great man's nod;
 Where the field beggar bustles for a bribe,
 The purchase of his honor; where deceit,
 And fraud, and circumvention, dress in smiles,
 Fold shameful commerce; and beneath the mask
 Of friendship and sincerity betray.
 Him nor the stately mansion's gilded piles,
 Rich with whatever the imitative arts,
 Painting or sculpture yield to charm the eye;
 Nor shining heaps of massy plate enwrought
 With curious, costly workmanship allure.
 Tempted nor with the pride nor pomp of power,
 Nor pageants of ambition, nor the mimes
 Of grasping avarice, nor the poison'd sweets
 Of pamper'd luxury, he plants his foot
 With firmness on his old paternal fields,
 And stands unshaken. There sweet prospects rise
 Of meadows smiling in their flowery pride,
 Green hills and dales, and cottages embower'd,
 The scenes of innocence and calm delight.
 Where the wild melody of warbling birds,
 And cool refreshing groves, and murmuring springs,
 Invite to sacred thought, and lift the mind
 From low pursuits to meditate on God!

Turn then at length, O turn ye sons of wealth,
 And ye who seek through life's bewildering maze,
 To tread the paths of happiness, O turn!
 And trace her footsteps in the rural walk;
 In those fair scenes of wonder and delight,
 Where, to the human eye, Omnipotence
 Unfolds the map of nature, and displays
 The matchless beauty of created things.
 Turn to the arts, the useful pleasing arts
 Of cultivation; and those fields improve
 Your erring fathers have too long despis'd.
 Turn to that science, which in ancient time
 The mind of sages and of kings employ'd,
 Solicitous to learn the ways of God,
 And read his works in agriculture's school.

The following is a translation, by Dr. Darwin, of certain beautiful lines in Virgil's Georgics, on Ingrafting. They may form an excellent accompaniment to Mr. Preston's remarks on the same subject, which we have published on the first page of this day's paper.

Where cruder juices swell the leafy vein,
 And the young germ, the tender blossom stain;
 On each lopp'd shoot a foster scion bind,
 With press'd to pith, and rind applied to rind,
 So shall the trunk with loftier crest ascend,
 And wide in air robust arms extend,
 Nurse the new buds, admire the leaves unknown,
 And blushing bend with fruitage not its own.

From the Old Colony Memorial.

TO PLYMOUTH. October 31, 1822.

SIR—With many others I have read your communications upon the cock-chaffer with a great deal of interest. You are certainly very fortunate in your topic. Scarcely any one could be selected of more moment, or that ought to be more popular. The commendation which you have drawn from the Roxbury "Farmer" is no mean praise; and while his busy and potent pen is waking up the agricultural capacities of the people—I had almost said of his

country—their labors must not be shamefully left only to fatten this loathsome reptile, and heighten the evils of famine. In a cause like this, alarmed by the appalling view lately presented to us by many of our fields, it becomes every man to be a philosopher, which is only to observe correctly, and report faithfully.

To eat, or be eaten, is the order of things, as the world goes at present—and instead of going into a penurious calculation about the time inevitably devoted to self-defence in this state of perpetual annoyance—would it not be wiser to reflect, that we are all for *during the war* in this respect; that he is a good soldier, who cries and fights on, and receives a badge of honor, and is *commended in orders* at the close of the campaign.

Under these circumstances, 'tis impossible that motives to perseverance can be wanting, and patriotism, industry, taste and intelligence will work wonders any where.

In your last communication in the Memorial, I apprehend you were in an error, in stating that the cock-chaffer was then "just under the sod." But many of them had already descended, probably to avoid the winter. On the 19th inst. with several respectable farmers, and upon a spot where was *grass*, (for this grub does not eat every vegetable,) I made an excavation 18 inches deep, and shaving down the sides with a spade, I found *full grown* grubs in apparent good health, in all grades of descent throughout the whole distance. "Who forms the phalanx and who leads the way," may long be unknown; but, that they know when to set out and how far to go will hardly be called in question.

This fact is of importance, you will perceive, only in relation to the time for the ploughing, which you have well recommended, and may remove the doubts of the "Farmer" about the descent of this animal.

From my first attention to this subject in July, to the 26th inst. I have been constantly puzzled with finding *two* sizes, of what I consider the same worm in company. One size, which has uniformly appeared about the same, was not more than one eighth part of that of the full grown. This small sized grub was always at the root of the grass, as late as the 26th inst. though you supposed them to have gone down.

I conclude them both to be one species, because they have minutely the same external character. Through a pretty good glass they gave the same color, an equal number of horns—tentacula—incisions—spiracles and legs. *Four* of the latter on each side (instead of *three*.) as you have been the first to state. Indeed, so minute is the similitude, that two of the spiracles on two of the shoulders on each side, and at the same place are omitted.* But you say, there were "as many spots (spiracles) as incisions." I wish you would review this point. Correctness and not criticism is my object.

It seems to be admitted that the cock-chaffer has its *period*, of four or five years—if so, all

* In our last No. p. 118, plate I, is an engraving, copied from a figure of the cock-chaffer, given in Anderson's Recreations, vol. iii, p. 420. The resemblance is very accurate, excepting that in Doct. Anderson's figure, *three* spiracles or spots are omitted at the end of three of the shoulders, viz. the 6th, 11th and 13th, counting from the head of the insect, and including those in which the legs are inserted.—ED. N. E. F.

the grubs must be of one age, and nearly one size, and from a view of their nature, must pass their several metamorphoses exactly and forever in one and the same space and *period*. From this period, they could no more vary than the elephant from her two years gestation; and the progenitor, soon after depositing her eggs, is supposed to *perish*; though more agreeable to my theology, she only *dies*. Whence then these small grubs, too numerous to be anomalies? Are we then to believe an annual succession of cock-chaffer progenitors, and where it ends unknown; or resort to the doctrine of *equivocal generation*, a doctrine, which as yet, has more arguments than disciples.

I apprehend the public rightfully expect more from you upon this subject, and I intend to give you some account of several of each size of these grubs, which I have *fully committed* for trial in May.

COLONUS.

CURRANT WINE.

The samples of wine exhibited at Exeter were of white and red, by Mr. Samuel B. Stevens of Exeter; and of red, by Joseph Tilton Esq. of Exeter. The wine from the white currant, for body and flavor, was preferred; and the committee awarded to Mr. Stevens the premium. This wine had no distilled spirit mixed with it, and was made by the following receipts:

"To each gallon of clear juice was added two gallons of water, and to each gallon of the mixture was added three and a half pounds of white Havana sugar, and put immediately into a clean wine barrel; after it had done fermenting it was bunged tight."

The red wine of Mr. Stevens was made by the following receipt:

To each gallon of clear juice was added two gallons of water, and to each gallon of the mixture was added three and a half pounds of good brown sugar, and put into good barrels; after it had done fermenting, it was stopped tight. In February after it was made, one gallon of the best 11th proof Cogniac brandy was added to each barrel, and stirred up thoroughly."

Both these samples were of the vintage of 1821. Mr. Stevens has the last and present year, made from his garden five barrels of this wine. And those who need such inducement to commence the manufacture of it, should be informed that it is an article quick in the market for cash, at two dollars per gallon.

Haverhill Gazette.

An Agricultural Society has been organized in the County of Bristol. Samuel Crocker, Esq. President. An Address was delivered on the 6th inst. by Rev. Otis Thompson.

VEGETABLE PRODUCTIONS.

A Beet raised by Mr. E. N. Chaddock of Haver, Mass. weighing 21 pounds, and measuring 31 inches in circumference, was lately presented by him to the New England Museum. A beet which beat this was raised in the garden of Leonard Pratt, Esq. of Pembroke, which measures 32 inches in circumference, and weighed, when it was pulled, 22 pounds, and is mentioned as being in the Bookstore of Hill and Moore, Concord, N. H.—also in the same Bookstore, a radish 24 inches in circumference, raised in the county of Hillsborough.

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

BOSTON, SATURDAY, NOVEMBER 23, 1822.

No. 17.

FOR THE NEW ENGLAND FARMER.

ON THE CONSTRUCTION OF GATES.

If farmers were to calculate the time employed in taking down and putting up bars, compared with that of opening and shutting gates, they would, on principles of economy, substitute the latter for the former; at least wherever they have frequent occasion to pass. And there are few farmers, who could not make their own gates in the leisure of winter. A great proportion of gates are not so well constructed as they might be. The most common fault is the fixing of the brace to run from the top of the hind piece of the gate, sloping towards the fore end. Such gates always sag, and their fore ends scrape the ground. Reverse the position of the brace, and then, if the gate be well made of seasoned stuff, it will never sag. The following sketch of such a gate, with the notes subjoined, will render farther description unnecessary.

A FARMER.

FARM GATE.

The Har-tree $3\frac{1}{2}$ inches thick, and $4\frac{1}{2}$ or 5 inches wide.

The brace $2\frac{1}{2}$ inches wide and 2 inches thick.

The upper bar 7 inches wide.

The three next bars, 6 inches wide.

The lower bar 7 inches wide.

The gate may be hung with hinges, or hook and eyes, or with one hook and eye at top, and a gudgeon at the bottom of the har-tree, to turn in a hole, drilled into a hard stone, to be set close to the foot of the gate post. In the latter case the lower end of the har-tree should be rounded and receive a ring or narrow band to prevent its splitting.

The brace, besides the rivets, (one through each bar) should further be fastened to the bars by nails from the other side.

The brace, with its rivets and shoulders, renders it impossible for the upper bars to sag; and the two perpendicular pieces of board A. B. being riveted and nailed to the lower bars, effectually support them.

Full inch boards, even of white pine, will be strong enough for the bars; although hard wood or spruce would be preferable. If made of oak, inch boards would be amply sufficient.

The brace and har-tree should be of white oak, or hard pine.

ON THE USES OF THE COMMON NETTLE.

If we mistake not a patent has been granted in the United States for the exclusive right of making cloth of the nettle. Its uses, however, appear to have been well known in Europe for many years past. Dr. Anderson says (*Recrea-*

tions, vol. iii, p. 149:) "Some poor women, fishermen's wives near Leith, in Scotland, gathered some nettles, steeped them in water like flax, dressed it, and spun it into coarse yarn, of which a kind of canvas was made. As their husbands were in the practice of dredging oysters, and sending them to Glasgow in canvas bags, some bags for this purpose were made of the nettle canvas, which was found to answer the purpose much better than that made from hemp, as it was much longer before it rotted. It should be steeped and dressed in the same way as flax, but it requires to lie longer in water before it be fit to be dressed. It is harder to the touch than cloth made of hemp or flax."

Dr. Anderson, however, doubted whether it could be made profitable to cultivate this plant for use. He observed that "unless it be upon a very rich soil, it is a dwarfish plant; it would therefore be more difficult to obtain it in quantities, than either flax or hemp." Dr. Anderson thought, likewise, that the steeping of it would require a great degree of accuracy.

The medical virtues of the nettle are thus described in an English magazine: "In the form of a strong decoction or infusion taken in the quantity of a pound a day it is a most valuable strengthener of general or partial relaxation. In that of a weak decoction or infusion, it proves an admirable deobstruent in impurities of the blood, and in obstructions of the vessels. And in that of expressed juices, taken by spoonfuls as the exigency of the case requires, it is the most powerful styptic for internal bleedings known. Externally applied as a fomentation or poultice, it amazingly dissolves inflammation and resolves swellings. In the common sore throat, thus applied, and internally as a gargle, dependence may be safely put on this common plant."

It is said that the Russians obtain a green dye from the leaves, and a yellow dye from the roots of the nettle.

ACORN'S FOOD FOR SWINE.

The hogs that are fed upon the acorns that they gather in the woods of Germany and Poland, are reckoned to yield the finest bacon of any in Europe; and it is to this that most people ascribe the superior excellence of Westphalia hams. So says Dr. Anderson, and farmers who live in the neighborhood of oak forests might easily make experiments which would decide whether acorns are equal to Indian corn. (which we doubt) or what proportionate value they bear to Indian corn. In Virginia sweet apples and peaches, we have been told, are used for feeding swine.

CLEARING OF LANDS.

But little need be said on this subject; as he who has to undertake the clearing new lands will acquire more knowledge, from practice, of the best methods of subduing our heavy forests, than from any essay on the subject. He will find that the essential point is to put his shoulder to the wheel, and persevere undauntedly; and in a few years he will find his exertions

amply compensated by the pleasing scenes and profitable improvements which shall have been made around his dwelling.

When new Settlers first go into the woods, they have to spend much valuable time in hunting up their oxen and milch cows, which, for want of an enclosed pasture, have to run in the woods; and to remedy this, as soon as possible, we would propose the following:—About the first of June, take a suitable piece of ground, cut out the bushes, and all the small growth of timber which shall be under a certain size, say a foot over in the butt; pile all the brush round those trees which are left standing. In a dry time, in the month of August, set fire to them, and the fires will kill the trees left standing; then pile and burn what lies on the ground, which is soon done, and in due season harrow in a crop of wheat or rye, and in the following spring sow the ground over with herdgrass. The crop of wheat or rye, sown in this way, will be nearly as good as if the timber were all taken off; and the year following the ground will afford the requisite supply of pasture and hay. When the limbs of the standing trees begin to rot and fall off, cut the whole down and let them lie there; as the pasture will not be injured, but rather eventually benefitted, by the trees lying and rotting upon it. This method of killing trees by fire is, however, only recommended where they are such as cannot be killed by girdling; such as beech, maple, bass-wood, &c.

New Settlers, who will take this method of procuring a supply of pasture and hay, will find their account in two ways: It is turning the ground to immediate profit, with the least possible expense; and the surplus of hay and pasture will command an extra price; as those articles are always scarce, during the commencement of new settlements.—*Farmers' Assistant.*

Improvement in the Dasher of the Common Churn.

This dasher turns on the handle, by being fixed to it by a pivot. It consists merely of two cross pieces, suppose three inches square, put together, by being let into each other, in such a manner as to form four wings, which are cut beveling on each side, at an angle of forty-five degrees, so that they stand diagonally; the whole being very similar to the wings of the little wind-mills (so called) which are set up on poles, to be turned by the wind.

As this dasher goes down in the cream, it turns one way, on its pivot in the lower end of the handle, and as it comes up, it turns the other way; and this produces an agitation of the cream better calculated for producing the butter, than any method ever yet known. It is so efficacious in its operation, that the churning must be performed moderately, or the butter will come too soon, and be *swelled*, as it is technically called by some.

Mr. Fisher, the inventor of this dasher, obtained a premium in England for his discovery. The churning with this dasher is not attended with that splashing of the milk, so troublesome in the churn of the common dasher.—*Ibid.*

From the New-York Spectator of Nov. 13.

NEW-YORK CATTLE SHOW AND FAIR.

The task of making improvement on the earth, is much more delightful to an undebauched mind, than all the vanegory which can be acquired from raving; it by the most uninterrupted career of conquests."—WASHINGTON.

That the permanency of the prosperity of a nation, next to the liberality of its institutions, depends on its Agricultural and Commercial pursuits, is a position which we believe few will be disposed at this time of day to dispute. Altho' it may be said of Great Britain, that the glory she has acquired has been the fruit of her victories; yet if the cultivation of the soil, and her extensive manufactories had not yielded the means of prosecuting the wars in which she was engaged, she would have had no pre-eminence to boast of, when compared with other European states. It is from the soil, in fact, that every thing is derived which can be converted into a useful domestic purpose, or form the medium of our obtaining many of the necessities of life from other parts of the globe. Without agriculture, we should neither have bread to eat, nor clothes to put on. Without agriculture our commerce would sink into oblivion: and without agriculture, we would become as degenerate a race as the savages, who inhabited the woods and wilds, when this country was first visited by Europeans. A deep impression of the importance of this subject, gave birth to Agricultural Societies. These created funds, for the purpose of encouraging improvements, and bestowing rewards on merit, which it was not in the power of individuals to provide; and, in consequence of the judicious application of these funds, the most beneficial effects have resulted in all parts of the state: though we are not apprehensive that these institutions will be abandoned, we cannot shut our eyes to the apathy which has appeared in some counties, on a subject of such vital importance to the community. We trust, that nothing of the kind will ever be discovered amongst us; but, that those who really possess the means of contributing, will, instead of relaxing in the patriotic work, increase the support which they have been in use to afford; always keeping in mind, that "the task of making improvement on the earth, is much more delightful to an undebauched mind, than all the vanegory which can be acquired from raving; it by the most uninterrupted career of conquests."

We have thought the foregoing remarks not inappropriate by way of an introduction to a brief account of the New-York Cattle Show and Fair, for the exhibition and sale of live-stock, agricultural implements, and goods of domestic manufacture. The exhibition commenced, as our readers have already been informed, at Harlem, yesterday morning, and closed at one o'clock this day. The weather has been remarkably mild for the season, and notwithstanding the distance from town, the exhibition was better attended yesterday than we had anticipated. As we have given below the general Report of the Society, together with the pertinent address delivered this day at 12 o'clock, by Dr. MITCHELL, one of the Vice Presidents, we have but little room to detail the particulars that came under our own observation.

The exhibition of live stock, was on the whole highly creditable to this part of our state. We never witnessed a finer display of horses. Besides a great number of colts of blood, there

were upon the ground the famous horse Duroc, Old Hickory, and the beautiful Arabian, the Bagdad, imported last year by the Messrs. Barclays. The fat cattle were very fine, particularly one yoke from Westchester, and a lot brought upon the ground by Mr. Fink, of Orange county. Of cows there was but a poor display; and only two bulls that would be passable among judges of black cattle in England. Of working cattle, we saw nothing to compare with a yoke of two year old steers, brought from Poughkeepsie, and owned by Mr. John I. Copeman, of that place. There were some very fine sheep—native and merino; but no hogs deserving of notice.

The display of Goods of Domestic Manufacture, was extensive and exceedingly fine, both as it regards variety and quality. We cannot particularize the different articles, nor speak of their respective qualities. But there were broadcloths and cassimeres fit for any republican to wear; and if fit for republicans, they are certainly fit for any body else. The cotton goods from the Matteawan Manufactory, embracing shirtings, sheetings, and gingham of every variety, presented a highly gratifying spectacle. We noticed also several rolls of flannels of a superior quality, and some diaper table linen manufactured by Mr. David Auchinclole, of Hudson, which, as we have before said, is quite good enough for freemen.

There were no articles, perhaps, which attracted more attention than the imitation Leghorn hats. We have examined many fine hats of American and foreign manufacture; but we are free to say that there were three here presented to the public, which in every point of view, exceed any thing of the kind that has before fallen under our observation. The hat made by Miss Julia Harrison, of North East, Dutchess county, took the first premium; that of Miss Hedges, of Easthampton, (L. I.) the second; and that of Miss Babcock, of the same place, the third. There were several others, executed in a creditable manner, but only three were entitled to premiums.

Mr. Obadiah Parker, of Greenwich, exhibited some fine specimens of Upland and Sea Island Cotton, raised in his garden the late season; and there was another beautiful parcel, raised by Mr. M. Rogers, of Jericho, (L. I.) together with a pair of handsome cotton stockings, made from the same. But we will let the officers of the society speak for themselves.

The Society formed in procession at Dayo's Hotel, at 12 o'clock, and proceeded to the Church where an address was delivered by DR. SAMUEL L. MITCHELL.

(This address shall appear in our next.)

From the American Farmer.

RECIPT FOR PICKLING BEEF.

October, 1822.

DEAR SIR,—You have published a number of excellent receipts for curing beef, but as none of them contain the alkaline ingredient, on which the high fame of my grandmother's pickle has safely rested for the last half century, and which is believed to make it superior to any other, I send you the whole recipe, as worthy of preservation in your valuable journal, and of general adoption. Several writers have asserted that boiling the pickle will harden the meat; I must, from experience, dissent from this opinion.—Boiling and thus purifying the salt and water,

will certainly make a pickle that will bear warm weather better than pickle which has not been boiled—and I am convinced that the hardening of beef has been improperly ascribed to this practice. Whenever the hardening takes place, it is a consequence flowing from some other cause, and not justly attributable to the boiling.

Your Obedient Servant,
SWEET PICKLE.

MY GRANDMOTHER'S PICKLE.

The Beef, as soon as the butcher has finished dressing it, should be hung in a cool place, and become thoroughly cool to the marrow—then cut it up, and cleanse every piece, of blood, &c. in pure cold water; then let the pieces intended for hung beef, the briskets, &c. be lightly rubbed with blown salt, and laid in a pickle tub, that has been nicely cleansed; on these lay the rest, the thickest pieces first, till all, to be pickled, are snugly packed in. If the weather will permit, the beef will be tenderer and nicer by being suffered to hang two or three days in quarters, or to remain 24 hours in the pickle tub, before the pickle is poured on it.

Take 12 or 14 gallons of pure water (if not pure, make it so, by boiling well after the salt has been put in, and taking off the scum as it rises) and stir in good blown salt till it produces a brine, that will bear an egg well. The day before the salt and water are put together, put on a pot of pure water, into which put clean wood ashes, and boil till they produce a good ley, that feels a little slippery between the thumb and finger; put this ley away till the next day to settle; it will then look like pure water. Measure one gallon of this ley, taken up clear, and pour it into the salt and water, after that has been made to the proper strength, or if you boil put in the ley directly after boiling. Also put in at the same time four ounces of saltpetre beaten fine; and one pound of brown sugar, or a pint of molasses.—Stir the ingredients well together and let them stand till next day; then carefully scum off every thing, that has risen, and pour this pickle on the packed beef. The beef ought to have on it a barrel heading, or circular piece of wood to fit the size of the pickle tub, so as just to move up and down, and on this piece of wood put a flat, heavy, clean stone to keep all down snug in pack, and the pickle ought to cover the beef completely, and remain well above the top piece. In pouring the pickle on, do it carefully and steady, and reject any sediment that may appear at the bottom of the vessel, in which you have made it. In butchering and handling the meat, and in every part of the process, attention should be paid to perfect neatness and cleanliness.

The above quantity of pickle is sufficient for 500 weight of beef. If more beef is to be pickled at once, the quantity of pickle must be increased accordingly, observing to keep up the same proportion of all the ingredients.

N. B. The boiling the salt and water in every instance is the safest, especially if the pickle be made before the end of November, or after the middle of February, and is not much trouble, even though you may not have a boiling vessel that will hold more than half or a third of it at once.

Salem Alm-House.—One thousand bushels of Corn, besides an abundant supply of Potatoes

and other vegetables, have been raised at the Alms-House Farm the present season. The important improvements constantly making at this interesting establishment; the order and regularity with which every thing is conducted; and the neatness and comfort every where seen within its limits, reflect great honour on the present worthy Overseer, and entitle him to the lasting gratitude of the town.

Mr. Upton, whose mind is ever bent on some plan of usefulness, has suggested, (and we think the suggestion entitled to serious consideration) that a Dam might be built from the Alms-House wharf, across Collins' Cove, to the nearest point on the opposite side, which would afford suitable sites for Mills of various kinds, and be of great benefit to the town as well as individuals—it would also be a very convenient public way between Beverly, Bridge street, &c. and the lower parts of the town. The stone and gravel necessary for the construction of the Dam, are to be had in great abundance near the Alms-House, and by employing the men, teams and gondolas of the establishment, it might be executed at small expense.—*Essex Register.*

From the New York Statesman.

As you profess to devote a portion of your paper to the interest of agriculture, I take the liberty of communicating some facts relative to the turnip culture, which I have prosecuted this year to a greater extent than before.

My farm, on the Albany commons, is a sandy plain, and, so far as I can judge, very much resembles the celebrated turnip soil of Norfolk, in England. The idea, which is prevalent in many places, that the turnip requires a moist, rich, or very rich soil, is erroneous.—It is equally an error that they will not grow on old lands, provided they have a dry and sandy soil. In Norfolk there have been raised five crops on soils which were eight-ninths silex; and perhaps they do the best where the sand does not constitute less than 70 per cent of soil. I find I grow the best crop on the sides and tops of my most sandy hills; where in places more moist, and abounding in more vegetable matter, they are of diminished size, ill flavoured and stringy. Hence it has become a primary rule in my practice to sow this crop upon my lightest soils.

For table use, the later the turnip is grown the better. Those later sown, are more crisp, juicy, firm, and better flavoured, than those which are maturing during the heats of September. I therefore sow late; the common sorts from the 25th July to the 6th August, and the Swedes early in July.

As a crop for cattle food, I have yet but little experience, except with the ruta baga. Of the utility and profit of these I am fully satisfied.—They are raised as cheap as Indian corn. The average product is from 500 to 600 bushels. In a root cellar, or in piles of 100 bushels, buried up on the surface of the ground, they keep perfectly well, and are fed without being cut to neat cattle, with as little labor as any food.

I have raised turnips five years with uniform success, and always as a second crop.—You probably recollect the high reputation they obtained in the Albany market as a table vegetable. This year I have grown seven or eight acres, of different kinds, viz: the flat red top and green top, the Norfolk white, the Aberdeen yellow, the globe and ruta baga; and they all

prove excellent of their kind—the two first yielded at the rate of 760 bushels per acre.—The whole were raised on ground on which I had previously taken (the same year) clover, rye, wheat, flax and peas. Most of the ground had a light dressing of manure, which was ploughed under, and the seed sown broadcast, and harrowed in. They were thinned and weeded with the hoe once only.

I contemplate sending a few hundred bushels to your market in a day or two, when I beg you will do me the favor to call at the boat and view them. I think they are not surpassed for beauty and goodness by any which I ever saw.

Your obedient servant,

JESSE BUEL.

BREED OF HORSES.

The fine exhibitions of this animal at the late Cattle Show in this county, have led to much conversation, and excited a laudable spirit of emulation; and it is hoped a subject of so much importance to the community will continue to attract public attention, until the state is stocked with a new race of horses. Although the first premium was awarded to the celebrated *Duroc*, of Dutchess county, yet the beautiful Arabian *Bagdad*, imported and owned by Mr. Barclay, of this city, is said, by good judges, to be little if any inferior to his elder and successful rival; and the most sanguine hopes are entertained, that the stock from *Bagdad* will contribute much to the improvement of our breed of horses. As the two competitors are kept in different parts of the state, the interests of their respective owners can in no way interfere.—*ibid.*

From the Old Colony Memorial.

That the following may receive the notice which it deserves, we take the liberty of stating, that it is received from the Rev. Mr. Allen, of Pembroke, who has used it on the sides and roof of all of his buildings, except the house in which he resides. At a very little distance, the paint on the latter cannot be distinguished from this cheap and ornamental mixture. Beside the neat appearance it gives, it may be recommended by the arguments of economy, as protecting the wood from the vicissitudes of weather, and of precaution, in guarding against fire. The latter should be an argument of great weight in this town. We can in no better way express our gratitude for the signal favour of Providence, in saving us from the ravages of this destructive element, than in guarding in every convenient and practicable way, against the mischief it may occasion.

This cement is designed as a paint for the roofs of houses. It answers all the purposes of common paint, and also protects the roof from fire. Those who are now erecting new houses, or are about to paint the roofs of old buildings, would do well to try it. The expense of painting a roof in this way would be much less than the common method.—The cement becomes very hard and glossy, and is said to be more durable than the best kind of paint. The following is a receipt for making it:—Take as much lime as usual in making a pail full of white-wash; let it be sifted in the pail nearly full of water; in this put two pounds and a half of brown sugar, and three pounds of fine salt—mix them well together, and the cement is composed.

A little lamp-black, yellow ochre, or other colouring commodity, may be intermixed, to change the colour of the cement, to please the fancy of those who use it.

From the Northampton Gazette.

Saxon Sheep.—Our enterprising townsmen, Isaac C. Bates, Esq. and Col. James Shepherd, have recently imported two Saxon bucks, which have arrived in town. They were purchased in Saxony for these gentlemen more than a year since, and selected by a good judge, as the excellence of the animals evinces. It is well known that Saxon wool commands a higher price in the English market than Spanish. It is the material of which the superfine wools of England cloths are made. The growth of it, therefore, in this country, is important to the agricultural and manufacturing interests. These bucks are of the merino race of sheep, but improved. They are remarkable for the fineness, delicate softness, and singular uniformity of their fleeces, and are an acquisition to the country, for which the proprietors are entitled to a meed of thanks.

Sheep.—In the Report of the Committee on Sheep at the Worcester Cattle Show, it is stated that England and Wales possess 26 millions of Sheep, the annual produce of whose wool is 27 millions of dollars. England imports from Spain about one fifteenth of the whole quantity of wool which she manufactures. Three fourths of the wool wrought by the woollen manufactories of the United States is the product of foreign soil.—*ibid.*

Extraordinary Product.—Mr. Edwin Lathrop, of Hawley, raised the past season one hundred and eighty summer squashes from one seed.—*ibid.*

A new Method of heading Cabbage in the Winter.

Last fall, at the usual time of taking in Cabbages, I had a number well grown, but had no appearance of a head. I dug a trench on the southern declivity of a hill, about 18 inches wide, and 20 or 22 inches deep, and took 36 cabbages of the above description, and set them out in the bottom of the trench, in their natural position, with the roots well covered with sand: I then filled the trench with straw on each side of the cabbages, and laid straw over the tops of them, to prevent the sand from getting in; then placed a rail over the middle of the trench, to prevent any pressure on the cabbages, and then completed the work by throwing on more straw, and forming a ridge of sand over the whole, to keep out frost and water. In the latter part of March, I opened the trench and took out the cabbages, and found each one with a common sized head, white, solid, and well tasted.—*anon.*

Easy method of breaking Glass in any required direction.—Dip a piece of worsted thread in spirits of turpentine, wrap it round the glass in the direction that you require it to be broken, and then set fire to the thread, or apply a red hot wire round the glass, and it does not immediately crack, throw cold water on it while the wire remains hot. By this means glass that is broken may often be fashioned, and rendered useful for a variety of purposes.—*Eng. pap.*

From the National *Ægis*.

MINERALOGICAL.....No. II.

To obtain a knowledge of the properties of those bodies which are found on the earth, or beneath its surface, which are destitute of an organic structure; to distinguish and bestow names upon them, and to give to them a suitable description and an orderly arrangement, are the objects of the science of Mineralogy. Hence results its connexion with Agriculture. The Farmer employs many substances, as manures, which belong to this comprehensive division of the family of nature. The soil which he tills, is composed of various constituents and filled with numerous fragments, which are properly to be considered as minerals. To become acquainted with the names which have been bestowed on these, without studying the qualities they possess, is a trilling, fitted only for the amusement of the indolent. To discover that the most precious of gems, is called the Diamond, and that one of the most valuable of manures, is denominated Marle, is making but a small advance in improvement. The practical man will consider how the value of the former may be enhanced and its beauty increased by its susceptibility of a polish, and will reflect on the economical application of the latter, to the renovation of lands exhausted by repeated crops, or its power of increasing the fertility of those which are still productive.

Whether that mass of mineral ingredients combined with various decomposed animal and vegetable matter, spread over the surface and called soil, serves only as a support for plants and a medium by which nourishment is transmitted to them, or whether it prepares and furnishes their food, in either view, its constitution is equally deserving of attention. It has been proved by experiment that particles held in solution pass unchanged into the roots of plants. Vegetables have been made to grow in solutions of salts, and examination has shown that they were tinged with the peculiar colors of the liquids in which they were immersed, and analysis detected that the salts themselves had been absorbed. This has been the case when the mixtures employed were of the most poisonous and deleterious nature. If plants then, have not *discernment enough* to select that food which is proper for their support and reject that which is destructive to their existence, it is the more necessary that the cultivator should remove from them the means of committing a kind of suicide. The noxious elements, which render the soils in which they abound unfit for crops, are few. They are generally such as may be neutralized, or converted into agents of fertility by appropriate applications and dressings.

It is not unusual to find the surface of standing waters in meadows, where the earth is apparently rich, mantled with a floating incrustation of various hues. Such an appearance is an indication of the presence of Iron combined with Sulphur, in the proportions which form the sulphate of that metal, well known by the more familiar name of Copperas. The same substance is detected by its color, or by its taste on higher lands. Wherever it exists it is an unfailing cause of sterility. By the application of Carbonate of Lime the action of this pernicious acid is not only neutralized, but the sulphuric acid, leaving its former combination, unites with the lime forming the sulphate of Lime or Gyp-

sum. In this manner qualities which are injurious to vegetation, are converted into others which are favorable to it. Similar examples, would all demonstrate the utility of that science which furnishes information on the constituents of soils, and provides us with the means of supplying their defects, correcting their noxious qualities, and adding to their productiveness.

A detail of the several processes, which are employed for the analysis of soils and discovering the minerals of which they are composed would exceed our assigned limits. Nor is such an explanation now necessary. It has been already given by Professor Davy, a man in whose foot-steps no successor may follow and find any thing remaining for improvement. The object of our remarks is merely to recommend this department to *practical* men. It is sufficient to say that by following the clear and perspicuous directions which he has laid down, results are arrived at with the greatest ease. No long previous acquaintance with Chemistry is necessary. A few simple principles comprehend all the secrets of this science in its connection with agriculture. None need be deterred from pursuing it by the apprehension of encountering insuperable difficulties. The little study which it may require, the small portion of time which it may demand, will be abundantly remunerated in the increase of knowledge, in the amelioration of the earth, and in the improvement of its harvests.

A FARMER.

From the National (Vermont) Standard.

WHEAT

Is one of the most valuable productions of our soil, and the only one on which we can generally safely calculate for exportation at a profit. In a very considerable portion of this state, so large a proportion of our lands have already been cleared, that very little of this grain will, in future, be raised upon newly cleared lands. Most of what shall be hereafter raised, must be raised on lands which have been sometime under cultivation. On such lands, this valuable grain is many times liable to injury from the *blast*. A certain remedy for this injury is very desirable. In order to stimulate our farmers to an inquiry into the cause which tend to produce this injury, and to exert themselves to search out a remedy, we present them with the following extract from Dr. Dwight's travels in New-England, recently published, which contains his theory on the subject of the blast in wheat. Dr. Dwight, in his various tours through the New-England States visited almost every town, and became intimately acquainted with the different modes of husbandry pursued in each. From his known talents, information and particular attention to those subjects which he considered of public interest, of which agriculture was one of the most prominent, any observations from his pen, on this subject, will, unquestionably, be perused with interest and attention, by all who duly estimate the importance of this crop, not only as it respects our farmers individually, but the interest of the State generally. If his theory is correct, our limestone ledges, will, with little labor, furnish us abundantly with one of the remedies which he prescribes, and become a much greater source of profit than they have heretofore been.

The reason why the lands in New-England, which formerly yielded wheat surely and plen-

tfully, suffer at the present time such injuries from the blast, as in a great measure to discourage farmers from attempting to cultivate it, has been anxiously and extensively sought for, but not, it is believed, satisfactorily discovered.—From my own observation, and inquiries, I have been induced to attribute this evil to the agency of animal manure. This subject has been already mentioned in my observations on the county of Worcester: it shall now be resumed.

The manner in which *Wheat* is generally blasted in New-England, appears to me very evidently to be this. During the months of June and July, when the kernels of wheat in the different climates of New-England are in the milk, the vegetation is far more rapid than in most countries of Europe. Whenever the season at this period is both moist and hot, the rapidity becomes extreme. The vegetable juice, ascending then in too great quantities, and with a new celerity, wears with difficulty through the vessels of the stalk, regularly lessening towards the neck, and at that time so tender as to be easily ruptured, bursts them in various places; particularly at the neck: and flows out upon the surface of the stem. When it first exudes, it is very sweet to the taste; and has hence been commonly supposed to be the residue of a particular kind of dew, called by the farmers *honey dew*. Had any farmer recollected, what he cannot fail to find when he finds a honey dew, that it never appears on any thing beside living vegetable, and that, if it were a dew, it must be found equally on every other substance exposed to the atmosphere; he would certainly have determined, that it was merely the sweet juice of the vegetable itself. When this juice has pervaded the stalk, it soon becomes sour in the sunbeams; then so acid, as to corrode the stalk; and finally a rust, (as it is commonly called,) of a brown hue, and an offensive smell.

Animal manure, beyond any other accelerates vegetation. Wheat nurtured by this manure, grows with so much rapidity, and with so tender a stalk, that in the agricultural language of this country, it *lodges* not unfrequently, (i. e. it falls under the pressure of wind or rain) by its own weight; and never recovers its original position. This dangerous process is peculiarly advanced by the use of this manure; and the rapidity of vegetation otherwise too great, is by this substance rendered still greater. Hence all fields, when this manure is employed, are peculiarly exposed to blast. For a few years after lands are dressed with it the evil is so evident to the eye of common observation, as to be not unfrequently believed to exist by some farmers, and suspected by others. Were every season hot and wet, during this period, it would, I doubt not, have long since been generally realized and acknowledged. But as in some seasons these months are cool and dry; and those fields which have been dressed with this manure, then yield wheat successfully; and as in the most unfavorable seasons, lands dressed in a different manure, are also subjected to the blast; the question has hitherto failed of any answer, which has been generally satisfactory.

The reasons, which have induced me to adopt the opinion here alleged, are principally the following:

1. All the lands in this country, which were not too wet originally yielded wheat, easily,

urely, and so far as they were rich, abundantly. The inhabitants of North-Hampton for many years paid their public tax in wheat; and this wheat grew on the very lands, where for a long period it has been supposed to be so uncertain in object of culture, as to be scarcely worth the attempt, i. e. on *Intervales*.

2. New lands yield wheat perfectly well in most parts of this country at the present time. Some farmers believe, that there is such a change wrought by time, either in the climate or in the soil, independently of the proper effects of culture, that the blast is to be attributed to this change. Although this is a mere supposition, supported by no evidence, it has still had its weight. But it is entirely refuted by the fact, mentioned under this head. Lands in the same circumstances yield wheat as abundantly at the present time, as at any former period. It deserves to be remembered, that all the *Intervales* along the Connecticut have furnished some crops of this grain for a considerable time after they first began to be cultivated.

3. Lands dressed with ashes, now furnish fine crops of wheat, which is rarely or never blasted. The only reason why the crops on new lands are so safe from the blast, is, that they are covered with vegetable mould; another name for vegetable manure; and so long as the efficacy of this manure lasts, are dressed with no other. It is the universal tendency of this mould to produce great crops; but it produces them by a gradual and moderate vegetation. Ashes, which are the same manure in another form, produce the same effect in exactly the same manner. Accordingly, although the crop of wheat, yielded by grounds dressed with ashes, is abundant; yet the stalk is firm, and strong; much stronger but much shorter than that produced by animal manure, and equally safe from edging, and blasting, as that which grows on vegetable mould.

It ought to be observed, that in grounds, where the vegetable mould is very deep and abundant, wheat grows so rapidly as to be universally blasted. That this effect is solely derived from the redundancy of this manure is certain, because the same lands after the cultivation of a few years, yield wheat perfectly well.

4. In various instances, which have fallen within my knowledge, wheat, sown after clover, has been perfectly free from any injury by the blast; and that on *Intervales*, and other lands most liable to this injury. Here vegetable manure has been employed in another form; yet the same effect has been produced.

5. Lands, dressed with gypsum, have been equally favorable to wheat. This good effect has, however, been commonly produced through the medium of clover; the gypsum having been first employed for the production of this plant, and the wheat having been sown after the clover had been ploughed in.

6. Fields, manured with the white fish, have yielded wheat, universally, in great abundance, and with almost absolute certainty. This is indeed animal manure also; but very different from that, which I have introduced by this phrase above; viz. that of the stable and barnyard. The white fish is a species of herring, very fat and oily, and remarkably favorable to vegetation of every kind, which is the object either of agriculture, or horticulture. I have mentioned this fact, to show, that the evil com-

plained of, has its origin neither in the soil, nor in the climate; but in the particular mode of cultivation, which I have mentioned as its proper cause.

7. The lands in Pennsylvania, which yield plentiful crops of wheat, are regularly dressed with lime, or gypsum; and neither here nor in those old settlements in the State of New-York where this grain is least exposed to the blast, are cattle very numerous. Of course the kind of manure, which I suppose to be noxious to this plant, cannot abound in these countries. I am informed also, that, when this manure is used, it is generally mixed with other substances in a *compost*; and converted, either partly, or wholly, into mould, before it is employed as a dressing. It ought also to be observed, that a great part of the wheat lands in these countries are clay; and that the process of vegetation may be therefore materially different from that, which exists in New-England, where the soil is principally loam with a mixture of gravel. It is however said, that in Pennsylvania their crops fail, when they are unable to dress the lands in lime, or gypsum.* It is also said that the lands along the Mohawk River, which have heretofore yielded wheat with great certainty, as well as luxuriance, are gradually becoming less and less fitted for this kind of culture.

I have been informed that at Newbury they have lately adopted a new kind of husbandry, by means of which the crops of wheat are no less sure, and prosperous, than they were formerly. What this mode is, I have not, however, been able to learn.

In my own belief, animal manure produces this noxious effect long after it has ceased to enrich the soil. Although its influence has in this case become small; yet, so far as it extends, it is mischievous; and may, at the dangerous period above mentioned, accelerate a growth, at least sufficiently rapid otherwise, so as to produce the evil in question. Thus I consider grounds, long devoted to pasturage, as being injurious to the culture of wheat as really, though in a less degree, as those which are manured from the stable in form.

It ought, however, to be observed, that since the Hessian fly has rendered it impossible to cultivate what is here called *white bull wheat*, we have lost the species best fitted for the soil and climate of New England, as well as that which furnishes the best bread. All the substitutes for this wheat have yielded inferior crops; have been more exposed to the blast; have been more injured by the frost; have weighed less; and been of an inferior quality.

Should these observations be allowed to merit the attention of farmers in this country, it would certainly be worth an experiment to see how far the use of vegetable and mineral manures, would remedy this very serious evil.—Were lands, intended for the culture of wheat, to be employed for this purpose during a con-

* This remark, and indeed the whole tenor of the article has a tendency to confirm what we have observed in No. 12, pp. 91, 92, of the N. E. Farmer, relative to the necessity of lime, in some of its combinations, to insure the production of wheat. Fish makes a useful manure for wheat, because it contains, together with other food for plants, *phosphate of lime*, in greater quantities than most animal substances.

Ed. N. E. Farmer.

siderable period; were clover or other vegetable substances, or, where they can be obtained, mineral manures, to be alone employed as the means of enriching the soil, I am persuaded my countrymen would again see their crops of this grain not less sure, less abundant, nor less general, than they were in former times."

From the Farmers' Weekly Messenger.

SIGNS OF A GOOD FARMER.

His corn land is ploughed in the fall—His bull is from two to five years old and he works him. He seldom lets his work drive him. Has a cooking stove with plenty of pipe to it. The wood lots he possesses are fenced. His sled is housed in summer, and his cart, ploughs and wheelbarrow, winter and summer when not in use; has as many yoke of good oxen as he has horses—Does not feed his hogs with whole grain—Lights may be seen in his house often before break of day in winter—His hog-pen is boarded inside and out—Has plenty of weeds and mud in his yard in the fall—All his manure is carried out from his buildings and barn yard twice in the year, and chip dung once a year—His cattle are almost all tied up in the winter—He begins to find out that manure put on land in a green state is the most profitable—Raises three times as many turnips and potatoes for his stock as he does for his family—Has a good ladder raised against the roof of his house—Has more lamps in his house than candlesticks—Has a house on purpose to keep his ashes in and an iron or tin vessel to take them up—He has a large barn and a small house—seldom has more pigs than cows—adjoining his hog-pen he has a hole to put weeds and sods, and makes three loads of best manure from every old hog and two from every pig. A good farmer in this country begins to find out that steaming vegetables can be done at one third the expense of boiling, and that the Ruta Baga turnip is a thing worth thinking of—he fences before he ploughs and manures before he sows—He deals more for cash than on credit.

HABITS OF CATTLE WITH RESPECT TO FOOD.

It has been observed by some American writer upon Agriculture, that American Cattle were not so fond of turnips, ruta бага, and some other plants not generally cultivated for feeding stock in this country, as it should seem that English cattle were. This apparent squeamishness of our native breed of cattle may be accounted for by any one who will make a proper application of the following passage from Anderson's Essays on Agriculture, vol. ii, p. 6.

"Although it may be presumed, that in general, instinct points out to animals the plants that are hurtful to them or the reverse; yet experience sufficiently shows that this cannot be relied on as an invariable guide—among domestic animals at least; which, by having little freedom of choice from their infancy, have their taste in all probability depraved, as well as our own. I have seen oxen that on no account could be brought to eat turnips; and there are very few put upon them, who do not eat them at first with some degree of reluctance, if they have not been sometimes accustomed to taste them before; yet it is very well known, that few kinds of food are more nour-

ishing and palatable to cattle, after they have been accustomed to it."

The following from the *Farmer's Assistant*, will show that instinct is not an infallible guide for horses, as respects the food which is best adapted to their nourishment.

"Pumpkins are excellent for fattening horses. They, however, do not relish them at first; and therefore must be kept from feeding, till they are hungry, before the pumpkins are offered to them; and let a little salt be first sprinkled on this food, when they will soon grow fond of it and eat it readily, without salt."

If "hunger makes good sauce for horses," no doubt it would answer for cattle, and might make the latter relish turnips as well as the former pumpkins. But cattle or horses fed upon pumpkins, turnips, or any such succulent food, or upon green clover, &c. should be salted more liberally than those, which are confined to hay or other dry food.

From the American Farmer.

Improvement of Neat Cattle—Pedigrees of Imported Animals, &c. &c.

We have witnessed with peculiar pleasure, the persevering and praiseworthy zeal which Col. Jno. H. Powell, of Philadelphia, continues to manifest for improvement of our breeds of Neat Cattle; as well by judicious selections from our native stock, as by the importation of chosen animals from England.

In No. 6, of this Vol. page 45, we published a list of animals, which he had collected chiefly from the Eastern States, for the purpose of exhibiting them in Pennsylvania, and distributing them at cost, amongst the Farmers of his native and other states. And in No. 16, pages 122—3, our readers will have noticed an official account of the exhibition, made by the same gentleman, of some of those animals, and of other native and imported stock, before the Philadelphia Agricultural Society, for nearly all of which premiums were awarded to Col. Powell, that were instantly and generously relinquished by him, for the benefit of the Society.

In the same number, the effects of this gentleman's judicious and spirited efforts, to advance the interests of his neighbours, may be traced through the list of premiums obtained by them for superior young Neat Cattle, that partook of the blood of the improved breed, which he had brought to their notice and placed at their service.

We rejoice to learn that Col. Powell has ordered some more animals from England, and hope that he may realize his loftiest expectations from the enterprise. From Mr. Wetherill, the breeder of Mr. Williams' celebrated Bull "Denton," and from Mr. Champion, the breeder of Colonel Lloyd's beautiful and promising Bull "Champion," he may justly expect to receive some of the most improved cattle of Great Britain. And no where could such Stock be better placed than within the reach of Pennsylvania Farmers; who, like their judicious fellow citizens of Massachusetts, will gladly embrace every opportunity to improve the breeds of their Neat Cattle.

And that all may hereafter avail themselves of the offspring of such animals as prove to be the best of their kind, we have proposed to record the pedigrees of imported and celebrated

stock, which we will thankfully receive from owners, or others who possess such information, and carefully register it in our columns. We are indebted to Col. Powell for the following pedigrees of two very valuable imported animals, and two others of imported breeds.

PEDIGREES.

FLOA. (an imported thorough bred improved Durham Short Horn Cow) was by Sampson—dam was Betty—grandam Old Betty, who came from the neighbourhood of Darlington, Durham County, England—Sampson was by son of Ossian—Ossian was by Favorite—Sampson's dam was by Comet—Comet was by Favourite.

ROSE is also a thorough bred improved Durham Short Horn Cow, and was purchased near Darlington.

LOTHARIO, a bull of 7 months, was from Rose, by George—George was by Phenomenon—dam by Favorite—grandam by H. Allison's Gray—great grandam by T. Charge's Old Gray—Phenomenon was by Favorite, from Elvira, bred by Sir H. Vane Tempest—Elvira was by Old Phenomenon, from Princess, both bred by Robert Collings—Princess was by Old Favourite.

CORA, was by Mr. Williams' bull Denton, from Julia—Julia was by Denton, from Mr. Williams' imported cow Devon—Denton was by Old Denton—dam by Baronet—grandam by Cripple—great grand dam by Irishman—Old Denton was by Comet.

THE FARMER.

BOSTON:—SATURDAY, NOV. 23, 1822.

ON SAVING AND MAKING THE MOST OF MANURE.

(Continued from page 111.)

It has generally been taken for granted, by those who have considered themselves as adepts in the science of agriculture, that the great store-house of nature contained, in some corner of the apartment, a very valuable substance, called *food for plants*. This they supposed to be the essence of all manure, and the only thing needful, in order to raise, on any soil to which it might be applied, as great crops as could possibly find room for their tops and footstalks. They therefore set about exploring and experimenting, rummaging and ravaging the animal, vegetable and mineral kingdoms in search of this magical substance; this farmer's philosopher's stone, which would metamorphose a desert into a flower garden as it were by the wand of a necromancer. At length certain philosophers verily believed, and told the world their opinions, that they had found the identical *pabulum of vegetation*, as they called it, and that agriculturists had nothing to do but to manure their fields with the said pabulum in order to procure the best and most profitable of all possible products. But, unfortunately, it so happened that no two, or at least no half dozen of these learned and ingenious system-makers could agree upon the nature and constituent parts of this appropriate diet for vegetables; and of course the said vegetables were obliged to pick up a living as they could, while their philosophic caterers were preparing moses precisely adapted to their appetites and constitutions.

DuRoi and Tull were of opinion that the *earth* in which plants grew, furnished their principal food. That in order to enable their little mouths, (which were placed in their roots) to imbibe their nourishment, the soil must be ploughed and harrowed till you had

almost demonstrated the infinite divisibility of matter by actual experiment. If the food of vegetables was reduced to an impalpable powder, as much finer than snuff as snuff is finer than grape shot, they imagined it would be more easily swallowed and digested, than if it remained all kneaded together, or its particles were congregated in coarse lumps, which plants could neither carve into particles of a proper size for deglutition nor take in and decompose or digest without division.

Van Helmont and many other men, who have been famous in the annals of philosophy, were confident that *water* is the one thing needful for the growth of every species of vegetation, and that the soil, in which plants are fixed is no otherwise useful than as it serves to sustain them in an upright position and to convey water to their roots in such quantity as may be adequate to their wants. Very many able writers have adopted this theory, and it would seem that even at this day it is not without its advocates.*

* Lord Kaimes was of this belief which he fortifies by the authority of Lord Bacon, who, he observes, "gave his opinion, that for nourishing vegetables, water was almost all in all; and that the earth serves but to keep the plant upright, and preserve it from too much heat, or too much cold."

Gentleman Farmer, p. 363.

More modern writers have also given some countenance to this theory, as may be learned from the following note from Parkes' Chemical Catechism, p. 453, 10th edition.

"That vegetables will grow in woollen cloth, moss, and in other insoluble media, besides soils, provided they be supplied with water, has been repeatedly shown since the days of Van Helmont and Boyle; but the experiments of a modern author, from their apparent correctness, seem more highly interesting and conclusive. "Seeds of various plants were sown in pure river sand, in litharge, in flowers of sulphur, and even among metal, or common leaden shot; and in every instance nothing employed for their nourishment but *distilled water*. The plants thrived, and passed through all the usual gradations of growth to perfect maturity. The author then proceeded to gather the entire produce, the roots, stems, leaves, pods, seeds, &c. These were accurately weighed, dried, and again weighed, then submitted to distillation, incineration, lixiviation, and the other ordinary means used in a careful analysis.—Thus he obtained from these vegetables all the materials peculiar to each individual species, precisely as if it had been cultivated in a natural soil,—viz. the various earths, the alkalies, acids, metals, carbon, sulphur, phosphorus, nitrogen, &c. He concludes this very important paper nearly in these extraordinary words: "*Oxygen and hydrogen*, with the assistance of solar light, appear to be the only elementary substances employed in the constitution of the whole universe; and Nature, in her simple progress, works the most infinitely diversified effects by the slightest modifications in the means she employs." See "*Recherches sur la Force assimilatrice dans les Végétaux*," par M. Henri Braconnot, *Annales de Chimie*, Fev. et Mars, 1803.

Professor Leslie has made many experiments on a variety of earths and stones by means of his improved hygrometers, the results of which are highly deserving the attention of all practical agriculturists. From these researches he has been induced to think it probable, that the fertility of soils depends chiefly on their disposition to imbibe moisture. See his *Short Account of Experiments and Instruments depending on the Relations of Air, Heat, and Moisture*, octavo, pages 94—102."

Notwithstanding plants can be made to grow in pure water, that circumstance does not prove that water is *exclusively* food for vegetables, any more than their growing in air (as some vegetables will) would prove that element to be their appropriate food. It might as well be said that the possibility of fattening an ox on potatoes is an incontrovertible argument that potatoes are the principal and almost the exclusive food of animals. Although plants may have power to change

Dr. A. Hunter, the author and compiler of several volumes of *Geological Essays*, many of which contain very useful observations, and facts, which are the heralds of much agricultural science, thought that he too had discovered the genuine food of plants. "I lay it down," he observed, as a fundamental maxim, that all plants receive their principal nourishment, from oily and mucilaginous particles, incorporated with water, by means of an alkaline salt, or absorbent earth. Till oil is made miscible, it is unable to enter the radical vessels of vegetables, and on that account Providence has bountifully supplied all natural soils with chalky or other absorbent particles." Experiment, however, the only infallible touchstone of theory, at length convinced Dr. Hunter that the cheapest oil was a very lean, but not very efficient article in a manure or compost heap; and oil, considered as a pabulum of vegetation, was held in no higher estimation than the substances which it had superseded.

The atmosphere had the honor of being next promoted to the office of purveyor of plants, and victualler of vegetation. The whole vegetable kingdom, from the cedar of Lebanon to the moss upon the wall, from the oak of the forest to the parasitical plant, which, according to Sir Joseph Banks, buttens upon the stalk of wheat, and causes mildew, was fed on air like a can-lion; and manure derived all its utility from its attraction for the atmospherical pabulum, or panacea. That air does contain food for plants is evident from the circumstance that the house-leek and various sorts of mosses will increase in weight without the aid of water or earth. But there are some other substances which appear to possess it in greater quantities, and better prepared for the purposes of vegetation. Thus a plant, which is partly withered in the air, may be revived by being sprinkled with water, and water lightly impregnated with muriate of soda, [common

oxygen and hydrogen into "the various earths, the alkalis, acids, metals, carbon, sulphur, phosphorus, nitrogen," &c. it would probably be more convenient for said vegetables to be fed with food, which contains such products as enter into their composition and make a part of their substance, ready manufactured, than to be under the necessity of manufacturing the whole from oxygen and hydrogen, which M. Braconnot appears to believe are the primitive particles, or raw materials from which the universe was constructed.

Some remarks by Mr. Cooper, Editor of the last American edition of Dr. Willch's *Domestic Encyclopedia*, would appear to strengthen the conclusion of M. Braconnot.

"In the case of the decomposition of animal substances, whether in the dry, or the moist way, no acid appears: we get azote, a fetid animal oil, swimming at the top of a volatile alkaline liquor, and sometimes concrete volatile alkali, or carbonate of ammonia comes over. The retort contains an animal charcoal, consisting of azote, carbon loosely combined, the base of the prussic acid, and if bones be used, phosphate of lime."

"In this case, the azote, the lime, and the phosphorus, seem to be new combinations, the result of animal organization, modifying chemical affinity. There are many districts of Pennsylvania, perhaps the best pasture land in it, that do not contain a particle of lime-stone. Such for instance as a great part of the county of Luzerne, and the beech country comprehended between the north-east branch of Susquehanna, the N. York state line and the Delaware. There is no finer grass country; but lime-stone is rare throughout the greatest part of this space. A calf bred up there, will have bones, that is phosphate of lime; his flesh will yield azote, either by distillation, or by the nitric acid: Where does he get it? The soil contains none; the grass on which he feeds contains none, but the ox is chiefly composed of azote and phosphate of lime."

salt] and perhaps some other saline substances, will preserve vegetables from drooping longer than pure distilled water. At any rate, it is pretty evident that the atmosphere is not a very rich food for vegetables, because it robs a manure heap of its fertilizing qualities, although it communicates such qualities to a hungry loam. It is like a pint of water about half saturated with common salt, which by mixture will make a quart perfectly fresh water somewhat brackish; or if the quart of water was fully saturated with salt, somewhat more fresh. In other words, the atmosphere causes very rich land to become poorer, and very poor land to become richer, and can with no more propriety be said to constitute the food of plants, than earth can be said to constitute the food of mankind, because some savages in South America are said to support nature, in times of scarcity, from a sort of fat loam or mould which they dig up and swallow.

While philosophers were thus floundering on from one deep abyss of error to another still deeper, Chemistry came forward, and proffered its lamp to guide their feet. By analysing vegetables, chemists professed to ascertain, precisely, what kind of matter entered into their composition, or, (to express the same thing in more familiar terms) what sort of stuff they were made of. The simple substances which they found in plants are principally oxygen, [vital air] hydrogen, [inflammable air] and carbon [coaly matter.] Some others are found in smaller quantities, such as phosphorus, lime, silica, &c. &c. and seem to be rather accidental additions than substances which are indispensable to their existence.* These few simple elements, by being variously compounded and modified, produce gum or mucilage, starch, sugar, albumen, gluten, gum elastic, extract, tannin, indigo, narcotic principle, bitter principle, wax, resin, fixed oil, volatile oil, woody fibre acids, alkalis, &c. &c. When these premises were once established, and it was discovered that nearly all the substance of all plants was hydrogen, oxygen, and carbon, it followed, as Sir Humphrey Davy has expressed it, that "no one principle affords the pabulum of vegetable life; it is neither charcoal, [coaly matter] nor hydrogen, [inflammable air] nor azote, [the elastic substance which forms a great part of the atmosphere and which is incapable of supporting combustion] nor oxygen, [vital air] alone; but all of them together in various states, and various combinations."†

We believe that this theory of Sir Humphrey Davy is the most correct of any which has been advanced, and hope, in a future number, to deduce from his principles some results which may prove of practical utility. (TO BE CONTINUED.)

* It is thought, however, that lime and silica are indispensably requisite for the existence of some plants, in which they are always found by analysis.

† See *Agricultural Chemistry*, lecture 1, p. 18, Baltimore edition.

Col. Powell's Improvements in the Breeding of Cattle.

We have republished in this day's paper, p. 134, an article from the *American Farmer*, headed "Improvement of Neat Cattle," with much satisfaction; and are happy in an opportunity of expressing our sense of the merit which attaches to such exertions of wealth and talent to become useful as well as eminent. Colonel Powell is well known in Massachusetts as a liberal and enlightened Agriculturist, and his efforts to promote the interests of those who cultivate the soil will be as highly appreciated in New England as in Pennsylvania.

Mr. Fick, of New York, selected from an half acre of cabbages, 7 heads, which weighed 134 pounds.

American Talent highly appreciated in Europe.—Dr. Rush's *Medical Philosophy*; Dr. Wistar's *Anatomy*; Swan on *Vaccination*; Chapman's *Therapeutics*; Bigelow's *Botany* and Potter on *Contagion*, have been republished in Great Britain; and the last mentioned having gone through several London editions has been translated into French, and published at Paris, and into German, and published at Leipzig.

The town of Bristol (England) is to be lighted with gas. A capital of 10,000 pounds has been subscribed by a company for this purpose.

A serious misunderstanding exists between the Prince of Brazil and the Portuguese Cortes. The former has shewn a disposition to render his government independent of the mother country, and the latter have decreed that the delegated authority of the Prince shall immediately cease, and that he shall return to Portugal in the course of four months.

Havana is said to be greatly infested with robbers, who commit nocturnal depredations, keep the inhabitants in a state of constant alarm, and are sometimes too powerful for the control of the police.

A profitable commerce is now carried on between some of the ports in the Southern states and the West India Islands belonging to the British. The *Bahia Register* says, "one small vessel carried out a cargo of timber which cost \$500, and returned with West India produce worth \$3,000."

A dreadful storm has occurred in the neighborhood of Calcutta, in which from 16 to 17,000 houses were destroyed, and more than 12,000 men, women and children. The loss in cattle, grain, &c. was also very great; and those who escaped the inundation are threatened with famine.

Poison.—Mr. Edmund Jukes, a surgeon of Westminster, Eng. has invented an apparatus by which the stomach may be emptied of poison, received by accident or design. After trying it on various animals with complete success, he experimented on himself—and swallowed ten drachms of laudanum, from which he was promptly relieved.

A foot race between a York-hire-man and a Lancashire-man was lately run at Doncaster. The purse was 20 guineas. The Yorkshire-man won the race by 160 yards. Time, 20 minutes and 35 seconds, for 4 miles.

Longevity.—There is now living in the state of Ohio a poor old woman, named Ann Bailey, who is supposed to be about one hundred and twenty years old. She was about 12 or 13 years old, when Queen Anne of England died, after whom she was named. She still retains so much health and strength as to sometimes attend market with a few fowls, &c. making a journey on foot of about seven miles to dispose of her articles, which she carries on her back.

Since the first of January, sixty-seven of the officers of the U. S. Navy have died.

At Schenectady, N. Y. *Fair*, a bull calf was exhibited, for which the owner refused to take \$350.

Miss Harrison, of America, N. Y. has made an imitation Leghorn for which she was offered \$150. She was ten weeks in completing the work.

M. Guy Duplantier, of Louisiana, has invented a machine for making bricks, which, it is said, will do as much work as 30 men. Also, another machine for piercing or morticing fence posts, in which he applies the power of horses, as it is said, to great advantage.

Rot in Cotton.—A Mississippi Cotton Planter, who was curious enough to watch the motions of a species of bug hovering round the cotton trees, has published, in the Port Gibson paper the result of his observations, by which it appears that the rot in cotton is caused by the sting of a bug, which, piercing the tender covering of the boll, in its unripe state, produces, in the course of three days, the decay of the bowl.

Gigantic Vegetable.—A beet which grew in the garden of Mr. Daniel Kramer, of Northampton, Pa. and which is now to be seen at his house, weighs fifteen pounds and a half, and measures at the thickest part thirty-four inches and a half, and somewhat lower down, twenty-seven inches. Who can beat this?

Philadelphia Union.

Ans. Massachusetts, N. Hampshire, and we believe every state in New England can beat the Pennsylvania beet all hollow. Mr. Leonard Fratt, of Pembroke, N. H. raised a beet weighing 92 pounds, and Mr. F. N. Chadwick, of Hanover, Mass. a beet which weighed 21 pounds. Therefore the Pennsylvania beet is by no means the beat of all beets.

FOR THE NEW ENGLAND FARMER.

THE SCOLDING WIFE.—A Sentimental Sonnet.

Hoarse thunder howls, blue lightning flashes,
Against the stars vex'd ocean dashes,
Earth, sky and sea, fire, water, air,
Like tipsy Irish, at a fair,
Are all engag'd in one great clatter,
And every particle of matter
Seems warring wild with every other
To make one universal pother!
The great globe rent, the chasm displays
All Pluto's regions in a blaze,
Earthquakes have split the pole to shivers,
And all the solar system quivers!
But surely this vast elemental strife
Is wrought contrived with a scolding wife.

FOR THE NEW ENGLAND FARMER.

A special good reason for Self-Puffing.

Jack is a curious kind of elf,
Who, though he likes to puff himself,
Does it from principle, not pith;
He knows his worth, like insect small
Can never be discern'd at all,
Unless 'tis greatly magnified.

FOR THE NEW ENGLAND FARMER.

IMPROMPTU.

On seeing a prize-proud blackhead taking a solitary airing in his own coach.

Things have come, now-a-days, to a pitiful pass,
Since it takes two fine horses to draw one vile ass!

Private happiness is the only sure and permanent basis of public prosperity.

Every day feelings and fire-side enjoyments decide the tenor of our lives, and he who values them most plays the best stake for happiness.

Madam Terein, a lady of erudition and discernment, gave to Marmontel, when he was a young man, a piece of advice with respect to the management of authorship, which ought to be a perpetual lesson to all writers by profession. "Secure yourself," said she, "a livelihood, independent of literary successes; and put into the lottery only the overplus of your time; for we to him who depends solely on his pen—nothing is more casual. The man who makes shoes is sure of his wages; but the man who writes a book is never sure of any thing."

It is not necessary in order to be an agreeable companion that you be either eloquent or witty, or possessed of any rare or superior talents; all that society demands of you is that you be complaisant without meanness, polite without flattery, steady without rudeness, and cheerful without affected gaiety.

Court the company of the learned, and the conversation of the aged; their discourse is often more useful than any book you can read.

It is a sure sign of want of wit, when one is always attempting to shew it.

The matrimonial blacksmith of Gretna Green, having bound an old lady, and a youth of unrazed chin in the silken bands of matrimony, observed to a friend, "I have just tied a withered stick and a green twig together with a red web."

From the Connecticut Mirror.

The Hon. Tristram Burges, of Providence, delivered an Address in August last, to the R. I. Society for the Encouragement of Domestic Industry, and a copy has been sent by Messrs. Miller & Hutchens, to the Hartford County Agricultural Society. The following is part of it:

"I fear we shall find, we are, taken in a mass, about such farmers as our forefathers were when they migrated to this country. They, we know, were such farmers as their fathers were when they left England. But all the capital improvements in agriculture, have been made, in that country, since the settlement of this.

If it were in the course of nature for the venerable pilgrims of Plymouth, again to land on the shores of that island, they would not know the fields of their native country. Not many years before they migrated, the London market was supplied with vegetables from Flanders, and the English climate and soil were deemed incapable of producing them. At this time, 14,000 acres are appropriated to gardening in the immediate neighborhood of that metropolis, and the vegetables and fruit raised on those lands are sold in that city for a sum little short of four millions of dollars per annum. The rent of land in the county of Norfolk, the least fertile, but the best farmed district of England, has increased within the memory of man, eight fold. The rent roll of Mr. Coke, the great Norfolk farmer, has, in that time, risen from five to 10,000*l.* per annum. This has been done, not by grinding his tenants, but by enriching them; by granting them leases of his lands for twenty years; and by giving them, in his own farming, a great example of the immense agricultural improvements which may be made, even in the sands of Norfolk, by industry, skill and capital.

Scotch farming has come into existence, long since Roger Williams paddled his canoe round Fox Point. In those days, the Thistle was the national emblem of Scotland. They fought under it in war, and foraged upon it in peace. But the unpoetical farmers of Caledonia have lost all delight in pursuing the thistle's beard, with the heroes of Ossian; or sleeping on the blooming hether with the buccaniers of Roderick Dhu. They have ploughed down all those things, which look so pretty, and smell so sweet in song, and given up those haunts of the muses to plant English barley and wheat; Dutch and Swedish turnips; the clover of Flanders, and the Shamrock of Ireland. In the progress of these improvements, these men have done, what Scotchmen think an essential service to that country; but what American farmers would think a curse to this—they have, by increasing a demand for labor, nearly doubled the price of it; but these industrious, intelligent Scotchmen, with their national prudence, have contrived, not only to pay this augmented price of labor, but to replace all their capital, and add to it, at least fourteen per cent. per annum. A farmer in the Lothians of Scotland, who cultivates 700 acres of land at a rent of 1*l.* 10*s.* sterling per acre, will, at the end of the year, have in his pocket, clear of all expenses, more than \$3,500. He has so much to add to his capital, and to enable him to extend his cultivation."

From the Plymouth (England) Telegraph.

We last week noticed an invention by a gentleman of Plymouth for conveying the electric

fluid by means of a copper conductor fixed in the masts, through the bottom of ships. Instead of being ascribed to Mr. T. Harris, Jr. as then stated, it should have been Mr. W. S. Harris.—The experiment took place on Monday last, on board the Caledonia, in the presence of the Navy Board, Sir A. Cochrane, Commissioner Shuld, several Captains in the Navy, and the principal officers of the Dock-yard, in the following manner: The Louisa cutter having had a temporary mast and topmast fitted with a copper conductor, according to Mr. Harris's plan was moored astern of the Caledonia, and at the distance of eighty feet from the cutter a boat was stationed with a small brass howitzer. On the tiller-head of the Caledonia were placed the electrical machine and an electrical jar with the outer coating of which a line was connected, having a metallic wire woven in it this line being carried out of the starboard window of the wardroom, terminated in an insulated pointed wire in the immediate vicinity of the touch-hole of the howitzer; a similar line was passed from the larboard window, which communicated with the mast-head of the cutter and at the termination of the bolt through the keel a chain was attached, connected with another insulated pointed wire in the boat, placed in the vicinity of the touch-hole—the space between the insulated points being the only interval in a circuit of about 300 feet, from the positive to the negative side of the jar. Some gunpowder being placed in contact with the conductor in the cutter, and the priming in the interval of the insulated points, the jar was charged, and the line attached to the mast-head of the cutter being brought into contact with the positive or inside of the jar, a discharge of electric matter followed, which was passed by the line to the mast-head, and by the conductor through the powder to the chain in the water by which it was conveyed to the interrupted communication in the boat, where it passed the form of a spark, and discharging the howitzer, returned to the negative or outside of the jar by the line leading into the starboard window, thereby demonstrating that a quantity of electric matter had been passed by the conductor through the powder (without igniting it) in contact with the mast of the cutter, sufficient to discharge the howitzer. Mr. Harris then detached the communication between the keel of the cutter and the positive wire in the boat leaving that wire to communicate with the water only; but this interruption did not impede or divert the charge, as the discharge of the howitzer was effected with equal success as the first instance, the water forming the conductor from the cutter to the boat. In order to demonstrate that a trifling fracture or interruption in the conductor would not be important, it was cut through with a saw; but this produced no material injury to its conducting power.

These trials, carried on under the disadvantages of unfavorable weather, could not fail of convincing all present of its efficacy, and called forth the decided approbation of the Navy Board in particular, which was evinced by Sir T. B. Martin requesting Mr. Harris to superintend the equipment of the Minden and Java frigates, preparatory to its general introduction into the navy.

The science of love is the philosophy of the heart.

NEW ENGLAND FARMER.

VOL. I.

BOSTON, SATURDAY, NOVEMBER 30, 1822.

No. 18.

DR. MITCHELL'S ADDRESS,

Delivered before the N. York Agricultural Society, November 12, 1822.

Gentlemen of the Society, and Fellow Citizens,

Addresses, on occasions like this, have become so common, that it is almost to be regretted the call for them has not ceased. Yet it seems difficult to close such a scene as the present, without offering a few observations, particularly as they are prompted by the surrounding objects. Indeed, if remarks on the improvements already made, and rapidly making among us, have any pertinence or value, now is the proper time to offer them.

I was always friendly, as I still am, to the public patronage extended by law to societies for promoting the interests of agriculture and the useful arts. It manifests a liberal and noble spirit—it invites the citizens to exertions they would not otherwise make, and as it is not compulsory, they can decline acceptance if they disapprove the terms.

In acceding to the conditions, our association has shewn its good sense. A spirit of emulation has arisen which has produced excellent effects.

Persons have been brought together for laudable purposes, who would otherwise never have met. Productions and articles of various kinds have been offered for exhibition, which could, only in this way, have been viewed to so much advantage.

In all these displays it becomes us to acknowledge the goodness of the almighty Ruler of heaven and earth, who enables his creatures to advance in wisdom and skill, as well as in virtue and piety.

I congratulate you on the appearance of general advancement in the business of the society. The highways are very much mended; the strata of granite and gneiss have been broken up and converted into stone-fences. Bridges of the best construction connect the opposite shores of some rivers; and ferries of modern excellence offer remarkable facilities for crossing the waters of others. The ease, safety and speed of travelling are increased, and the condition of inclosures, buildings, forests and fields, evince the good order of farmers.

As indications of the prevailing spirit, I bring to your recollection the periodical works devoted to the cultivation of land, the due application of labor, the introduction of better machinery and implements, and the multiplication of valuable produce, which do honor to their respective editors in Albany, Baltimore and Boston.—It is a reasonable expectation that the proprietors of the soil in all the states, will extend an increasing patronage to such respectable and instructive publications.

It is pleasing to notice the Horticultural Society established in this county, and pursuing successfully its object. The exhibitions of the produce of gardens during the season, have enabled the directors to present interesting reports to their fellow citizens. It would seem that such laudable exertions must have a highly beneficial effect upon the market, both as to

the quality and quantity of the articles. In a survey like the present there is a peculiar delight in noticing the mechanical and scientific institution now organizing for instructing tradesmen and citizens in those principles of nature, which elucidate the processes of art. The well directed efforts of the managers merit applause, and cannot fail to be servicable to the great cause.

Our own premiums for butter have excited strong emulation among the proprietors of dairies. It is ascertained that it can be prepared in as neat and exquisite a style, as in any other place. And whenever the purchasers shall be willing to pay the additional expense, it may be decorated with prints, and refrigerated with ice, to suit the most refined taste.

Allied to this is milk, the daily supply of which to the inhabitants of a populous city, is more considerable than is generally supposed. Considering the extensive and perpetual use of this liquid, I wish it had been ascertained by fair experiment what course of keeping and feeding would be best for the cows which afford it.

I am peculiarly pleased with the bonnets now as well as heretofore offered at our show. It has been the good fortune of our ingenious females, among whom I mention Misses Harrison, Hedges, and Babcock, to discover that the *bent-grass*, (*agrostis*.) and the *spear-grass*, (*poa*.) are excellent materials for the manufacture. The Tuscan fabrics that we receive from the banks of the Arno, through Leghorn, are made of the straw from a dwarf variety of wheat, (*Triticum*.) As far as I can judge, our native grasses may be worked and bleached into forms quite as beautiful as the wheat. I hope they will be found to possess more toughness and flexibility, wear better, and last longer. The raw material is cheap: the quantity inexhaustible. We must leave to the patience and skill of the ladies the determination of the question how far it may be practicable or expedient to establish manufactories among us. My feelings and wishes are in their favor. I trust they will grow and thrive.

From the excellence of the works in silk before us, we have full proof that our artists are proficient in dyeing and weaving. Whenever the state of society shall arrive in which the culture of this article shall be found profitable, we already know that both the tree and the animal are congenial to our climate. The white Mulberry grows perfectly in our soil, and the Bombyx prepares its cocoon as completely as in any part of the world. It is delightful to contemplate the resources of future industry, and to behold through the glass of prophecy, this family of insects, labouring under proper direction for the comfort and decoration of the human race. I observe with what satisfaction you beheld the vest patterns, the watch ribbands, the sewing-silk and other articles. The fabrics of cotton afford matter for the most agreeable reflection.

The plant whose seed is enwrapped and cradled as it were, by the precious down, has become naturalized to the more southern states. Though the *Gossypium* displays its yellow blossoms, and discloses its ripening capsules occa-

sionally in New-York, there is reason to believe that it cannot be relied upon as a crop, by reason of the early frosts, further north than the banks of the Roanoke. We receive it, however, in vast quantities, of various qualities, and upon the best terms, from Charleston, Savannah, Mobile, New-Orleans, and the other parts of the regions where it grows, since its introduction into Georgia by my friend the late Governor Milledge. The arts of spinning, colouring, weaving and putting up the goods, seem to be fully understood. A strong recommendation of our domestic articles of this class, is the better twist of the thread, and the more compact texture of the web; whereby it has a decided superiority over the starched goods of England, and the fleazy ones of India. An examination of the Sheetings, Shirtings and Gingham before you, has verified this remark.

Wool, and its fabrics, have acquired, as they deserve, a high share of consideration. In a country subjected to the influence of cold for nine months, and of fashion for the whole twelve, the manufacture of clothing from this material, is a business of high moment. Accordingly it has attracted a corresponding degree of attention. Foreign wool, is admitted free of duty. In addition to the varieties of sheep, whose fleeces are of a longer and coarser staple, the merino breeds of Spain are now domesticated for furnishing the material of the finer fabrics.—Ware houses are established for buying and selling the tools and utensils of the trade, as well as the different kinds of the staple. Manufactures have grown up to respectable and encouraging height. And the stockings, the flannel, the coatings, the blankets, the carpets and broad-cloths, are among the things which bear witness of the skill, the industry, and the capital employed.

I cannot forbear to notice the machines invented to facilitate the dressing of the bark, rind, or cortical part of flax, by several persons at home and abroad. The price of linen cloth is so high, that the patriot and economist will agree in opinion that all practical efforts to reduce the extravagant price of this elegant article of dress, are worthy of special countenance and regard.

Hemp, I rejoice to assure you, may be raised to any requisite amount, as New-York and Kentucky have abundantly proved. If henceforward we derive it from Russia and Poland, it will be imported from the convenient exchange of commercial objects between friendly nations, rather than from any necessity we are under to procure from that source cordage or canvas for our shipping.

Our works in wood are admirable. Ships, carving, cabinet-ware, household furniture and utensils, squared and sawed lumber, staves, masts, yards, and the almost numberless fabrics of wood, are a mighty and important article of our domestic produce, proving the excellence and variety of the raw material, and the ability of the workmen to improve it. The barrels, casks, hogsheds, trays, ladles, spoons, boxes, and baskets, may be considered as samples of this interesting art, in certain branches of which

the religious and laborious society called *Shakers* has attained an honorable distinction. Cork may be here mentioned, whose operations are conducted with remarkable excellence, and to a great extent. Works in leather have been offered to you. It is not my intention to enter into a disquisition upon the methods pursued for tanning, tanning, or otherwise preparing the raw hide of an animal. Suffice it to observe, that the government does not require any duty on imported skins; that they are converted into materials for the best of fabrics, by our tanners and curriers; and that the cordwainers and stitchers transform them into shoes, boots, harnesses, caps, gloves, military accoutrements, and a great variety of other important things. The oil, bark, lime, and every thing, are derived from the exertions of our fellow citizens.

I group together the metallic arts. The foundries for casting in iron, are excellent in a high degree. These, and the establishments for constructing the apparatus for steam-boats, afford topics for a discourse of greater length than the present. Gold-beating, working in silver, the making of gilded and plated wares, operations in compounding and manufacturing zinc and copper into brass, the art of the tin-plate worker, the pewterer, the type-founder, the looking glass manufacturer, the wire-drawer, the pin-maker, and a multitude more of artisans, in addition to the black-smith and the white-smith, add to the importance of this enumeration. Among these, or allied to them, I mention with satisfaction the preparations of quick-silver, antimony, sulphur, lead, potash, soda, and other articles prepared for medicinal purposes. And I add with equal pleasure, the proficiency made in the cutler's art, whereby surgeon's instruments, razors, pen-knives, and other tools of exquisite edge and finish, are duly shaped and finished.

Among the improvements whose benefits this country has already begun to experience, are the canals, or the artificial rivers, a magnificent undertaking, that is intended to connect the Atlantic Ocean by the Hudson river, with the inland waters of North America, and their dependencies through Lake Champlain and Lake Erie, the latter a length of three hundred and sixty miles. The native water-proof cement has reached us from the interior strata, and is in successful use, equal to the Roman Cement, as imported from abroad. Salt, not inferior for whiteness, purity, and flavour to the best heretofore imported from foreign places, reaches us in baskets and boxes, from the inexhaustible sources south of Ontario. Flour, as excellent in all respects, as that we heretofore received from Richmond, is brought from Utica, and other productions of prime importance, will soon follow them. The political economist gazes with astonishment upon a work which associates the eastern and western sections of our union in closer ties, which pours abundance into this city, and reciprocates the advantage by distributing plenty through all the contiguous and almost unmeasurable lands.

But I find myself obliged to turn to other objects. Our relations to the Central Board of Agriculture, and the Society for the Promotion of the Useful Arts, at the seat of our state government, continue to be interesting and important. Nor are we unknown to certain societies formed for similar purposes in governments beyond the seas.

The Gorgonists of Florence, in Italy, persist in their respectful and friendly desire, to correspond and commune with us, on husbandry, botany and rural affairs.

The National Academy of France, superintending the agronomical operations of that mighty kingdom, and the means for rendering the land more easily productive, has evinced to us the desire felt by the royal establishment, to learn what is doing here in the same department of occupation and research, and to partake of all the consequences of a liberal intercourse.

In like manner, the Imperial Society of Agriculture, for Austria, in sending us their statutes, catalogue of members, and volumes of transactions, have made an overture toward an acquaintance, which I am proud to announce and desirous of imitating.

The exhibition of domestic animals, the kine, sheep, swine, and horses, are highly honourable to the care and judgment of the breeders.

Permit me while I am addressing you, gentlemen to make a few suggestions for your consideration.

The axe and the firebrand have been employed with such destructive fury against the forest which the first settlers began to encounter, that fuel has grown dear and timber is become scarce. The culture of the Locust, the Chesnut, the Hickory, the Blackwalnut, the bass wood, and the oak, would well reward the planter, and secure wood for its various purposes to his estate and his successors.

There is such heavy damage and loss, by the voracity of vermin, that measures for destroying these noxious animals, or for preventing their ravages, ought to be speedily adopted. Insects are the chief of these mischievous agents. Almost every vegetable, whether wild or cultivated, has its attendant insects or troop of insects to prey upon it. Their history deserves to be better known. Their metamorphoses, through their fourfold state of being call for an exact series of observations. All the species, in their several forms of existence, ought to be collected into museums for instruction. We should then know them, as it becomes us to know our enemies, and be prepared to resist their attacks. To preserve their exact form and hues, good drawings should be made and correct histories annexed. Thus the grubs and caterpillars of every insect, would be understood, as well as their state of crasis and perfect or winged evolution. The farmer might derive help from the wrens, sparrows, and other birds that live upon insects, if he would receive these visitors with kindness, and take them under his protection.

Another subject is the felicity of cultivators in the neighbourhood of the ocean. Experiments of a recent date have proved, that sea salt, applied to land, in due proportion, is a good manure. Some reports which I have read, seem to establish the fact. Experiments repeatedly made by myself, upon the rain water of this very region in which we reside, have convinced me that the fluid of showers contains a portion of this fertilizing material. This appears universally the case, in a greater or less degree, at least under all circumstances in which I have chemically inquired into it. I am satisfied the saline ingredient rises by spontaneous evaporation; and we all possess proof, that it is elevated with the spray of the sea, the wind rolls them to the shore.

A marine air is therefore charged, more or less, with this ingredient, descending in dews and rains, upon the vegetable growth below.—While we thus interpret this grand provision of nature, distributing gratuitously salt, in due quantity, with rain, to invigorate our crops, and at the same time to satiate the appetites of animals, let us understand that the operations of gypsum in the interior districts, is but an equivalent favor. There they have the sulphate of lime, and here we have the muriate of soda—with this difference, that the former requires an artificial application, while the latter is bestowed upon us without exertion or price.

With such possessions and prospects as are ours, there is no cause of envy or jealousy towards our brethren of any section of North America, or of the terraqueous globe. Our lot is cast here; and under the exercise of our faculties, our abode, during the term of our continuance, will furnish every thing that rational persons have a right to expect. And when our race shall be run, and our toil terminated in this sublunary dwelling, will commence the actual enjoyment of the treasure we have laid up in Heaven, "where neither moth nor rust doth corrupt, and where thieves do not break through nor steal."

From the London Medical and Physical Journal.

The greater facility with which zoötic pathology can be reduced to experimental certainty, makes us anxious to express our gratitude to those who pursue the subject on a rational system: on this account we cannot withhold a tribute of thanks to M. Teissier, who has lately been engaged in researches on the period of gestation of the females of several domestic animals. The following is a summary of the results:—

"Out of 575 cows, 21 calved between the 240th and 270th day: mean term 259 1-2—544 between the 270th and 299th: mean term 282 —10 between the 299th and 321st: mean term 303. Thus, between the shortest and the longest gestation, there is a difference of 81 days, that is, more than one-fourth of the mean duration.

"Out of 277 mares, 23 foaled between the 322d and 330th day: mean term 326—227 between the 330th and 352th: mean term 341 1-2 —28 between the 361st and 119th: mean term 390. Between the shortest and the longest gestation there was an interval of 97 days; as before, more than one-fourth of the mean duration.

"Observations were made on two she-asses only: one foaled on the 380th, and the other on the 391st day.

"Out of 912 ewes, 140 lambed between the 146th and 150th day: mean term 143—676 between the 150th and 154th: mean term 152—96 between the 154th and 161st: mean term 157 1-2. Here the extreme interval is only 15 days, to a mean duration of 152; that is, only one-tenth.

"The mean term of seven female buffaloes was 308 days, and the extreme difference 27 days.

"The extreme gestations of 25 sows were 109 and 143 days.

"The extreme terms of gestation of 172 rabbits were 27 and 35 days; difference 8.

"In the duration of the incubation of domestic fowls, differences of from 5 to 16 days were observed. These cannot be ascribed to acci-

dental differences of temperature; for, according to the observations of M. Geoffroi de Sainte Hilaire, the same differences are found in the duration of the development of the chickens hatched by the Egyptians in ovens.

"From the whole of his observations M. Teissier infers, that the period of gestation is extremely variable in every species. Its prolongation does not seem to depend either upon the age, or more or less robust constitution of the female, or upon the diet, the breed, the season, or the bulk of the fetus, and still less upon the phases of the moon."

When we consider that in the inferior animals most organic actions are more regular than in man, we can now no longer be surprised at the uncertainty which sometimes attends the period of gestation in the most experienced matrons. May there not be the same variety in the growth of the fetus as in the child before puberty?

It is inconceivable what effect lime has on the productiveness of the earth. Philosophers have investigated its nature and properties, to find out the secret spell by which it works; and while some have attributed the effect to its power of decomposing putrescible matter, or to its affinity for carbonic acid, others have ascribed it to the change effected on the constitution of the soil. All, however, are agreed, that no land, after its first and natural richness has been exhausted by cropping, can continue fertile without a mixture of this fossil. Its use was the first thing which revived English agriculture after it had long languished in the most abjected state; and the first thing too, which raised Scotland to opulence and independence. Lime, as a manure, has found its way into France and Germany; and it is blended with the soil along the shores of the Baltic. In southern latitudes this mineral manure is more generally applied, either incorporated with clay in the shape of marl, or combined with the sulphuric acid in that of gypsum.

Lime is found of extremely different qualities; and in proportion as science comes to enlighten our practice, we will turn our attention to the character of the rock from which this fossil is taken. Pure limestone consists of nine parts of carbonic acid, and eleven of calcareous earth; and of course, in the process of burning—which is employed solely to expel the acid by the action of red heat, it will lose 9-20ths of its specific weight as drawn from the kiln. Shells of first quality will require more than their own weight of water to slake them; and every one bushel, when reduced to powder, will measure three. When the lime is intermixed with sand, flint, or clay, its loss in calcination will be less, the shells will yield a smaller proportion of powder, and what is still more curious, will require a less quantity of water. As there are great inequalities in the mixture of these foreign ingredients, so the product in powder and the quantity of water used in slaking, may be employed as certain measures of the value of the limestone.—The color, to a certain extent also, ascertains the purity; but this cannot be relied on infallibly, as there may be a portion of magnesia in combination, which, on account of its equal whiteness, cannot be discriminated by the eye. It is plain, that when our different rocks come to be wrought, these tests will be of

infinite advantage, and point out to the farmer and mason, those which will yield the most calcareous earth—the substance which both of them are in quest of, for the purposes of their respective arts.

To the farmer it is an object, to cart the lime, when fresh from the kiln. By exposure to the atmosphere, this earth attracts carbonic acid, and returns to its original weight, usually in the proportion of a twentieth part of each of the first five or six days; but if spread out to the air, recovers it much more rapidly. While it is light of carriage, it should be transported to the soil with which it is intended to be mixed, instantly slaked, and then scattered and harrowed on the surface. Delay here is of pernicious tendency if inert vegetable matter is to be acted on; as the causticity of the lime or its power of decomposing animal or vegetable matter, is most active in its simple state, before its affinity has been exerted on the carbonic acid of the atmosphere; but if the application is meant to improve the earthy texture of the soil, or to supply calcareous matter to the vegetable organization, there is no necessity for such haste, as this fossil, considered as a carbonate, is of infinite value to the farmer, and moreover is supposed by some inquirers to be peculiarly useful in this latter case. Directions* are even given against using it in the former particularly in soils rich in putrescent manure, because it lessens the solubility of those compound products that go directly to the nutriment of the plant.

*Davy's Agricultural Chemistry, page 320, 321.

Letters of Agricola.

From the Providence Journal.

The President of our University has, from experiments in Hydraulicks, discovered an improvement in Flumes, which, at most mills, perhaps all, will increase the force of the water, and, at some will double or treble it. Where mills are now in operation, this improvement may produce a small expense. For this discovery, he has, we learn, obtained Letters Patent from the President of the United States.

Rice Glue.—An elegant cement may be made from rice flour, which is at present used for that purpose, in China and Japan. It is only necessary to mix the rice flour intimately with cold water, and gently simmer it over the fire; when it readily forms a delicate and durable cement, not only answering all the purposes of common paste, but admirably adapted for joining together paper, cards, &c. in forming the various beautiful and tasteful ornaments which afford so much employment and amusement to the ladies.—When made of the consistence of plastic clay, models, busts, basso relievos, &c. may be formed and the articles when dry are susceptible of a high polish and are very durable.

Portland Gazette.

Manufactures & Agricultural varieties.—Among the articles which obtained premiums at a late agricultural fair in Alleghany county, (Penn.) were *Japanned Waiters and Trays*, made at Pittsburgh; *Castor Oil*, from fifteen acres of beans raised in that county; and *Segars* from tobacco also raised in that county.

N. Y. Statesman.

Water.—A late English paper says, "Recent experiments, in many parts of England, have proved, that supplies of the best water may be obtained by properly boring the earth to a sufficient depth. The expense appears to be trifling, while the result is of the highest importance to all landed property. Fountains have been made in parishes where water has usually been sold by the gallon, which yield a constant supply, the year round, of a hogshhead per hour."

This appears probable enough, when we call to mind how salt water is procured throughout the western states of the union.

Niles's Register.

On Wednesday last, a highly interesting experiment was made with a machine, constructed by Messrs. Panton, Murray and Wood, of this place, under the direction of Mr. John Blenkinshop, the patentee, for the purpose of substituting the agency of steam for the use of horses in the conveyance of coals on the iron rail way, from the mines of J. C. Branning, Esq. at Middletown, to Leeds. This machine is, in fact, a steam-engine of four horses' power, which, with the assistance of cranks turning a cog wheel, and iron cogs placed at one side of a rail way is capable of moving, when lightly loaded, at the speed of ten miles an hour.

At four o'clock in the afternoon, the machine ran from the Coal-staith to the top of Hunstlemoor, where six, and afterwards eight waggons of coals, each weighing 3 1-4 tons, were hooked to the back part.—With this immense weight, to which as it approached this town was super-added about fifty of the spectators mounted upon the waggons, it set off on its return to the coal-staith, and performed the journey, a distance of about a mile and a half, principally on a dead level, in twenty three minutes, without even the slightest accident. The experiment, which was witnessed by thousands of spectators, was crowned with complete success; and when it is considered that this invention is applicable to all rail-roads and that upon the works of Mr. Branning alone, the use of fifty horses will be dispensed with, and the corn for the consumption of at least two hundred men saved, we cannot forbear to hail the invention as of vast public utility, and to rank the inventor amongst the benefactors of his country.—*Leeds Mercury.*

A young lady in London, who was handsome, and had a fortune of £12,000, while she was buying some small articles of a young shopkeeper, with whom she had some trifling acquaintance, took a piece of Flanders lace, and, out of mere gaiety and frolic, went hastily out without paying for it. The shopkeeper, who had a good head for speculation, followed and seized her, and charged her with the theft; and in a serious and peremptory manner, said to her, "Miss, you may take your choice, either to go with me before a magistrate and suffer the penalty of the law for stealing my lace, or go before a clergyman and marry me." After a short pause, (and who could blame her?) she chose the latter.—*London paper.*

A red cedar gate-post has lately been taken up at Philadelphia, fit for fresh use, which was put down 90 years ago. It is to be marked for further experiments.

From the National Regis.

MINERALOGICAL.....No. III.

The connection between practical Agriculture and the theories of science is too extensive to be brought into view in the narrow limits of a single essay. To develop all the causes of sterility, to examine the qualities essential to a good soil, to correct and neutralize those which are injurious to plants, would require a detailed investigation of the laws of vegetable economy. Inquiries like these are interesting in the pursuit and valuable in their results. When they shall have been cultivated by those who possess the taste and the patience so necessary to their successful prosecution, by those who can trace the various operations constantly going on in the great laboratory of Nature, those difficulties which now perplex and discourage will be overcome, and the art of scientific cultivation will be reduced to established and fixed rules, as simple as the axioms of Mathematics. The remarks which have been made, and the examples which have been adduced to show the advantages which would flow from the study of Mineralogy, so far as it relates to the knowledge of soils and the adaptation of plants to their varieties, have been brief and few, and the view which has been taken of the subject hasty and imperfect. It will not, however, have been useless if it should have directed the attention of the intelligent to an object well deserving examination.

It remains that we point out some of those mineral productions of our neighbourhood, which may become sources of profit, either as applicable to the amelioration of the earth, or from some adventitious circumstance which may render them valuable. This portion must from necessity be even more imperfect and defective than the former. Observation has not yet been employed in the search for those treasures which are hidden in the deep recesses of our hills, or in the caverns of the rocks. The hammer of the Mineralogist, whose peculiar province it is to discover the hiding places of the gem and the metal, has never yet been heard in our shady forests or silent valleys. The eye of curiosity has not yet explored those situations, where the ores were deposited when the mountains were piled upon their foundations. It cannot be said that this section of our country is rich in minerals, for there is at present too little known of those beneath its surface, to justify the assertion. Certain it is, that it possesses some which must form important articles of commerce, of manufacture, and increase the wealth and resources of its industrious and prosperous inhabitants. No regular examination has yet taken place, and for our knowledge of those which most readily present themselves to notice, we are indebted to accidental curiosity.

The art of mining has as yet received but little attention in this country. Young and growing as it is, labour is occupied in the clearing and improvement of the earth. It is not to be expected that were all are busied in strewing the seed into the furrow and gathering in the abundance of a generous harvest, that researches which are generally, though erroneously considered as uncertain and hazardous, should be undertaken, or if commenced that they should be prosecuted with the skill and zeal so essential to a successful issue. Popular superstition has guarded the beds of the jewels

with so many fanciful beings, the offspring of heated imagination, and peopled the dark habitation, of those metals whose utility as media of exchange, depends entirely upon their scarcity, with so many protecting spirits, that it requires no small degree of courage in adventuring to invade the dominions of those powers, who were supposed to be ready to inflict punishments on those who would steal from them the treasures they are commissioned to keep. It is amusing to find how many stratagems credulity and ignorance have put in practice, to deceive their vigilance. Some have dug deep at midnight, in places where a little experience must have convinced them, that nothing existed to reward their toil, thinking these subterranean divinities might be then slumbering on their posts, and afterwards have laid the burden of their disappointment upon the omission of some mysterious ceremony, instead of fathoming it upon their own folly. The art of farming is a distinct profession, and requires experience for its practice. Nor is an acquaintance with its rules valuable to the farmer, except as furnishing him with an uncommon method of rendering his farm productive. If portions of it are barren in consequence of mineral substances, instead of wasting labour in the attempt to render its soil fruitful, he may go beneath and gather crops more valuable than those of the corn or potatoe.

One of the sinews of agriculture, indeed the spring which sets all its various implements and machines in motion, is Silver. This article has been a native of Worcester County. In the year 1751, a vein of this metal in combination with iron and lead, was discovered in the shire town passing down into a hard rock of that description denominated Quartz. A shaft was sunk to a considerable depth, by a company formed for the purpose of working a mine on the spot.— Tradition does not inform us why it was abandoned; whether on account of the small quantity of ore obtained, the expense of excavation, or the want of sufficient skill in those employed. Examination of the specimens which are still found about the mouth of the opening, shows that about 2 parts of 100 are silver, the remainder Iron, Lead, Sulphur and Arsenic. How far it is fair to judge of the ore as it came from the mine, by these pieces, which were undoubtedly thrown aside at the time of working it, as not suitable for melting, it is not easy to decide. It is said that the same metal was found at other places not only in the same town but in other parts of the county.—Lead has been noticed in union with other minerals, but not in quantities sufficient to induce the belief that it could ever become important.

It is a remarkable fact that Iron, the mineral most useful to man, is most widely diffused over the earth. Forming as it does a necessary of his existence, employed as it is in every art, being the material for supplying the instruments for every manufacture, it is most providential that it should be thus distributed over the face of the globe. In this county it exists in almost every stone, ledge, and hill. It gives a bright red to our walls, it tinges our soils with a yellow shade, it communicates its taste to many of our springs, and with sulphur forms those beautiful cubes which from their color and lustre might be easily mistaken for gold. Furnaces have been erected in some parts, and the abun-

dance of the metal would justify the establishment of many more.

Arsenic is also found, not in its native and pure state, but in union with other metals, communicating to them a white color and a peculiar odour.

Lime is most important in its economical application to the common purposes of life. Every one knows its use in architecture and how much it contributes to the durability and convenience of buildings. All are apprised of the advantages resulting from its agency, in increasing the harvests, and forwarding the maturity of vegetables. This mineral in the state of the Carbonate, is found in the Northern part of Worcester county. When employed as a cement, it is not inferior to the Lime of any other section. As yet it has not been used as a manure long enough to test its properties.— From the quantity of Magnesia with which it is mixed, its success on some soils would be doubtful.

Clay is one of the most useful substrata of our meadows at a certain depth. Besides the ease with which it is converted into a material for constructing edifices, it is valuable for changing the texture of those fields which do not retain moisture. The Marl which is prized so highly in those situations where it can be obtained, is composed of Clay and Lime. Of the good qualities of this earth, and of the astonishing effects which it has produced, much has been said, by foreign writers. As the two ingredients which are its components, exist in their separate state, in abundance, it is not a very rash prediction, that they may be found united in such proportions, as to form a substance of all others, most necessary to the Farmer. The conclusion is so rational that they may be found thus mixed, from the fact that minerals readily change characters and intermix freely with each other, that it would well repay the time and attention necessary for the examination of our argillaceous earths.

The same remark is applicable to the Plaster of Paris or Sulphate of Lime. Sulphur or its acid, combined with Iron, glitters on almost every wall, or tinges the rocks with its yellow hue, and Lime is found in vast beds in this county. From these circumstances, a strong probability results, that there are situations, where the hand of Nature may have mingled together these ingredients, and that the Gypsum may be obtained nearer than Nova Scotia, and at a less expense than the price it would command, even when transported by water.

That these assumptions have no better foundation than conjecture, must be confessed. How far they are reasonable every one can decide for himself. Two minerals are seldom found in the same locality, entirely separate from each other. A transition carries one into the other, so that it is difficult to determine where one ends and the other begins. In these situations the qualities of both are blended together. The affinities which some substances have for others dispose them readily to unite. The subject deserves some attention, and should the opinions that have been advanced be established by experience, the advantage would exceed calculation.

The enumeration will be continued in our next number.

A FARMER.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.

FOR THE NEW ENGLAND FARMER.

FRUIT TREES.

"The seeds of a nursery should be planted in rows five or six feet apart, that carrots, potatoes, or bush beans may be planted between them. This will be an inducement to keep the nursery clean. Cherries, peaches, plums, and other stone fruit, should be planted while the bones are moist, or with the meat on them. In this way they come up with more certainty. It is a good practice to plant the seeds in beds, and to remove the young trees to the nursery. This will give an opportunity of early removing the tap root, and of increasing and directing the lateral roots. The dwarfs in a nursery are not worth cultivating, and ought to be removed; there are commonly enough thrifty trees without them.

"In taking up trees, care should be used not to injure the roots. The tap roots should be cut off, the broken roots pruned with a sharp knife, and the lateral roots should be carefully preserved, and should have sufficient room in the ground to spread. The trees when set out should have the same aspect, as when standing in the nursery. It is useful to place a small quantity of hay or straw around them, to prevent the sun from taking up too much of the moisture, and to keep the ground from becoming dry and hard. This should be removed before snow falls, lest it harbor mice. On dry land, not exposed to be moved by frost, transplanting is safest and best in autumn; otherwise in the spring. Trees are more thrifty, will bear sooner, and more plentifully, near fences, and will less incommode the cultivation of the field.

"In forming the head of the tree, all the limbs, which will be likely to rub across other limbs, should be early removed. By neglecting to do this in season, the tree may be injured by causing large wounds. By pruning when the circulation is most active, the wounds will soonest be healed. It is safest, when the wounds are large, to cover them with some kind of plaister to keep out the water and air, and prevent rotting. Mature trees, it is said, will produce more and fairer fruit by being pruned when in blossom.

When mice have injured the bark, it is useful to cover the wound with dirt, or some kind of plaister. When entirely girdled, the tree may be preserved by connecting the under and upper lips of the bark with a suitable number of scions. It is a good preservation against injuries by mice, to tread down the snow, when it first falls, for a foot or two about the tree."

Address by Rev. Abel Abbot, to the Essex Agricultural Society.

*For a recipe for preserving trees from mice, see No. 16, p. 123.

TO REMOVE FRUIT STAINS OR IRON MOULDS FROM LINEN OR COTTON CLOTHS AND OTHER SUBSTANCES.

Moisten the spot with water, and hold it in the fumes of a brimstone match. If a red rose be held in the fumes of a brimstone match, the color will soon begin to change, and at length the flower will become white.

Muriatic acid (spirit of sea salt) removes the stains of common ink, but it does not affect

printer's ink. It is therefore recommended for cleaning old books and prints. Half an ounce of red lead being added to three ounces of common muriatic acid renders it fit for this use. If indigo and oxid of manganese be added to common ink, it will prevent its being effaced by muriatic acid.

The citric acid (lemon juice) is proper for removing ink-stains from linen, but they are best removed soon after they occur. If they remain long in the cloth, the iron in the ink acquires that degree of oxidization, which renders it insoluble in acids. When ink stains have thus become what are called *iron moulds*, they may be removed by oxalic acid (a substance extracted from sorrel) or by first washing them with a sulphuret of potash (formed by triturating or pounding together equal parts of sulphur and pure potash, till the mixture becomes green) and then applying the citric acid as usual.

ANTIDOTE AGAINST CONTAGION.

An English chemical work of high authority, states that "accounts have been received from Spain, that in the midst of the dreadful contagion which reigned in that country, the inhabitants of those houses, where fumigations of chlorine gas* were used, had no attacks of the sickness, and enjoyed the best health. Care must be taken in the use of this gas, because it is so suffocating that it cannot be breathed without injury."

*Chlorine gas is produced by distilling a mixture of manganese, common salt, sulphuric acid and water. See Parkes's Chemical Essays, vol. iv, p. 69.

SUBSTITUTE FOR YEAST.

Carbonate of ammonia (or the kind of saline substance which is used in smelling bottles) is now much used by bakers in England, as a substitute for yeast.

RECIPE FOR PRESERVING LEMON JUICE OR LIME JUICE.

Strain the juice through fine muslin or filtering paper, and add as much loaf sugar as is necessary to make it sweet; then put it in a bottle which must be nearly filled, corked, waxed, tied over with wet bladder, and put into boiling water for an hour. Let it cool gradually, and put it by for use.—*Domestic Encyclopedia*.

RECIPES FOR PURIFYING PUTRID WATER.

If putrid water be agitated with a small quantity of magnesia it will lose its bad taste and smell in a few minutes. Alum may likewise be used for the purpose of purifying and sweetening water which has become fetid and unfit for use. Each gallon of water requires, according to its impurity, only from five to ten grains of calcined alum, and double or treble that proportion of charcoal, in order to render the most offensive water perfectly sweet and pellucid. The ingredients, however, ought to be preserved in close vessels, or their efficacy will be considerably diminished.

GLASS VESSELS, HOW PURIFIED.

All sorts of glass vessels and other utensils may be purified from long retained smells of every kind, in the easiest and most perfect manner, by well rinsing them out with charcoal powder, after the grosser impurities have been scoured off with sand and potash.

Crell's Journal, vol. 2, p. 170.

WELLS, HOW FREED FROM FIXED AIR.

Carbonic acid gas, or fixed air, so often occupies the bottom of wells, that workmen ought never to venture into such places, without previously letting down a lighted candle. If the candle burns, they may enter with safety; if not a quantity of quick lime should be let down in buckets, and gradually sprinkled with water. As the lime slacks it will gradually absorb carbonic acid gas, and the workmen may afterwards descend in safety.

THE BEST MODE OF ADMINISTERING OPIUM.

Citric acid, [lemon juice] has been found, within a few years to be useful in medicine. It is said that the largest dose of opium may be checked in its narcotic effects, if a proper quantity of citric acid be taken with it; and that with this addition, it induces cheerfulness, instead of stupefaction, succeeded by gentle and refreshing sleep.

Parkes's Chemical Catechism, p. 171, 10th ed

When farmers employ a great deal of lime, it sometimes happens that their horses' feet are burnt by it, which is extremely troublesome, and sometimes proves even fatal to the poor animals;* a method of preventing or remedying that circumstance will therefore be of use.

The best method of preventing any inconvenience of this sort, is to spread the lime, when in its powdery state, upon the field as evenly as possible, and allow it to lie in that state sometime before you begin to plough it. If the lime has been in fine powder it will have become effete in a week or so; after which time it will be as little corrosive as any kind of common earth, so that the horses may work among it with perfect safety—but if it has been suffered to run into clods before it was spread, these, if not broken small, will be longer in absorbing their air, and, of consequence, will remain longer in an acrid state, so that in that case the ploughing may be deferred a week or so longer; nor will it then be so perfectly safe as the other.

But if it becomes necessary at any time to plough in the lime immediately after it is spread, take care to do it only when the soil is perfectly dry; and in leading your horses to the plough, take care to prevent them from going through any wet place, so as to wet their hoofs or au-cles; for lime acts not at all upon any dry substance—but when it is in its acrid caustic state, it would corrode the hair and flesh in a moment, if it has access to water. As soon as the horses are unharnessed, keep their feet dry till you have got them carefully brushed, so as to wipe away all the dry powdery lime that may adhere to them; and if the least shower should fall, unyoke your horses immediately, and take them off the field.

But in case of any accident, by which a horse or man that is working among lime should be scalded by it, it is always advisable for every farmer, who has work of that kind going forward, to keep a tub of very sour milk or whey in some place, ready to wash the part affected with it, which will quickly destroy the poignancy of the lime, and prevent the mischief that would otherwise arise from it. The sourer the

*I have known several horses actually killed by this means, and others so disabled as never to be perfectly well afterwards.

milk or whey is, the better it will be for this purpose; it ought therefore to be long kept.* For want of this vinegar will produce the same effect, or very stale urine will be of use—but the milk or whey is the cheapest and best remedy, and ought always to be in readiness.

Anderson's Essays.

*Not too long lest it undergo the putrid fermentation which will destroy its acidity, and render it less fit to neutralize the lime, on which its usefulness depends.—*Ed. N. E. Farmer.*

PURIFICATION OF FISH OIL AND VEGETABLE OILS.

If any of these oils be boiled with tan, the tan will combine with the substance that occasions their color and smell, and the offensive matter being thus rendered insoluble will precipitate.

SALTING MEAT.

Muriatic acid [spirit of sea salt] is said by some authors to be a pleasant and wholesome condiment for food. Sir William Fordyce gives an account of a victualler who acquired a large fortune from possessing a secret that had enabled him to send out to the Indies provisions in a better state of preservation than any others of the trade. His whole secret was that of putting a small quantity of muriatic acid into each cask.—*Parkes's Chemical Catechism.*

A steel instrument may be distinguished from an iron one thus:—If a drop of nitric acid be let fall upon it, it will occasion a black spot if it be steel, but will not have this effect if it be wrought iron.

The following directions are recommended in cases of the burning of females, by their clothes having caught fire. If no person is present to assist her, she may relieve herself by throwing her clothes over her head, and laying down and rolling upon them. She must by no means run away, and flame always tending upwards, much of the mischief will be prevented if a person in that unfortunate situation will throw herself on the ground, and if possible roll about her a carpet, hearth rug, &c. If another person be present, then, without any regard to delicacy, such person should instantly pass the hand under all the clothes to the lowest garment, and raise the whole together, and close them over the head, by which, in an instant almost, the flame will be indubitably extinguished. This is the most expeditious and effectual method of preventing the dire effects of a terrible accident which is perpetually occurring.

[Or, roll the person in the carpet. This is one of the many accidents owing to the preposterous customs of open fire places, and muslin dresses in winter.—*T. C.*]

From the American Farmer.

Hints and Experiments on the selection of Seeds, particularly of Vines.

Allen County, Kentucky, Aug. 30.

J. S. SKINER, Esq.

Dear Sir—I will now give you a short account of an experiment I made with vine fruit. Having for many years observed, that some pumpkins, water melons, cucumbers, and cymbalin vines run ten, twelve, and even fifteen feet before any fruit appeared, and that others would

have fruit before they run half that distance, I concluded there was a natural reason for its being so. And in 1819 I took a cucumber and split it lengthwise and sub-divided it into three equal parts across the fruit, and kept the seeds carefully apart, those in the end near the vine, I marked But seeds, and those from the centre, Middle seeds, and those from the end on which the bloom grew, Top seeds, and I planted them separately, in new ground, well manured for the experiment in the spring of 1820; I carefully attended to three hills from seeds of each part of the fruit, divided as stated above, the hills being about twelve feet apart. All of the plants were alike flourishing; the vines from the But seeds ran from eight to ten feet before any fruit appeared, and these were small, with a neck; the vines from the Middle seeds ran from four to six feet before fruit appeared; the fruit was better and without a neck and four fold; the vines from the Top seeds produced fruit large, fine and in abundance, and the first fruit was on the third joint of the vine from the surface of the ground.

I have continued to save seeds from the top or bloom end, and now have cucumbers on the first and second joint, &c. I have been endeavouring to make the experiment on all kinds of vine fruit; corn and peas likewise, but the cut worms have in a great measure, disappointed me; notwithstanding this I have succeeded so far as to satisfy myself that real advantages may be gained by making such selections of seeds. I would have given the above account last year, but I wished to carry the experiment completely through a variety of kinds, &c. If it is new, or you consider it worthy attention, you are at liberty to give it an insertion in your paper.

I am yours with esteem,

SAMUEL GARRISON.

THE FARMER.

BOSTON:—SATURDAY, NOV. 30, 1822.

NEW SYSTEM OF SHOEING HORSES.

We have lately perused with much satisfaction a treatise, entitled "*New System of Shoeing Horses, abridged from the Works of Joseph Goodwin, Veterinary Surgeon to His Majesty George IV. and Member of the Royal College of Surgeons. Containing a Comparison between the English and French methods, and Observations on the Diseases of the Feet, connected with Shoeing. To which are added Observations on Bleeding and the Pulse; a concise View of the Anatomy of the Foot, Notes, Remarks, &c. By JOHN B. BROWN, M.D. M.M.S.S.*" Ornamented with cuts. Boston: Wells & Lilly; 12 mo. pp. 340.

We do not pretend to be greatly versed in the science which is the subject of this little Treatise. We are, however, strongly impressed with the importance of the topics which it discusses, and know that it was originally compiled and abridged by gentlemen who are eminently competent to the tasks they have undertaken.

In France and in England public Schools or Colleges have been founded, patronized by the respective governments, and endowed with ample funds for the purpose of teaching the useful art of Farriery, which in this country is left, we fear, almost exclusively in the hands of men, who are as ignorant of the most important principles of the art, which they pretend to practice, as the unfortunate animals they practice upon. With them every thing is "guess work," and they know

as little of the anatomy of a horse, or the symptoms, character, or correct mode of treating his diseases, as they know about the soil, climate, and productions of one of Herschell's planets. The Veterinary art, notwithstanding its acknowledged importance, seems to be considered as an art for which no apprenticeship, and a science for which no study is requisite. Those who profess any knowledge of the diseases of domestic animals, for the most part, either pretend to know what they do not know, and are therefore a dangerous species of impostors, or their knowledge must have been born with them, (since they have had no chance to acquire it) Mr. Locke's notions relative to innate ideas, the contrary notwithstanding. Indeed it cannot be expected that the professors of any art will make a great acquisitions in the science appropriate to the vocation if the art itself is held in disrepute, and professors are ranked, by virtue of their calling, in the lowest caste of the human species. People who are not respected are not apt to make themselves respectable, and as long as a horse-doctor and a cow-doctor are considered as terms of reproach, and an acquaintance with the diseases of domestic animals, as degrading the character of a biped, who aspires to be one of the "lords of creation," we must expect that ignorance, temerity and cruelty will predominate in one of the most important departments of Domestic and Rural Economy. Physicians, till within a few years, appear to have thought that a knowledge of the diseases of horses and cattle was an attribute, which degraded its possessor; and as Pope says in substance,

"Not to know such trifles is a praise."

The two-legged "creatures" to whom the management, in sickness or health, of four-legged creatures was exclusively committed, never appeared to be impressed with the truth of another assertion of the same poet,

"Act well your part, there all the honor lies;"

but, on the contrary, they viewed their part as a mere one, and of course it was no matter how badly it was acted.

In France and Great Britain, more correct ideas of this subject have been for some time prevalent. Gentlemen in those countries are not ashamed to be useful and useful men in the Veterinary art, as well as other arts, are considered as great men. In France the knowledge of the diseases of domestic animals has long been taught in public schools, patronized and supported by government. In England, near the close of the last century, a Veterinary College was founded under the auspices of some of the most distinguished and public spirited characters. In this institution the whole art of medicine and surgery, so far as they relate to horses, &c. together with the true principles of shoeing and treating horses, while in a state of disease and of health, was, and we believe is still, publicly taught by a surgeon, who had made them his study, and who has the designation of Professor of the Veterinary Art. The Duke of Northumberland was President of this College, and among the Vice Presidents were the Earls of Grosvenor, Morton, Oxford and Rivers; Sir George Baker, Sir T. C. Bunbury, Sir William Fordyce, and the celebrated John Hunter, Esq. Pancras was fixed upon as the site of this College, on account of its vicinity to London. A handsome sum was allowed by Parliament, annually, for the support of this Institution. Mr. Coleman, who has been highly celebrated for his skill and veterinary science, was one of its Professors; and if we mistake not, the author of the book from which the subject of this notice is abridged, is now one of the Professors of this College. The advantages, therefore, of the author of the English edition of

is work were as great, probably, as any part of the world can afford; and that they have been faithfully improved may be presumed from the responsibility attached to his situation, and the talents which alone could have recommended to an office, that could neither be hereditary, purchased by money, nor held as a security. We have no doubt but Dr. Brown has faithfully abridged the original work, and by so doing is entitled to the gratitude of every person in the community who either owns or ever has occasion for the services of the valuable animal of which it treats. But, we said before, we do not pretend to be conversant with the art or science which form the subject of the work we are presuming to notice, and shall therefore conclude this article by appending thereto the Preface of Dr. Brown, which explains the objects of the publication, and, we think, cannot leave a doubt of its utility in the mind of any intelligent reader.

"The Editor of this abridgment, has no other object in its publication, than to meliorate the condition of a very useful animal, the Horse, by presenting to the American public Mr. Goodwin's New System of shoeing. Mr. G.'s original work upon this subject is expensive; and if republished in this country, probably would not be generally read by those who might most benefit by it. It has therefore been thought advisable to abridge it. In this abridgment the editor is careful to select every thing, necessary to the mechanic, a full and practical knowledge of Mr. Goodwin's principles and method of shoeing. It is believed that it contains information, which will compensate any one who feels an interest in the case, for a careful and attentive perusal.

"A circumstance very favorable to the adoption of this new system of shoeing, is that there can be no danger of injury to the foot, from the change, if the shoe be properly put on, however long the horse may have been shod according to the method usually adopted in this country. The principal alteration necessary to be made in the form of the hoof is, at the toes, which usually thick, and not very likely to be injured by one tolerably acquainted with the anatomy of the parts. A bad workman may bring disgrace upon any system of shoeing, or any other mechanical operation, however good it may be in itself, when properly executed.

"The editor of this abridgment does not take upon himself the responsibility of recommending Mr. Goodwin's system of shoeing horses, nor will he feel himself any degree implicated in its success. He presents to the public, as it is, and the public will judge and determine whether it be an improvement upon our present method of shoeing, or not. If no attempt be made to improve, certainly no improvement can be expected. Whatever the opinion of the reader may be with regard to the particular method of shoeing recommended by the author, it is believed that he will find the work well fitted to contain much useful information, relative to the subject on which it treats; and it is hoped that its publication, here, will serve a useful purpose."

MAGNESIAN LIMESTONE.

A writer, who has published several essays in the *National Aegis*, at Worcester, which we have republished, remarks, (see page 140,) that lime "in the state of Carbonate, is found in the Northern part of Worcester county. When employed as a cement it is not inferior to the lime of any other section. As yet it has not been used as a manure long enough to test its properties. From the quantity of Magnesia with which it is mixed, its success on some soils would be doubtful." We are glad to see the attention of that writer turned to the subject of Mineralogy, as connected with Agriculture, and cheerfully contribute our mite of information to promote the object of his essays.

Magnesian limestone has generally been supposed to be hurtful to vegetation, but we believe that when it is proved injurious, it has been in consequence of its being used to excess, or in its hot or caustic state. Magnesia when combined with carbonic acid gas,

seems not to be prejudicial to vegetation, and in some rich in manure, it is speedily supplied with this principle from the decomposition of the manure. Under common circumstances the lime from Magnesian limestone is used in moderate quantities upon fertile soils in Leicestershire, Derbyshire, and Yorkshire, with good effect; and it may be applied in greater quantities to soils containing very large proportions of vegetable matter."

"Amongst some specimens of limestone which Lord Somerville put into my hands, two marked as peculiarly good proved to be magnesian limestones. And lime made from the Breckon limestone is used in Leicestershire, where it is called hot lime; and I have been informed by farmers in the neighborhood of the quarry that they employed it advantageously in small quantities, seldom more than 25 or 30 bushels to the acre. And that they find it may be used with good effect in larger quantities, upon rich land.

"A minute chemical consideration of this question will lead to its solution.

"Magnesia has a much weaker attraction for carbonic acid than lime, and will remain in the state of caustic, or calcined magnesia for many months, though exposed to the air. And as long as any caustic lime remains, the magnesia cannot be combined with carbonic acid, for lime instantly attracts carbonic acid from magnesia.

"When Magnesian limestone is burnt, the Magnesia is deprived of carbonic acid much sooner than the lime; and if there is not much vegetable or animal matter in the soil, to supply by its decomposition carbonic acid, the Magnesia will remain for a long time in the caustic state; and in this state acts as a poison to vegetables. One of the most fertile parts of Cornwall, the Lizard, is a district in which the soil contains mild Magnesian earth."—*Davy's Agricultural Chemistry.*

Quere. How would it answer to pulverize Magnesian limestone without burning, like Plaster of Paris and apply it in the proportion of from 20 to 30 bushels to an acre? In Scotland, pounded limestone is used for manure.

FARMER SUMMARY OF FOREIGN AND DOMESTIC EVENTS.

Success of the Greeks.—An article published in Paris, Oct. 12, states that shortly after a signal defeat of the Turks, they (the Turks) suddenly re-appeared at the foot of the Souli Mountains with 15,000 men. The situation of the Greeks was then very precarious, and it was resolved to destroy their wives and children to prevent their falling into the hands of the enemy, and then rush upon them, and sell their lives as dearly as possible. This resolution reached the ears of the Greek women, but they had influence to prevent its execution, and succeeded in restoring confidence amongst them. It was then resolved that the women, (who insisted upon it) should arm, and 800 were selected and armed. The men amounted to 3000. After invoking the Deity in their favour, they attacked the enemy, the women vying with the men in feats of personal valour, and drove them far from Souli. The result of the action has been 1350 prisoners and four pieces of cannon. The loss of the Greeks was 167 men, and 17 women.

The Great Congress of European Powers was expected to meet at Verona on the 18th of October.

A great earthquake has taken place at Aleppo, in Syria, which buried from 25 to 30,000 of the inhabitants and destroyed more than 20,000 houses.

A war exists between the Turks and the Persians, and the latter have lately gained considerable advantages over the former. Selim Pacha, with 15,000 men, has deserted from the Turks to the Persians.

An instrument for ascertaining the longitude has been invented by a Mr. Harky, in Scotland, which it is said by competent judges will completely answer the purpose on land or at sea in calm weather. The reward for the discovery of a complete instrument for ascertaining the longitude is 20,000 pounds.

A London paper states that Mr. Canning's principles are more liberal than those of the late Marquis of Londonderry; and that there is reason to believe him to be so well inclined to the Greek cause that he will undertake something in its favour.

The story lately republished from the London Globe respecting a great secret discovered in the art of tanning, for which the inventor had received a large sum of money, turns out to be fabulous.

Dodart, in a communication to the Royal Academy of Sciences at Paris, computed that an elm, every year, at a medium, produces 230,000 seeds; and therefore supposing it to live 110 years, 23 millions of seeds during its whole age. Fern is far more fertile in seeds. Harts-tongue produces in a year a million of seeds. These seeds must have a use beyond continuing their species.

Since the discovery of the New-World, our English gardens have produced 2345 varieties of trees and plants from America, and upwards of 1700 from the Cape of Good Hope, in addition to many thousands which have been bro't from China, the East Indies, New-Holland, various parts of Africa, Asia, and Europe; until the list of plants now cultivated in this country exceeds 120,000 varieties.—*London paper.*

The Annual Meeting of the Plymouth Agricultural Society was held at Plymouth, on the 20th of November, inst. Daniel Howard, Esq. was chosen President, and Rev. Morril Allen, and Abiel Washburn, Esq. Vice Presidents. The premiums awarded were to Samuel A. Turner of Scituate, for compost manure \$15—Col. B. Murdock of Warrham, for the best crop of hay \$10—William Jackson, Esq. of Plymouth, for the best crop of wheat \$10—Leonard Hill of Bridgewater, for the best crop of oats \$8, and for the best crop of potatoes \$7—Solomon Alden of Bridgewater, best crop of corn \$10—Alpheus Forbes of Bridgewater, 2d premium for compost manure \$10—Jacob Thompson of Middleborough, for the best six lambs \$5.

In Virginia a two year old heifer has a calf six weeks old which weighs 135 lbs.

Cotton, of a quality in no way inferior to that which is brought from the South has been raised this year at Oyster bay, L. I.

The Baltimore Morning Chronicle of November 16th, says "it would not be much too early to hear the sleigh bells enlivening our streets, and yet so extraordinary is the season, that we yesterday saw ripe Cherries that were plucked from a tree in this city."

Fuller's Earth.—The Mobile Alabama Register mentions that Fuller's earth had been discovered in that vicinity of a superior quality, and such as will answer every purpose to which that substance is usually applied.

A quarry of marble, of a most beautiful and delicate grain, and said to be equal to the Italian has lately been discovered in Lancaster County, Penn.

A meeting was held at New-York, on the 15th inst. to form a Woollen Manufacturers' Society. This society proposes to give premiums for the best specimens, and to establish regular Fairs in the city, for the exhibition and sale of woollen fabrics.

A Patent Bedstead is advertised in New-York, which may be taken down or set up in one minute, without the use of tools, and does not contain the least harbor for bugs or dirt.

The Court House in Northampton was destroyed by fire on the 20th inst.

Spontaneous Combustion.—Within a month past there have been three instances of spontaneous combustion in large masses of coal in our Navy Yards—at this place, at New-York, and Portsmouth, New-Hampshire, by which each has been in great danger of being destroyed. This coal was obtained from one of the mines near Richmond; was found to contain an unusual quantity of sulphur; lay exposed to the air and rain; and became ignited near the centre of the heaps. It would be well for persons having large quantities of the coal on hand, to examine it frequently, and it would be a subject worthy the attention of the curious and philosopher, to explain the cause of this ignition.—*Nat. Hist.*

A plan is projected to unite the waters of Lake Ontario, with Lake Champlain, by a Canal, across the country from Ogdensburg to Plattsburg.

A new Map of Vermont, from actual survey, by James Whitelaw, Esq. is published with high recommendations.

FOR THE NEW ENGLAND FARMER.

We hope the following sketch from an English poem of the miseries endured by the noble animal whose sufferings are so well described, may a tendency to direct the attention of those who avail themselves of his services to his wants, and induce them to remember that "the merciful man is merciful to his beast."

Short-sighted Dobbin!—thou canst only see
The trivial hardships that encompass thee:
Thy chains were freedom, and thy toils repose,
Could the poor post-horse tell thee all his woes;
Shew thee his bleeding shoulders, and unfold
The dreadful anguish he endures for gold:
Hid'd at each call of business, lust, or rage,
That prompt the traveller on from stage to stage,
Still on his strength depends their boasted speed;
For them his limbs grow weak, his bare ribs bleed;
And though he groaning quickens at command,
Their extra shilling in the rider's hand
Becomes his bitter scourge;—'tis he must feel
The double efforts of the lash and steel;
Till when, up hill, the destin'd inn he gains,
And trembling under complicated pains,
Prone from his nostrils, darting on the ground,
His breath emitted floats in clouds around:
Drops chase each other down his chest and sides,
And spatter'd mud his native colour hides:
Through his swollen veins the boiling torrent flows,
And every nerve a separate torture knows.
His harness loos'd, he welcomes eager-eyed
The pail's full draught that quivers by his side;
And joys to see the well-known stable door,
As the starv'd mariner the friendly shore.

Ah, well for him if here his sufferings cease'd,
And ample hours of rest his pains appeas'd!
But rous'd again, and sternly bade to rise,
And shake refreshing slumber from his eyes,
Tire his exhausted spirits can return,
Or through his frame reviving ardour burn,
Come forth he must, though limping, maim'd and sore;
He bears the whip; the chaise is at the door.—
The collar tightens, and again he feels
His half-heal'd wounds inflam'd; again the wheels
With tiresome sameness in his ears resound,
O'er blinding dust, or miles of flinty ground.
Thus nightly robb'd, and injur'd day by day,
His piece-meal murderers wear his life away.

FOR THE NEW ENGLAND FARMER.

The person who tells a falsehood, in order to conceal a weak or wicked action, leans upon a broken reed which not only does not sustain him, but threatens every moment to break and pierce his hand.

Innocence and mystery never inhabit long together; and the first step towards vice is to make a secret of actions which are neither vicious nor unbecoming.

A man does well to take advice, but if he is always governed by his advisers he loses his own free agency. Advice is useful to enlighten the understanding, but ought not to direct the will against the dictates of the judgment.

We can forgive those who hate us, and even those who treat us with contempt may be forgiven, but can scarcely be loved. Affection can never blossom, if its bud has been blighted by scorn; or in other words we cannot love those, who make it evident that they despise, or think meanly of us.

Attention to the wants and wishes of those around us, even in matters of small importance, but frequent occurrence, gives the greatest charm to social intercourse.

From the Essex Register.

Mr. Palfray—As it may be interesting to some of your readers, to learn the results of the experiments of some of the most enterprising Agriculturists in the County. I have made an abstract of the Report of the Committee to examine the claims for premiums "on Indian Corn and other crops," and if agreeable to you, should be pleased to have it published. Such evidence was required by the Committee, as leaves no doubt of the accuracy of the statements.

Respectfully, yours,

JOHN W. PROCTOR.

Danvers, Nov. 21, 1822.

Mr. Daniel Burnham, of Newburyport, raised on one acre 117 1-4 bushels of Indian corn, weighing 50 lbs. to the bushel. The seed came from the upper part of the Missouri Territory. At present it is uncertain whether this kind of corn can be cultivated to advantage in common seasons.

Mr. John Lees, of Newbury, raised on one acre 103 bushels and 20 quarts of Indian Corn, weighing 51 lbs. to the bushel, 18 bushels of turnips, 1750 lbs. of pumpkins, 150 lbs. squashes—estimated equal to 118 bushels of corn to the acre.

Mr. Henry Little, of Newbury, raised on one acre 116 bushels and 9 quarts of Indian Corn, weighing 52 lbs. to the bushel.

Mr. Erastus Ware, of Salem, raised on one acre 93 3-4 bushels of Indian Corn.

Mr. Richard Crowninshield, of Danvers, raised on one acre 90 1-2 bushels of Indian Corn.

Mr. Daniel Mears, on the farm of the Hon. William Reed, of Marblehead, raised on one acre 87 1-2 bushels of Indian Corn.

Mr. Jacob Gould, of Boxford, raised on one acre 72 bushels of Indian Corn.

Mr. Isaac Dodge, of Hamilton, raised on one acre 70 3-4 bushels and 5 quarts of Indian Corn.

Mr. Jacob Wilkins, on the farm of Benj. T. Reed, Esq. of Marblehead, raised 50 bushels of Barley to the acre.

Mr. Henry Little, of Newbury, raised 687 1-2 bushels of English Turnips on one acre.

Messrs. *Silas and Joseph Little*, of Newbury, raised 615 bushels of English Turnips on one acre.

Mr. John Dwinel, of Salem, raised on 101 1-3 rods of land, 29 tons, one quarter, and 25 lbs. of Beets.

Mr. Dwinel also raised 8 tons and 3 cwt. of Carrots, on 111 1-2 rods of land.

Mr. David Little, of Newbury raised on one acre 970 1-2 bushels of Mangel Wurtzel, 2 bushels of Carrots, and 107 Cabbages.

The crops of Potatoes and Ruta Baga were not large.

From the New-York American.

The Battle of the Beets.—By this morning's mail, we find the papers from all quarters challenging the world to vie with the mammoth vegetables they respectively describe. These challenges, to say the least of them, are very harmless; and, as there is no probability that the contest will be settled by powder and ball, we feel little anxiety about being involved in the contest, as *participes criminis*, by republishing their notes of defiance.

And first from Ohio—the land of milk and honey. The Sandusky Clarion states that Ma-

jor Frederick Falley has this season raised a Beet, from the seed of the *Bonaparte Sugar Beet*, which, after trimming off the leaves weighed *thirty pounds*. It measured in length three feet and four inches, in circumference two feet and seven inches.

Next comes our own state, through the medium of the *Saratoga Sentinel*, the editor of which has possession of a large red Beet, raised in the garden of the Hon. Samuel Young, the present season, which measures two feet four and a half inches in circumference, and weighed, when taken from the ground, *eighteen pounds*.

And now, "Pennsylvania against the world" The Westmoreland Republican announces the satisfaction of having seen one which measured twenty-two inches and an half, and another twenty-three inches and three-fourths in circumference.

The Philadelphia Union also publishes an account of a "gigantic vegetable"—a beet, which grew in the garden of Mr. D. Kramer, which weighs *fifteen pounds and a half*, and measured at the thickest part thirty-four inches, and somewhat lower down twenty-seven inches. The Editor triumphantly asks, "*Who can beat this*." We refer him to the foregoing statements, and especially to the account in the Sandusky Clarion, which it must be admitted has sounded pretty loud on this occasion.

IMPORTANT INVENTION.

A gentleman of this State, to whom this country is much indebted for his former invention has lately completed a Machine for *Cutting Fur from Skins*, without injury to the Pelt, which hitherto have been rendered useless for leather. It is also ascertained, that this machine will shear cloth much better than any machine now in use. One man can cut, with this Machine, the fur from 1000 skins per day, or shear 2500 yards of cloth—whereas the cutting of the fur from 100 skins or shearing 120 yards of cloth is considered a day's work, by the present mode of cutting and shearing. Thus there is a saving of 19-20ths of the labour—the fur cut by this machine is pronounced, by good judges, to be better than that cut in the usual way.—Considering the great saving of skins, (particularly the seal,) and labor, we must pronounce it one of the most important inventions which has honored our country.

Palladium.

Hogs.—An Ohio farmer recommends coal, as useful in fattening hogs. After giving his hogs small quantity daily, say two pieces to each about the size of a hen's egg, they discontinued rooting, were more quiet, and appeared to fatten faster. He omitted the coal a few days at they commenced rooting; he gave it again at they ceased to root. He supposes that the coal corrects that morbid fluid in the stomach which incites them to root deep in search of fresh earth.

LARGE TURNIPS.

To the many extraordinary instances of the strength and fertility of our soil, we take pleasure to add, that William Ladd, Esq. of Minot, in this county, has raised on his farm, this year turnips of unusual size. He stated to us last week, that he weighed *three* of them, and their joint weight was *sixty pounds*! Beat this when can.—*Portland Gazette*.

NEW ENGLAND FARMER.

No. 19.

From the American Farmer.

FRUIT TREES.

Edgefield, South Carolina, Feb. 23, 1822.

"On Savage stocks insisted learn to bear."

There are few subjects more deserving the attention of the American agriculturist than the art of grafting, and few which are more unaccountably neglected. Not only to natural philosophers, but to whomsoever the works of naturalists can impart a charm; it must be pleasing to know something of that affinity in the saps of different trees, which qualifies one to bear the fruits of many, however widely differing in shape, size, and flavor. Thus every variety of plum, peach, nectarine, apricot, and almond will succeed well on the wild plum stock. The apple, pear, quince, medlar, service, and hawthorn, though differing with one another, will all agree to grow on the hawthorn, (*cratægeus*). The whole of the *Icosandria* class appears to discover a disposition to graft on each other. It seems somewhat derogatory to the character of American husbandry, that the third volume of the Farmer is nearly completed, and nothing like a lecture has yet appeared, upon an art, so productive of profit and pleasure. However desirable, I do not presume on the present occasion, to supply the deficiency here complained of. The very short time since my attention has been directed to the subject, forbids it; but my zeal in the cause, prompts me to begin, what I hope to see completed by an abler hand. Faith and philosophy appear to agree in the simplicity of the origin of all things.* From these premises we might conclude, that previous to all changes by accident or culture, all the fruits of the earth might have flourished on one parent stock! Culture seems to have full as much influence as difference of genus. As the apple and pear, apple and quince, cherry and plum, and even the wild and tame cherry, will not graft together, although of the same genus; while the apple and hawthorn, peach and rose will succeed together by grafting.† And I have been informed by practical grafters, that many varieties of cultivated apples refuse to grow on the wild crab stock. Phillip Miller speaks of the wild cherry as a stock for the tame, but there must be a difference between his variety and that of this country; or a further change has taken place since his time, as I can assert from repeated trials, both by budding and grafting, that an union cannot be effected. And if there be not more of poetry than truth in Virgil, many trees which claimed kin when he wrote, disown it now. According to this view of the matter, in the ratio that the different genera of trees recede from their original condition, will be the difficulty of uniting them by art. Thus, though the cultivated apple and pear will not graft together, perhaps the wild apple and stone pear might; scientific gentlemen who have the opportunity, owe it to philosophy to make the experiment. There is something sublime in the

idea, that the first cause should have left the fruits of the earth in their crude state, to be mellowed by the hand of man; that in effecting this salutary change, the conceit of his skill, by inciting exertion, should expel his inborn apathy so fatal to his happiness and glory. All the instructions I have ever seen on grafting, I know to be very imperfect. The old bungling method of applying three or four pounds of clay and stone-horse dung to the grafts, should have been long ago exploded.* The sole intention of a wrapper being to exclude the air from the wounds occasioned by the process, a cerate will answer the purpose far better, cheaper and neater; a piece of the size of a hazel nut being generally sufficient. And after the grafts have made some little progress in uniting with the stocks, the wax may be collected for future operations.

Almost every publication which I have had the opportunity to peruse, directs one third of turpentine in the composition of a grafting wax; this though very ductile and pleasant to use, I found certainly to destroy both grafts and stocks, as far as the wax came in contact with them. From the numerous respectable authorities recommending this wax, I was very liberal in its application to a number of choice grafts, without suspicion; but had the vexation upon the first inspection by removing the wax, to discover that a complete mortification had taken place under the wax; and even extending further in little lines along the grain of the wood. I separated the dead wood, and with a more friendly cerate, regrafted the surviving buds with success. Whatever may be the innocence of a wax containing one third turpentine in a northern climate, I was so well convinced from my trials of its deleterious effects in Carolina, as to reject it entirely. After many experiments to ascertain the best composition for a grafting wax, I prefer the following:—One measure of olive oil or hog's lard, 3 do. of melted bee's wax; mix well while hot, to be worked after it is cool, till sufficiently pliant. Perhaps sweet gum resin might form the basis of a more ductile wax, without imparting a destructive quality.—The following general rule may be observed by the novice in the science of grafting. All trees of the same genus, (not greatly altered by art,) will succeed together by inoculation. Those who have the opportunity and inclination to indulge in speculations on the production of vegetable hybrids† should try trees of the same class and order, or if differing in this particular, such as discover a similarity in the fruit, leaf, or sensible properties of the sap and wood, &c. Grafting is performed by making an operation upon

the wood of the stock, to which is attached the cut of a twig from another tree, both wood and bark, with an indefinite number of buds.* Tho' March and April are the usual months for grafting, it may be protracted till May, and even June, perhaps with better success than earlier; by keeping the grafts in a degree of moisture which will just prevent their withering. The stocks should not exceed the size of a large goose-quill, but if they are old, select limbs of the same size; if there be none, head down the stock and wait till they come; the grafts will be more neat and valuable for the delay. The twigs should be selected from a young healthy tree, and to be as nearly as possible of the same size with their stocks. They should be cut before the buds have begun to swell.

No other instrument is required than a sharp knife, with sufficient strength to perform the operation; a warm moist day should be preferred. Cut the stock even and smooth, split about half an inch with the knife, cut off a bit of the twig to be grafted, with one or two buds, wedge shaped, having one edge thicker than the other, fit very exactly the edges of the wood on the thick side. Then cover as much of the graft and stock as was wounded in the operation, with as much grafting wax as will exclude the air. There are other methods of grafting in the wood, but the method here laid down being the most simple and certain of success, I think it useless to describe any other. But the season of grafting is somewhat short and precious, while that of budding is lasting and very certain. Moreover, many trees will bud perfectly well, which will not graft at all; as the mulberry, &c. Budding or inoculation is the very simple art of ingrafting one tree on another; by making an incision through the bark only of the stock, sufficient to make bare a small surface of the wood; while a little strip of bark containing a single bud of a size corresponding with the incision made on the stock, is fitted exactly and speedily on the spot of wood deprived of its original bark. Although midsummer is the usual time allotted for budding, it may be performed with success from the first of May, till the last of September, or even later. I think I have succeeded better in September than any month with such buds as had a sufficiency of sap to peal freely. And to insure success, I will here remark, that both grafts and stocks should at all times abound with sap. For early budding select a shoot of the preceding year's growth; but if deferred to the time usually prescribed, (say midsummer) take the best grown shoot of the same year (with good prominent buds,) something larger than the size recommended for grafting. Cut out a little billet of wood about an inch long, having the bud in the middle; now having placed it on the stock intended to receive it, mark the bark thereof with the knife at each end; thus,  for the more precise fitting of the strip of bark to be introduced.

* See Owen's Arts and Sciences, Miller's Gardener's Dictionary, &c. &c.

† A vegetable hybrid or mule, is more expeditiously produced by grafting different genera than by introducing to each other, the blooms of the different sexes. It is a fact in vegetable, as well as animal physiology, that all mules are not barren. Thus the peach grafted to the rose, though in appearance a complete peach tree, bears roses only; nor can it be regrafted to either peach or rose. But the apple on the hawthorn, is as capable of bearing fruit and regrafting as any other apple tree.

* See the writings of Moses, Linneus, Darwin, &c. &c.

† There is considerable difficulty in uniting the peach to the rose; but when done, the growth is as luxuriant and perhaps more hardy than from its own root.

* I inserted some apple grafts about the middle of last November, the wounds have partially healed, and as far to do well as spring grafts—grafting may be commenced as soon as the buds begin to swell in spring.

ced; then make an incision quite through the bark without materially injuring the wood.— Thus I now raise the bark with the thumb nail or point of the knife, and instantly apply the bark containing the bud, which may be conveniently separated from its wood by the thumb nail or point of the knife. Perhaps the operation will find it more convenient to cut out the billet opposite to the chosen bud. Thus the twig will now serve as a kind of handle to turn off the bud with more despatch and safety. But whatever method may be chosen for separating the bud, no time should be lost after having it adjusted, till it be close tied on with a woollen string, sufficiently strong for the purpose. Observing to wrap above and below the bud neatly, without compressing the bud itself. The strings should be smeared with grafting wax, which will make them better to tie, exclude the air, and remain sound for future operations. An evening or moist day should be preferred for this method of grafting also. One week is sufficient for the strings to remain, for if the buds have not effected their union in that time, they never will. If they do not appear withered at the time of removing the strings or shortly thereafter, it may fairly be presumed they will live; but if withered, the stocks may be forthwith rebudded. All the writers I have read on budding, state that the buds do not put out till the succeeding year! until Mr. Andrew Knight recommended the forcing of them by a strong ligature above the inserted buds, with the intent to check the flow of sap by them; but afterwards removes the ligatures, lest they have too much sap. This appears to me like watering a plant till it has a good start, and then withdrawing our care. After Mr. Knight has been at the trouble to remove his ligatures, he will find his initiated buds again checked, if not starved by the older branches drawing the sap from them. My method of forcing I deem to be far more simple: so soon as I ascertain my buds will live, which may be known in about a week, if the stock be small I instantly head it down, with one stroke of my knife, immediately above the bud I wish to nourish. If the stock be large, I amputate the principal branches; the consequence is an immediate bursting of all the latent buds, together with the inoculated. As the ingrafted branches multiply, I diminish the number of the original ones, till nothing remains but the new tree; nor will it be long, till *"ingens erit ad cultum; raris felicibus arbus, Miraturque novae, frondes, et non sua poma."**

From this simple treatment, my buds will extend if inserted early, many feet, with numerous branches the same summer, and be prepared to produce a crop of fruit the ensuing year; nay, more strange to tell, the same year in some instances. Let the theorising orchardist who is fearful of a summer pruning, (because his books or father's have not told him of it,) recollect what is the consequence of breaking a riding switch, or half the boughs of a tree being torn off by weight of fruit, or other accident.— Whether is death the result, or a sudden produc-

tion of numerous thriving shoots, in some cases gay flowers? By the by, I think the growing season the proper time for pruning, and practise it accordingly. But whatever may be the principles of vegetable life, the buds of trees may be thus safely forced, and if they are not at some time, or other forced in the way here recommended, they will either never put out, or will put out only to starve; and the sooner they are thus pushed the better.

Rees's Encyclopedia objects to the buds extending the same year in which they are inserted, on the ground that they will prove too tender to resist the shock of winter; but these fears I can assert to be groundless; the last severe spring put this matter fully to the test with me; I had the buds of apricots, almonds, white walnuts, &c. in both states many which had not put forth, were completely destroyed, while those which had made progress resisted the storm.

The persimmon, (*Diosperos Virginiana*) and walnut, &c. will receive a tarnish on the surface of the wood, in a few seconds after the bark is separated from it. This is a chemical change in the sap, caused by its coming in contact with the air, which perhaps may defeat the operation and account for failures, and for the general opinion that these trees will not succeed at all.* But to insure success the operator must use the greatest dexterity; having cut through the bark of the stock as before directed, separate the bark containing the bud to be introduced; this done, keep it close pressed (without being moved from its wood) with the thumb and finger of one hand, while the bark is raised from the stock, with the other, having the string in readiness, apply the bud and confine it according to art. Perhaps there is no tree more difficult to bud than the Persimmon; but choice kinds may be sufficiently well propagated in this way. When budding the hickorynut, persimmon, chestnut, &c. grafting wax should be applied to the bud before it is confined with the string, and as much as squeezes out between the wrappings of the string, should be pressed down with the finger or thumb, so as effectually to exclude the air; which will make the operation more sure and prevent the depredation of small worms, which are liable to infest such trees under the inserted bark. This method of waxing should also be applied to the walnut and other difficult trees. The pecan (*Carya Olivaformis*) did not appear to take so well as the walnut, but my trials were made rather late in the season. I

* Rees's Encyclopedia says, the mulberry, fig, and walnut, will only ingraft by inarching; and Philip Miller, a very celebrated English gardener, says the apple will ingraft on none, but its own stock; but these are the mistakes of great men. I don't believe there is any tree that will bud more successfully than the mulberry; the walnut tolerably well, and from the few trials I made with the fig, I am induced to think there may be no difficulty with that. I budded some mulberry buds on the 11th of June, and by the 29th of August I measured one upwards of a foot in length, with ripe fruit.

Mr. Robert Lofton, living a few miles from Edgefield Court House, has ingrafted apple trees which he says have flourished upwards of 20 years upon a variety of indigenous hawthorn. I have been informed of another instance in the same district; and I have myself very luxuriant grafts on the parsley leaved hawthorn, which produced apples large, delicious and uncommonly sound. The most prolific source of ignorance and oppression is that of suffering great men to think for us. Crippled indeed would be the operations of nature were they controlled by the theories and conceits of the wisest man.

succeeded very well in budding the chestnut (*castanea esculenta*) to the dwarf chestnut or chinquepin (*Castanea Pumila*.) but from a neglect of a timely waxing had them destroyed by worms. It seems to be a prevalent opinion, that buds cannot be separated for any length of time, from the parent tree without ceasing to vegetate. I kept some cuts of the almond, peach and apricot, nearly a month in moist earth, and budded them with success. They may conveniently be preserved for a few day's journey, in wet cloth.— But unnecessary delays should, of course, be avoided. The art of budding and grafting, is particularly important in this country, where we have at command such a variety of hardy native stocks, and surplus land to devote to trees. The persimmon bears a fruit replete with sugar, which is never injured by the frosts, resists rot perhaps better than any other fruit; is a very great bearer, and will flourish without cultivation, on the poorest soils, whether of sand or clay, wet or dry. The wild plum will also grow on very poor land, and is durable; but grows too slow in general for a nursery stock: it should have attained a sufficient size previous to grafting (say three or four inches in diameter) to keep pace with the rapid growth of the peach and some plums—remembering always to insert the buds or grafts, as close as possible to the trunk, or a large limb. Under these circumstances the wild plum will be found an excellent stock for an extensive tribe of delicious fruits. The same remarks will apply to the elegant parsley leaved hawthorn when used as a stock for the apple, pear, &c.; another advantage this stock (hawthorn) also has of the apple and most of the other hawthorns, it is very hardy, little choice of soils, and is never plagued with moss, as it sheds its old bark annually.— Gentlemen, whose land abounds with these hardy native stocks (instead of considering them a nuisance,) might, by selecting the hardiest and richest fruits for grafting, with a small portion of time and expense, have a profusion of them highly important to man and beast.*

I hope the readers of the Farmer will not be illiberal in communicating the result of their enquiries to the public, to whom they owe a debt, for reading your paper, which can only be discharged with intellectual coin; and let the miser in knowledge recollect, that it is a dark body indeed, which is always imbibing light without reflecting any. Nor can I dismiss this subject without inviting the attention of the ladies thereto; if the tree of knowledge was forbid them, this book of knowledge is not. Surely to know something of grafting is more worthy of their regard, than many of the transient amusements of fashion. Human fashion, like a Proteus, ever changing; what is taste to-day is ridiculous to-morrow. But, the fashions of Nature are eternal as truth, and bestow blessings with an unsparing hand, on those who search them out! The rose will not only graft and bud well to its genus; but will take on those of a different one, by which the plain fruit tree is converted into an imitable flowering shrub. This art being equally applicable to the propagation of flowering shrubs, as fruit trees, would

* In the spring of 1821, I transplanted some wild plum stocks, from 2 to 3 inches diameter, close pruned, whereon I grafted some peaches, plums, &c. I counted, in the fall of the same year, on a single graft, 220 flower buds.

* Dr. Darwin has given the following translation of this passage:

So shall the trunk with loftier crest ascend,
And wide in air robust arms extend,
Nurse the new buds, admire the leaves unknown,
And blushing bend with fruitage not its own.

T. N. E. Farmer.

add much to the flower garden. Perhaps there is no employ or amusement better calculated to wean the mind from sorrow, than this truly innocent one; and while it affords a present enjoyment, awakens the hope of more in future. After what has been written, shall I attempt an eulogy on an art, which enables us to collect from all quarters of the world (climate not forbidding) the most choice fruits, and plant them on stocks hardy and mature, capable of affording as much fruit in two or three years as the seed would yield in a dozen or more. And who can deny, from our present imperfect knowledge of grafting and the hardy hybrids producible thereby, but that trees, destined to eternal barrenness may be burthened with the produce of the palm, the olive, or the bread fruit tree? We have seen the peach "blossom as the rose;" and with our present knowledge of the principles of ingrafting, it is practicable for every moderate farmer, by devoting to the exercise of this art, the time he is wont to sacrifice to inglorious sloth, or criminal amusement; to create a paradise of fruits and flowers, where thorns and briars now grow but to curse his land.

This communication has spun out to a much greater length than I intended at the commencement; but in the progress I thought, as encyclopedias and dictionaries of arts and sciences, &c. were not accessible to all your readers, it might not be amiss to describe the processes at length. However, if you find fault of the length, you can prune the superfluous shoots, or make any disposition of it you think proper.

I will trespass no further on your patience, than to wish you all the success your zeal has merited.

ABNER LANDRUM.

AGRICULTURAL PROFESSORSHIP.

The Agricultural Society of Albemarle, Virginia, of which Mr. Madison is President, has founded a Professorship of Agriculture, at the University of that State, and voted \$1000 for its support. Mr. Madison has addressed a circular to the presiding officers of different Agricultural Societies, from which, by the kindness of S. W. POMEROY, Esq. Vice President of the Massachusetts Agricultural Society, we have been permitted to publish the following extracts:

Str.—The enclosed Resolutions of the Agricultural Society of Albemarle, explain the wish of the Society to provide for Agriculture the advantage of a Professorship, to be incorporated in the University of Virginia; the means proposed for making the provision; and the hope entertained of a general co-operation in the scheme.

The present seems to be an important crisis in the Agriculture of Virginia. The portions of her soil first brought into cultivation, have, for the most part, been exhausted of its natural fertility, without being repaired by a meliorating system of husbandry; and much of what remains in forest and can be spared from the demands of fuel and other rural wants, will need improvement, on the first introduction of the plough.

These truths are now sufficiently impressed on the public attention; and have led to the establishment of the Agricultural Societies among us, which are so laudably promoting the work of reform.

As a further means of advancing the great object, it has occurred to the Albemarle Society,

that a distinct Professorship in the University of the State, if sanctioned by the proper authority, might be advantageously appropriated to the instruction of such as might attend, in the theory and practice of rural economy, in its several branches.

To the due success of agriculture, as of other arts, theory and practice are both requisite.—They always reflect light on each other. If the former, without the test of the latter, be a vain science; the latter without the enlightening precepts of the former, is generally enslaved to ancient modes, however erroneous, or is at best but too farly and partial in adopting salutary changes. In no instance, perhaps, is habit more unyielding, or irrational practice more prevalent, than among those who cultivate the earth. And this is the more to be lamented, as agriculture is still so far below the attainments to which it may fairly aspire.

A professorship of agriculture might derive special advantage from the lights thrown out from the chair of Chemistry in that Institution. This science is every day penetrating some of the hidden laws of nature, and tracing the useful purposes to which they may be made subservient. Agriculture is a field on which it has already begun to shed its rays, and on which it promises to do much towards unveiling the processes of nature to which the principles of agriculture are related. The professional lectures on chemistry, which are to embrace those principles, could not fail to be auxiliary to a professorship having lessons on agriculture for its essential charge.

The fund contemplated for the support of such a professorship, is to consist of a sum drawn from unexpended subscriptions, from special donations, and from a diffusive contribution not exceeding a dollar from an individual. It is hoped, that for a purpose of such general utility, the number of contributors will more than make up for the smallness of the respective sums; and that with the other resources, means may be gathered not only adequate to the immediate views entertained; but justifying an enlargement of them.

Should this prove to be the case, it will be an improvement of the plan of agricultural instruction, to provide and place under the superintendence of the Professor, a small farm in the vicinity to be cultivated, partly as a pattern farm illustrating practically a system at once profitable and improving, partly as an experimental farm, not only bringing to the test new modes of culture and management, but introducing new plants and animals deemed worthy of experiment. In obtaining these, aid might be found in the patriotic attention of the public and private Naval Commanders, in their visits to foreign countries; and it might well happen that occasional success in rearing new species of varieties, of peculiar value, would yield in seeds and stocks a profit defraying the expenses incurred on this head.

A farm exhibiting an instructive model, observed as it would be by occasional visitors, and understood as it would be in its principles and plans, by students returning to their dispersed homes, would tend to spread sound information on the subject of agriculture, and to cherish that spirit of imitation and emulation which is the source of improvement in every art and enterprise.

Agricultural Society of Albemarle, Oct. 7, 1822

On the motion of Gen. JOHN H. COCKER, the following Preamble and Resolutions, were adopted:—

WHEREAS, the establishment of a Professorship of Agriculture, in one of the principal seminaries of learning in this State, is a measure eminently calculated to hasten and perpetuate the march of agricultural improvement, already so happily commenced; And whereas, there are grounds to believe that such an institution may be incorporated into the University of Virginia, a position at once the most advantageous and convenient to every part of the State: And whereas this Society could not make an appropriation of its funds more conducive to the permanent attainment of the primary objects of its institution—and as it is reasonable to expect that all the Agricultural Societies, the Farmers and Planters generally, will cheerfully contribute to an Establishment of such universal interest.—Therefore

Resolved, That one thousand dollars of the sum, now in the hands of the Treasurer of this Society, be appropriated to the establishment of a Fund, the profits of which shall go to the support of a Professorship of Agriculture at the University of Virginia.

Resolved, For the furtherance of this design, that the President be requested to prepare an address to the other Agricultural Societies of this State, requesting their co-operation in this scheme—and further to promote the same object, and increase the said fund, that a committee be appointed to solicit donations not to exceed one dollar from individuals in every part of this Commonwealth.

Resolved, That the aforesaid appropriation, together with all that may accrue under the foregoing Resolutions, be loaned to individuals on good personal security, or to corporate bodies; and that when the sum loaned to any one individual shall amount to one thousand dollars or upwards, landed security shall be required: That the interest shall be payable semi-annually, and shall be reinvested, until the yearly profits of the Fund shall be sufficient to afford an income equal at least to a Professorship in the University.

Resolved, That the funds above referred to, together with donations of books, and property of any other description, be with the permission of the Legislature transferred to the Rector and Visitors of the University in their corporal capacity. (Extract from the minutes.)

P. MINOR, Sec'y.

From the Philadelphia Democratic Press.

On Tuesday night the audience at the City Theatre were exceedingly amused by the representation of "Modern Honor." The laughter was loud, long and oft repeated; nay sometimes shouts of applause were heard. The use of cologne water to soften the hands, of oak bark to make the skin bullet proof, and the lutestrung dress to render the person invulnerable, were all duly served up with appropriate dialogue and action. The squatting and dodging was performed by Sambo Puffy and Caesar Huffy, valets to Col. Bombastes Puffy and the Hon. Mr. Huffy. The song of "Oh cruel am de Bullet Ball," was encored; the whole piece was well received and was given out for a second representation amidst shouts of applause.

COMMUNICATED FOR THE NEW ENGLAND FARMER.

SUN FLOWER OIL.

It appears from experiments made formerly in this State, that a bushel of Sun-flower seed, yields a gallon of oil, and that an acre of ground planted with the seed three feet apart, will yield between forty and fifty bushels of the seed. This oil is as mild as sweet oil, and is equally agreeable with salads, and as a medicine: It may also be used with advantage in Paints, Varnishes, and Ointments. From its being manufactured in our own country, it may always be procured in a fresh state. The oil is pressed from the seed in the same manner, that cold drawn linseed oil is obtained from flaxseed, and with as little trouble. Sweet oil sells for *six shillings a quart*. Should the oil of the Sun-flower sell for only two thirds of that price, the product of an acre of ground, supposing it to yield only forty bushels of the seed, will be £32,—a sum far beyond the product of an acre of ground, in any sort of grain. The seed is raised with very little trouble, and grows in kind of moderate fertility. It may be gathered and shelled, fit for the extraction of the oil, by women and children.

Various uses of the Helianthus annuus, or common Sun-flower. Translated from a Portuguese work, entitled: Biographia dos alkolia raos, published in 1798 at Lisbon, by Jos. M. Da Corre Jellas.

1. The sprouts are eat with oil and salt.
2. Bread is made from its seeds, and also gruel for children.
3. Some American nations eat the seed.
4. The seed gives oil for several uses.
5. It fattens fowl.
6. Its leaves are an excellent food for cattle in summer, and increases the quantity of milk in cows; they are easily gathered, being of a large size, the inferior are to be first gathered.
7. They are also good for sheep.
8. Its stems can be used to support climbing plants, instead of poles.
9. They serve for fuel. An economist of Frankfort said that it was good as willow wood for this use. He sowed two acres and a quarter, and by that he saved the value of thirty dollars, and had oil worth twenty dollars.
10. Lastly, they furnish excellent ashes. The seeds when roasted have the flavour of coffee, and the infusion of them in the manner of tea, is a pleasant beverage.

From the New York Evening Post.

We lately saw in the English papers, an account of a marvellous discovery in the art of tanning. It is stated in the London Globe that the discoverer sold his secret to a member of parliament for 10,000*l.* in hand, 5,000*l.* on the first of January, 5,000*l.* per annum for four years next succeeding, and afterwards, 11,000*l.* a year for life. The following articles from the Liverpool Mercury, however, contains a satisfactory disposal of it.

LEATHER TRADE.

To the Editors of the Liverpool Mercury:

Gentlemen,—I lately observed a paragraph in your independent paper, announcing that a discovery had lately been made “to tan leather in six weeks that usually requires twelve months, at less than half the expense.”

The moment I read it, I declared it must be a fable; but, for curiosity's sake, I was resolved to trace it, if possible, to its source. This I have done, and find it quite as fabulous as I thought, though I must do the authors, (who are

respectable, and treated me with every civility,) the justice to acquit them of all wilful misrepresentations: but I have since every reason to believe that the rumours in question alluded to our manufactory at Dorking, wherein, (according to advertisements) crop hides are tanned in four months instead of sixteen, without greater expense than oak bark, averaging 8 *lb.* each above the raw halves or standard.

Knowing, gentlemen, that you never wilfully give the smallest countenance to idle and fallacious rumors in your columns, I have felt it my duty to address you upon this matter, being convinced that you are always ready to correct misstatements, by giving them equally public contradiction.

Having observed some remarks published last May, in the British Traveller, also respecting our manufactory at Dorking, we take this opportunity to add a few plain facts, proving the value and utility of our most providential discovery to the trade, to the revenue, and to the nation.

Suppose a tanner turns out 100 cow hides per annum, of 80 *lb.* each, making them weigh 80 *lb.* each when tanned, according to the rules of the old trade (confirmed by Mr. John Underhill, acting chairman of the committee of the Leather-Trade, at Bermondsey, as advertised in the Times of the 27th May last) viz. “that 2 *lbs.* of raw hide are required to make 1 *lb.* of leather.” Such common tanners may be enabled by the use and knowledge of our process (which is both cold and vegetable) to tan 3000 similar raw hides in one year, making them weigh, on fair average, 8*lbs.* each above the raw halves, thus creating 24,000 extra weight of leather! which, at 1*s.* 6*d.* per *lb.* is 1800*l.* per annum additional profit.

Computing the Excise Duty, as lately submitted to the House of Commons, at 655,124*l.* 1*s.* 3*d.* per annum, the weight of leather is above fifty millions of *lbs.* and one-sixth increase of weight (as described above) nearly nine millions of *lbs.* at 1*s.* 6*d.* per *lb.* is no less than 675,000*l.* per annum, derivable by the trade and the public; and if the old duty had not been half repealed, the revenue would have benefited 109,166*l.* per annum, or 54,583*l.* at the present rate of duty.

But duly considering the great advantages of weight alone, it would have been impolitic to repeal the old duty, as the tanners might have been placed better than duty free, while the revenue itself would then have really been about 437,000*l.* more than it is now, and thus (upon moderate calculation) above one million sterling may be annually saved.

I deem all further remarks superfluous, except that I hope every editor who copied the fabulous paragraph will feel it a duty due to the British Leather Company, and to the public, to follow it, by inserting this letter likewise.

I am with due respect, sir, your most obedient servant.

JOHN BURRIDGE, Secretary.

Fuller's Earth.—A gentleman at Sag Harbor, Long Island, forwarded to us sometime since a box of fuller's earth, from a bed which he owns; we put it into the hands of two experienced fullers who have pronounced it to be of an excellent quality.

Connecticut Gazette.

FACTS AND OBSERVATIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY.

FOR THE NEW ENGLAND FARMER.

SALT AND MILDEW.

A correspondent writes us word, that when this subject was mentioned before (1819) he tried salt water for the prevention of this disease, which was then prevailing on his crop; but it had no effect in staying the progress of the disease, and eventually the straw became quite black. As he states that he tried this but on a patch, and took great pains, it seems to follow that such a sprinkling as whole fields could obtain would be entirely useless. We state these facts, as our duty is to prevent delusion, and thoroughly to canvas the merits of a very imposing claim to public gratitude.

Farmers' Journal.

DAMP IN WALLS.

An easy and efficacious way of preventing the effects of damp walls upon paper in rooms has lately been used, and (as we understand) with complete success. It consists of lining the wall, or the damp part of it, with sheet lead, purposely rolled very thin; this is fastened up with small copper nails, which not being subject to rust are very durable, and the whole may be immediately covered with paper. The lead is not thicker than that which is used in the chests in which tea is imported, and is made in sheets, of which the width is about that of common paper hangings.—*ibid.*

POWER OF THE HORSE.

The couriers of Russia travel from Petersburg to Tobolsk, a distance of 19 deg. 26 min. in twelve days. Their rate of travelling is of course about one hundred miles a day. What, in equestrian phrase, is called a great mover, will, without pressing, trot 610 yards in eighty seconds.

DENTIFRICE.

Take sage and salt, of each a like quantity, and pound them together; then bake the mixture till it be hard, and make a fine powder thereof, then therewith rub the teeth evenings and mornings, and it will take away all yellowness.—*Markham's English Housewife.*

FEEDING COWS WITH CABBAGES.

When cabbages are given to milch cows, the decayed and musty leaves must be taken off, or they will impart a bad taste to the milk and butter.

TO MAKE POMONA WINE.

The directions published by Mr. Cooper, of New Jersey, for making wine of cider and other ingredients, which may properly be called *Pomona Wine*, are as follows.—“Take cider of the best running of the cheese, and of the best quality, and add to it as much honey as will make the liquor bear an egg; strain the liquor through a cloth as you pour it into the cask; fill the cask full, with the addition of two gallons of French brandy to a barrel; set it away in a cool place, with the bung-hole open to ferment; as the fermentation proceeds, it will throw out considerable froth and filth; keep filling it frequently with more of the same kind of liquor, kept for the purpose, till the fermentation has nearly subsided; then put in the bung,

ut not tightly, in order that the liquor may have some further vent, and as soon as the fermentation ceases, close up the vessel. The next spring rack off the liquor into a new clean cask; and in order to clarify it take the whites of six eggs, with a handful of fine beach sand, washed clean; stir them well together; then oil a quart of molasses, and cool it by pouring in cider, and put this together with the egg and sand into the liquor, and stir the whole together."

The Farmer's Assistant says, "It is believed that about a quart of sweet milk to a barrel, well stirred and mixed with the liquor as it is poured in, will answer equally well, perhaps better. This operation alone will not only clarify liquors, but by repeating it several times, the highest colored wines may be nearly or quite divested of all their color."

"After the liquor has been thus clarified, let it be again drawn off into bottles, or into fresh clean casks, and kept in a cool cellar for use. Ice, however, is essential for perfecting this kind of wine, as well as all others."

ARBONIC ACID GAS, OR FIXED AIR, NECESSARY IN CIDER.

It is well observed in the Domestic Encyclopedia, that "it is of great consequence to prevent the escape of the carbonic acid, or fixed air from cider, as, on this principle, all its briskness depends. To effect this, various expedients have been contrived. In the state of Connecticut, where much cider is made, it is a common practice to pour a tumbler of olive oil in the bung hole of every cask. Upon the same principle we have lately heard of a man who boasted that he had drank brisk beer out of the same cask for five years, and that his secret was to cover the surface of the liquor with live oil. Dr. Darwin also says that he was told by a gentleman who made a considerable quantity of cider on his estate, that he procured casks of stronger construction than usual, and that he directed the apple juice, as soon as it had settled, to be bunged up close, and that though he had had one vessel or two occasionally burst, by the expansion of the fermenting liquor, yet that this rarely occurred, and that his cider never failed to be of the most excellent quality, and was sold at a great price." Probably casks filled with fresh cider, bunged up tight, and sunk under water or buried in earth, might run no risque of bursting, and no doubt the cider kept in that way would be well preserved, and in time properly fined.

VARNISH FOR IRON OR STEEL.

The Nantucket Inquirer states that "A permanent varnish is obtained by rubbing iron in a state nearly red hot, with the horny hoofs of cattle, which are previously dipped in a small portion of oil; this process is asserted to afford the best defence from the destructive influence of air and humidity."

PATENT HORSE SHOES.

Col. Goldfinch, of Hythe, (Great Britain,) has obtained a patent for a new method in the formation of horse-shoes. The improvement consists in making the horse-shoe in two parts, or separating it in two pieces, by cutting it through near the toes. The object of the contrivance is, that the frogs of the horse's hoof may be enabled to expand and grow in a heal-

thy state. The separation is to be made in an indented form, and the two parts fastened together by pins. It is further proposed to attach the shoe to a horse's hoof, by driving the nails obliquely, as in the French manner of shoeing. For this purpose, the situations of the nail holes are to be from about one third to half the width of the shoe distant from its outer edge, and tending in a slanting direction outwards.

Evening Gazette.

FARMING—CHEMISTRY.

Leland, in his Memoirs of the celebrated French chemist Lavoisier, states, that he cultivated 240 acres of land in La Vendee, on chemical principles, in order to set a good example to the farmers, and his mode of cultivation was attended with so much success that he obtained a third more of crop than was obtained by the usual method, and in nine years his annual produce was doubled.

SMALL CATTLE OFTEN THE MOST PROFITABLE.

[From Anderson's Recreations.]

"Take a mastiff, a greyhound, and a shock dog, whose weights are respectively sixty, thirty, and fifteen pounds each.

"If I have been rightly informed, the quantity of food required to keep these dogs in good condition would be, nearly, for the mastiff, one pound; for the greyhound one pound; for the shock dog three ounces, a day. Of course, one hundred pounds of food would nourish of mastiff flesh six thousand pounds; of the greyhound ditto three thousand pounds; of the shock dog ditto about eight thousand pounds; so that the loss in employing the second, when compared with the first, would be as two to one; and that of employing the second, when compared with the third, would be as two and three-fourths to one nearly.

"The above statement is not given as being absolutely accurate, but merely as illustrative. And as something of the same kind, though not perhaps to an equal degree, takes place between different breeds of cattle as of dogs, it is not a matter of such simple calculation as it has been usually supposed, to ascertain whether it will be the most beneficial in a particular case to adopt a large or small breed of cattle. It is, indeed, impossible that it ever can be done in that general lumping way; for, if ever the real qualities of different breeds shall come to be accurately ascertained, it will, doubtless, be found, that they vary in regard to so many particulars, that perhaps no one rule can ever be made general, because, from the peculiarities of the case and the nature of the circumstances, it may sometimes happen that a large breed may be preferable to a small one, or *vice versa*; and that, by a very small variation of circumstances, the case may be reversed. But if two breeds could be found that were equal in all respects, there are many circumstances in which the small would be preferable to the large.

"In the first place, a small animal, if put upon pasture fields where the surface is a little soft, will be more easily supported than one of larger weight, and not be so apt to poach it.

In the second place, there are innumerable situations in which small beasts will be much better suited to the accommodation of a family than a larger, or in which it would be more desirable to have three or four instead of one. Many a poor person would have abundance of food for

a small cow, who could not possibly maintain one of a larger size; and the quantity of milk that such a cow would yield may be exactly suited to the wants of the family, where a larger quantity would only prove distressful. Persons in moderate circumstances too, where the risk is divided, are much less in danger of being thrown into distress by deaths, than they would be if all were in one; and, as the cows may calve at different times, they are less in danger of being totally deprived of that useful article milk, at one time, and of having it in too great quantity at another. The supply becomes more equal; they never experience either superfluity or want. In like manner, a family that lives in the country, if it be moderately large, can easily consume a small beast of their own killing, whereas a large one proves distressful to them; one half of it must be eaten before it is fit for use, or a great part of it must be thrown away as being tainted. Every person in such circumstances must know, that three or four small beasts would be, to them, of more than twice the value of one that was equal to them in weight.

Lastly, small beasts will always find a ready market, and will usually bring a higher price in proportion to their weight, than large. The very reasons already assigned bring more purchasers. Is it for milk? How many more can reach the price of a small cow than a large one? Is it for rearing? How many have keep for a small one, that could not have it for one of a larger size? Is it fat, and for the butcher? Perhaps in Smithfield market it may make little difference; but in other places there are many who will choose the small in preference to the large. All this is on the supposition that the meat is of an equal quality in both cases; but if it should happen, that the small meat is also finer and more delicate than the large, the difference in its favour would be still more considerable.

"From these considerations it appears, that the mere size of a breed of cattle is not a matter of indifference; and particularly, that those of a diminutive size ought not to be rejected with contempt, as they too often seem to be. They ought rather to have their qualities carefully investigated; because, as we have evidence in the dog species, that some small kinds possess excellent qualities which cannot be found in any that are of a larger size, it may so happen, that similar valuable qualities may be found to peculiarise some of the smaller breeds of cattle. They, therefore, deserve our particular attention; for if any of them shall be found to be truly valuable, they will tend more to augment the comforts of those who are among the most helpless individuals of the community than any other, while they may at the same time add to the luxurious dainties with which the tables of the rich, though plentifully loaded, are not yet by them deemed to superabound."

BUTTER.

This delicate and valuable domestic article, it is known, is manufactured in considerable quantities in Orange county. At a recent cattle show at Goshen, it appeared that John M. Graham made 2535 lbs. of butter from 20 cows.—His farm is only 95 acres; he has 39 hogs kept on milk, which will weigh 200 lbs. each, when killed. Col. Moses Crawford, of Montgomery, produced 2051 lbs. of butter from 20 cows.

From the New-York statesman.

American Hats.—Two fine specimens of domestic fabric—the one a bonnet and the other a gentleman's hat made of the spear-grass—have been politely forwarded to us, and may now be examined at this office. These articles were manufactured by Miss Mary Lamb, of Stamford, Delaware county, a young lady of the age of fifteen, who informs us, that she received no other instructions than were derived from the columns of the Statesman. Her own ingenuity supplied the rest. As the hat was presented to one of the editors of this paper, we hardly dare to speak of these beautiful fabrics in the manner they deserve, lest our opinion in this case should be supposed to be warped by undue biases.—We may at least, however, record the judgment of others, who have pronounced them equal to the best imported Leghorns. It is to be regretted they did not arrive in season for the Fair in this county, and to have been offered for premiums. Miss Lamb, in a polite note accompanying these articles, states “that there is plenty of grass of all sizes on the banks of the Delaware, and willing hands to work it up, could they but meet with a little encouragement.” We hope and trust such encouragement will never be wanting in an enlightened community, whose interest it is to promote female industry. The association lately established in this city for encouraging domestic manufactures, and who are to hold stated Fairs, will be of great service, by becoming the depositories of ingenious fabrics from remote parts of the state, and in cases where the owners cannot be present to superintend the exhibition and sale of their commodities.

We cannot conclude this brief notice, without publicly acknowledging the high compliment paid us by Miss Lamb. Such an honor was as unexpected as it is flattering. A more acceptable present could not have been received. Composed as it is of materials gathered from the fields of our own country, and woven by the hand of one of her ingenious and patriotic daughters, we shall value it more highly than the most splendid fabrics imported from foreign lands; and while it shall shade the brow from the sultry suns of summer, it will be a memorial to cheer us with the recollection of our past exertions, and stimulate us to renewed efforts, in the great cause of national industry.

From the same paper.

Domestic Manufactures.—Our attention has been called to an extensive chemical manufactory, in the village of Greenwich, for the preparation of the following among other articles: Alum, Blue Vitriol, Oil Vitriol, Aq. Fortis, Spt. Nitri Fortis, Nitric Acid, Muratic do, Alcohol, Ether, Vitriol, Tartar Emetic, Refined Camphor, do, Salt Petre, do, Borax, Corrosive Sublimate, Calomel ppd, Red Precipitate, Spts. Nitri, Dile, do, Sal Ammon Fortis, Aqua Ammonia, Flowers Benzoin, Calcined Magnesia, Rochelle Salts, Glauber's do, Sal. Soda, Super Carbonate of Soda, and Tartaric Acid. This manufactory is already in a flourishing condition; but to give it increased facilities and to warrant its extension, notice has been given, that application will be made for an act of incorporation, at the approaching session of the legislature. An establishment so deserving of public patronage and the fostering care of the state, needs no ar-

guments to enforce its claims. The chemical substances prepared in this manufactory are pronounced to be fully equal to the best importations; and as many of the articles above enumerated are expensive, and extensively used in medicine and the arts, it is obviously for the interest of the country to encourage the enterprise and industry of its own citizens, and retain at home the funds, which now go to other nations for the purchase of these commodities.

Judge Pettibone, of St. Charles, Missouri, in digging for water, has discovered Stone Coal of a superior quality, and it is thought of inexhaustible quantity.

THE FARMER.

BOSTON:—SATURDAY, DEC. 7, 1822.

ON SAVING AND MAKING THE MOST OF MANURE.

(Continued from page 135.)

In our last number on the subject of these essays, we gave brief sketches of some of the principal theories which philosophers have from time to time adduced, and endeavored to support, relative to the food of plants. We likewise attempted to point out defects in those theories, and gave some reasons for entertaining a preference for the hypothesis of Sir Humphry Davy, which is, in substance, that no one kind of matter can be considered as furnishing the food of plants, but that vital air, [oxygen] charcoal, [carbon] inflammable air, [hydrogen] and that kind of gas or air, which forms a great part of the atmosphere, and which is not respirable, and will not support combustion, and is called azote, [nitrogen] form the principal sustenance of plants. It is true that other substances are found in plants by chemical analysis, but some of those substances are, probably, accidentally introduced, and others though generally esteemed simple bodies, are most likely to turn out compounds, whenever chemical analysis shall be carried to the degree of perfection which some modern discoveries appear to promise.* “The four earths

* Although the elements which constitute the greatest part of organized vegetable matter are oxygen, hydrogen, and carbon, yet a little nitrogen or azote is found in some of the products of vegetation, such as albumen, gluten, &c. But “from some late experiments it seems probable that nitrogen is not a simple substance.—See Phil. Mag. vol. xxxiii. p. 173. Indeed the experiment of Dr. Priestly, by which he procured several portions of nitrogen from the same distilled water, by repeatedly freezing it, seems to confirm this opinion.—See Nicholson's Journal, 4to. vol. iv. p. 137. But the novel experiments of Sir Humphry Davy are more to the purpose. From these it would appear that nitrogen is a compound of hydrogen and oxygen.—See Phil. Trans. for 1809. Priestley conceived it to be a compound of oxygen and phlogiston.—See his pamphlet entitled “Experiments and Observations relating to the Analysis of Atmospheric Air, &c. 1796, p. 11.”—*Parkes's Chemical Catechism*, p. 47, 10th ed.

It seems then, that although some vegetables exhibit, on chemical analysis, nitrogen, as well as carbon, oxygen and hydrogen, yet, as the first mentioned is only a compound of the two last, we may omit it in our table of the chemical products of vegetation, except when, in common parlance it may be convenient to retain a term in common use. Moreover, the oxygen and hydrogen found in vegetables are, we believe, generally, combined in the proportions, which constitute water. Of course carbon and water compose nearly the whole substance of vegetable matter; the carbon being, for aught that yet appears, a simple substance, and the water a compound of oxygen and hydrogen. Here we have a further approximation to M. Braconnet's theory, (as stated No. 17, p. 131.) that “oxygen and hydrogen, with the assistance of solar light, appear to be the only elementary substances employed in the con-

(viz. clay, sand, lime and magnesia) the various acid the alkalis, the oxids of iron and magnesia, and several saline compounds, all find their way, through the medium of the sap either suspended in it mechanically or combined with it by chemical affinity, into the heart of the organized structure. I am not certain whether it be very correct, in point of language, to describe these as constituent parts of the food, because they are detected in plants on incineration, and other modes of analysis, any more than it would be warrantable to call lime, phosphorus, sulphur, and a multiplicity of acid constituent parts of animal food, on the simple ground of their being found in the bones and secretion of the body; so that the common doctrines of exalting whatever may be yielded on analysis into the pabulum of vegetation, is both questionable and dangerous philosophy, and the rather, because it is a known fact that ashes of many plants abound with substances predominating in the soil that produced them. We shall, in all probability, come nearer to the truth, by considering the putrescible manures, and the sap only, as the elements of food; and the other bodies as subservient, though in a less degree, to the health, solidity, strength, or the right performance of the vegetable functions.”

Carbon, oxygen and hydrogen, being the constituent substances which make up the various products, formed by the wonderful process of vegetation, it may be considered as but little short of a perpetual miracle that so many and such diversified ingredients should be the results of different modifications of those two or three simple elements. Sir Humphry Davy states that “the compound substances found in vegetables are 1, gum, or mucilage, and its different modifications; 2, starch; 3, sugar; 4, albumen; 5, gluten; 6, gum elastic; 7, extract; 8, tanom; 9, indigo; 10, narcotic principle; 11, bitter principle; 12, wax; 13, resins; 14, camphor; 15, fixed oils; 16, volatile oils; 17, woody fibre; 18, tannin; 19, alkalies, earths, metalli oxides and saline compounds.” These substances, many of which appear to possess qualities diametrically opposite, are, notwithstanding, composed of the same elements, but in different proportions.

Thus 100 parts of sugar contain	23 carbon, 8 hydrogen, 64 oxygen.
100	
100 parts of acetic acid or vinegar, contain about	50 carbon, 6 hydrogen, 44 oxygen.
100	
100 parts of olive oil about	77 carbon, 10 oxygen, 13 hydrogen.
100	
100 parts of the wood of oak about	52 carbon, 42 oxygen, 6 hydrogen.
100	

stitution of the whole universe.” If carbon, like nitrogen, can be resolved into oxygen or hydrogen, or a compound of both, or can be supposed to be compounded of “solar light” and oxygen and hydrogen, or either of them, we have M. Braconnet's theory advanced another step towards proof positive. M. Braconnet's vegetables obtained various earths, alkalies, acids, &c. either from atmospheric air, which consists of oxygen and azote, with a minute quantity of carbonic acid, or from water (oxygen and hydrogen.) The carbon found in them by analysis might be taken from the carbonic acid gas of the atmosphere. The other products thus found, it should seem, must have been derived from distilled water, or pure oxygen and hydrogen.

* Letters of Agricola.

100 parts of albumen from the white of the egg about

5.3 carbon,
21 oxygen,
7 hydrogen,
16 nitrogen.

100*

Nitrogen is rarely found in vegetables, but "the incipial part of the almond, and of the kernels of many other nuts, appears from the experiments of Proust, to be a substance analogous to coagulated albumen, or hite of an egg."

The above are the principal elementary substances which enter into the composition of all vegetables. Those of animals are nearly the same, the only material difference consisting in the uniform presence of nitrogen in animal matter. When vegetables are growing they imbibe or make food of these substances either by their leaves or their roots, but principally by the latter. Any thing that has ever breathed or vegetated, at has or ever had lungs or leaves, may constitute anure or the food of plants. The moment that animal or vegetable life is extinct in any individual of either of those kinds of beings, the process of decomposition (in the ordinary temperature of the atmosphere) commences. This decomposition is effected by putrefaction, which is more or less rapid, according to the temperature of the atmosphere, and other circumstances, more or less favorable to the dissolution of the decaying body. Putrefaction, however, cannot take place without the aid of water and air; and caloric, or that matter which communicates to us the sensation of heat is likewise an indispensable requisite of this process. During the progress of fermentation, however, not a particle of the decaying substance is annihilated, but the minute and invisible atoms of carbon, oxygen and hydrogen, which formed the body which decomposing, are unlocked or unclenched, or otherwise set at liberty; and are ready to enter into new combinations. These particles or atoms every good farmer will, as far as possible, arrest and convert to the use of his plants, by means which have been heretofore in part explained, and will be further elucidated hereafter in the course of these essays.

We have now given a few brief and imperfect sketches of some subjects connected with agricultural chemistry, partly with a view to render the topics of which

* We have omitted the fractions in the numbers expressing the proportions of the constituents of the vegetable substances here enumerated, from a desire, as much as possible to simplify the subjects of our remarks.

† The following lines from Creach's Lucretius may, perhaps, induce the reflecting reader to frequently turn his mind's eye to objects of great importance, although small for corporeal vision.

Know there are bodies, which no eye can see,
And from their effects, we grant to be,
First the winds disturb the seas, and tear
The stoutest ships, and chase the clouds through air;
The numerous odours too, whose smells delight,
Delude the nose are all too thin for sight;
Beside fresh clothes extended near the main,
How wet; but by the sun are dried again.
What eye saw when first the moisture sate?
When it rose, and fled before the heat?
Therefore we must conclude the drops I have been
Solv'd to parts too subtle to be seen.
More, 'tis certain every circling year
The rings, which grace the hands diminish there,
Rings wear out stones, and while we plough, the share
Cuts less.

Lastly, not even the sharpest eye e'er sees,
What parts to make things grove by just degrees
Nature does add; nor what she takes away
When age steals softly on, and things decay,
The same seeds compose both earth and seas.
The sun, the moon, all animals and trees,
And their contexture, or their motion disagrees.

we are treating more intelligible than would otherwise be possible, and partly with a hope of turning the attention of the young agriculturist to a science, which is almost as necessary for a farmer, as a knowledge of arithmetic for a merchant or accountant. We will conclude this number with some reflections quoted from the celebrated "Letters of Agricola," which may perhaps suggest a new and useful train of thought to some of our readers.

"One is not able to contemplate the putrefactive process, and the uses it serves in the vegetable kingdom, without being struck with this admirable contrivance of Divine Wisdom to remove from our sight the putrid remains of animal and vegetable bodies, and change them into new and nutritious forms. The beauty of the universe would have been marred, and our senses continually offended, without this expedient of putrefaction which sweeps away all trace of former organized beings, by converting them into pure and uncontaminated gases. These retain no tincture of their former corruption, and are ready to enter into new bodies invested with all the attributes of healthful, cultivating and agreeable existence. The vegetables cooked for our table, the butcher-meat under which it grows, are no other than new combinations of those putrid and nauseous steams, which, in the act of passing off, assailed our nostrils with ungrateful odours. The dunghill which the farmer carts to the neighbouring field, returns to him at harvest in the shape of useful roots or yellow sheaves, free from all polluted admixture, and refined from the dross in the elaboratory of vegetation. I know no indication of greater skill in the Divine Intelligence, nor a more indubitable mark of his care and goodness, than this contrivance of resolving all dead animal and vegetable matter into elementary principles; that, in the first place, he might relieve the earth of such leathsome incumbrances, and in the next place, be supplied with fresh materials out of which to form and sustain the new and successive families of plants.—In a similar manner the excrementitious matter passing from man and all other animals is disposed off. In the form of manures, it is buried in the ground, which absorbs all its noxious effluvia; and in place of exciting in us revolting sensation, it becomes the most powerful restorative of our exhausted fields. There it is decomposed by the solvent powers of heat and water, and supplies abundance of nourishment to the grasses and corn vegetating over it."

(TO BE CONTINUED.)

A singular instance of Hydrophobia.—A boy about 11 years of age, whose name was Isaiah Kendrick, in going after the cows of Mr. Gregory Stone, of Lincoln, Mass. passed a pair of bars, in or near a piece of woodland, and saw a Racoon, which instantly flew at the lad, caught him by the thumb and held fast. The boy's cries were heard by Mr. Stone, who ran to his relief; but he was unable to rescue the boy from the jaws of the animal, till he drew his knife, and cut the throat of the racoon. In six weeks from that date, the boy was taken with madness, died on the 29th ult. and was buried on the 1st instant.—Communicated.

FARMER SUMMARY OF FOREIGN AND DOMESTIC EVENTS.

Lieutenant Commandant ALLEN of the United States' Navy has fallen in a contest with pirates. A letter from Havana, giving an account of his death, states that "This brave man fell in an action against the pirates on the 10th inst. in the Bay of Sigüapa, about 50 miles north of Matanzas, after a most desperate engagement, which terminated in the capture of the principal piratical vessel, a beautiful schooner of about 80 tons, mounting one long 18 pounder and four other guns, and the recapture of 5 American vessels. The Alligator [the vessel commanded by Capt. Allen] lost in the engagement two sailors killed, two mortally wounded, and three slightly wounded." Capt. Allen was buried at Matanzas, and every respect shown by the public authorities and inhabitants, which was suitable to the melancholy occasion.

The Prize of a Silver Cup, offered for the best poem, which might be composed on the occasion of opening a new building for a theatre at Philadelphia, has been awarded to Mr. CHARLES STRANGE of Boston, who was the successful competitor for the prize medal at the opening of the New-York theatre about 12 months since.

Northern Cotton.—Mr. William Ladd, of Cyster Bay, (L. I.) has sent us a fine cotton plant, well stocked with full bolls, which are now opening in the printing room of the Commercial Advertiser.—N. Y. Spectator.

The Western Monitor, (a valuable newspaper printed at Lexington, Kent.) of the 12th ult. gives notice that a Mr. Thomas Pullen, of Bourbon County, has exhibited a newly invented machine for dressing hemp and flax, by which "the anticipations of the public were fully realized."

A London paper states that upon Mr. Rhodes' Estate, near Islington, the foundations are laying for the erection of two thousand seven hundred houses. Mr. Rhodes is one of the most extensive cow-keepers in the vicinity of London, and a very considerable portion of the metropolis is supplied with milk from his dairies. This is a great story, even if the houses are cow-houses, of small dimensions.

Chillicothe Twin Cattle.—A Chillicothe paper tells of two twin Cattle, a steer and an heifer, seven years old, owned by George Remick, Esq. of that neighborhood. The steer weighed alive, two thousand nine hundred & ninety-six pounds. The heifer is nearly as large as the steer, and is supposed by good judges to weigh within 200 pounds as much, but as she appeared somewhat wild, it was deemed unsafe to weigh her.

A machine for the dressing of cloth has lately been erected in Leeds, (Eng.) which, according to an English paper, does as much in forty-five minutes as two men could do in two days.

An English paper states, that, by the late population report, there are in England 57, in Wales 3, and in Scotland 40 men 100 years old and upwards.—Of women there are in England 111, in Wales 18, in Scotland 62, 100 years old and upwards. By a statement in the New-Hampshire Patriot, it appears that 75 persons have died within that State, since 1732, who had attained the age of 100 years and upwards; of these, one reached 129, another 116, and a third 115 years; and there are still living in that State the following persons who are more than 100 years of age, viz. Tryphena Stiles, of Somersworth, 101; Sarah Kelley of New-Hampton, 103; Mrs. Bailey, of Chesterfield, 101; Mary Barnard, of Amherst, 101; and Samuel Welch, of Bow, in his 113th year.

Fisheries of Lake Superior.—It is stated in the Detroit Gazette that fishing upon an extensive scale has commenced on Lake Superior, and that one man has already taken two hundred barrels.

A gentleman in Bennington, Vt. has raised a crop this season, on six rods of ground, for which he received 124 dollars and 68 cents, cash.

Caution.—Some of the notes of the Farmers' Exchange Bank, Gloucester, (R. I.) which failed some years ago, have been put in circulation in New York.

An Apprentices Library is about to be established at Portsmouth.

Two noted gamblers from New York, were lately convicted at Baltimore of keeping a gaming table, and fined \$330.

A numerous mission family, consisting of 18 persons, sailed from New Haven on the 20th Nov. for the Sandwich Islands.

An extensive quill manufactory has recently been established at Philadelphia.

A splendid eruption of Mount Versuvius occurred on the night of the 6th Sept. unaccompanied by earthquake.

On the 26th Sept. William Haygate, Esq. merchant tailor, was elected Lord Mayor of the city of London.

Two men have been arrested in Fredericksburg, Va. for passing counterfeit money; upwards of \$6000 in spurious notes were found concealed in one of their trunks, and were remarkably well executed.

The number of under graduates at Yale College in 371—medical students 92—resident graduates 12—making a total of 481.

SELECTED FOR THE NEW ENGLAND FARMER.

RURAL SCENERY.

See where the farmer, with a master's eye,
 Surveys his little kingdom, and exults
 In sovereign independence. At a word,
 His feathery subjects in obedience flock
 Around his feeding hand, who in return
 Yields a delicious tribute to his board,
 And o'er his couch their downy plumage spreads.
 The peacock here expands his gorgeous plumes,
 A glittering pageant to the mid-day sun;
 In the stiff awkwardness of foolish pride,
 The swelling turkey apes his stately step,
 And calls the bristling feathers round his head.
 There the loud herald of the morning struts
 Before his cackling dames, the passive slaves
 Of his promiscuous pleasure. O'er the pond,
 Behold the gambler, and his female train,
 Bending their lofty necks; and gabbling ducks,
 Rejoicing on the surface, clap their wings;
 Whilst wheeling round, in airy wanton flights,
 The glossy pigeons chase their sportive loves.
 Or in soft cooings tell their amorous tales.
 Here stacks of hay; there pyramids of corn,
 Promise the future market large supplies;
 While with an air of triumph he surveys
 His piles of wood, and laughs at winter's frown.
 In silent rumination, see the kine,
 Beneath the maple's shade, patiently wait
 To pour into his pails their milky stores.
 These his amusements, his employments these;
 Which still arising in successive change,
 Give to each varied hour a new delight.
 Peace and contentment with their guardian wings
 Enclose his nightly slumbers. Rosy health,
 When the gay lark's sweet matin wakes the morn,
 Imprints her dewy footsteps round the field,
 And cheerfulness attends his closing day.
 No racking jealousy, nor sullen hate,
 Nor fear, nor envy, discompose his breast.
 His only enemies the prowling fox
 And haggard wolf, that thin the bleating fold;
 The bristly porcupine, the cruel hawk,
 With eye malignant on the little brood
 Sailing around portentous.
 The amphibious otter bold; the weasel sly,
 Pilfering the yolk from its enclosing shell;
 And moles, a dirty undermining race.
 These are his foes, and these, alas, command
 With man to man an inoffensive train.
 'Gainst these assisted by the entangling net,
 The explosive thunder of the level'd tube,
 Or toils unwearied of his social friend,
 The faithful dog, he wages rural war,
 And health and pleasure in the sportive field
 Obtaining, he forgives their venial crimes.

Pigs in the character of Ministers of Justice.

An old English writer gives the following account of a signal instance of justice performed by pigs.—Certain pirates, who seem not well to have learned their business, since they were unable to swim, had landed on the coast of Tuscany, and carried off the swine from a farm. As the robbers were paddling off from the shore, their keeper returned and blew his horn, by which he had been accustomed to call his swine to their meals. At the well known sound, the grunters all started up, and crowding to one side of the boat, overturned it, and swam ashore to their keeper, leaving the unfortunate thieves to drown.

A HORRID SCENE OF CRUELTY.

The following is taken from *Lawrence's Treatise of Neat Cattle*. The author is an Englishman, whose works have been praised in British Reviews and quoted with approbation in British Cyclopedias, and other works of science. We do not give this relation by way of stigmatizing the lower orders of the English as peculiarly atrocious, nor by way of balancing the charges which some foreigners have exhibited against Americans, for not being so civil, humane, enlightened and highly polished as their brethren on the other side of the Atlantic. But we exhibit it by way of shewing what ferocious animals mankind are, when they can divest themselves of the restraints which religion and the regulations of society impose upon their passions and propensities.

"I give place to the following anecdote, from a sense of duty, and by no means in a frame of mind, to treat the subject in a tender, still less in a ludicrous way. Far from thinking that the knowledge of flagrant acts of cruelty should be delicately hushed and suppressed, in my opinion, they cannot be proclaimed too loud, or disseminated too widely, for the purpose of raising a general abhorrence, exciting a due sense of shame, or imparting the needful information to those whom custom and prejudice hold in a contemptible and degrading state of ignorance. I dare trust myself with making few remarks; indeed the bitterest language of execration would fall far short of what is due to the enormities of the tale to be told; the senseless and beastly actors in which are, however, inferior in guilt to the cool, deliberate, and argumentative defenders of such infernal games. "November the 5th, last, at Bury, a bull, naturally gentle! which had in the morning, previous to baiting, been privately baited, and goaded with sharp instruments, in order to render him furious, though tied down with ropes, in his agony from being worried by dogs, and goaded by more inhuman dogs in human shapes, burst his ropes, to the terror of his tormentors, and the no small danger of the peace of the inhabitants: after this, the poor beast was doomed to be the victim of the still greater barbarity of fresh tortures—he was entangled again with ropes, and, horrible to relate, his hoofs were cut off, and he again baited while he had to defend himself on his mangled, bleeding stumps. The magistrates of Bury have repeatedly tried to prevent such infernal, demoniacal proceedings; but the demons are sanctioned, it seems, by AN ACT OF PARLIAMENT! Surely such an act is highly disgraceful to the age we live in, and to this country. Extracted from a magazine; and sorry I am to observe, that no doubt need be made of its authenticity. Should this account chance to fall into the hands of actors in scenes like these, or into those of the still more guilty palliators of them (for hypocritical extenuation is infinitely the greater crime,) I beg of them seriously to reflect on the possibility of those tortures, which they have thus wantonly inflicted, although upon a poor and friendless beast, intruding upon their minds, when their own bodies may be racked and tortured with disease, perhaps on their death bed, and in their last agonized moments. Will they then think, that the infliction of torments upon one animal ought to convey pleasing and mirthful sensations to the breast of another?"

3000 persons are said to have attended an Oratorio at Philadelphia last week

PATENT GRIDIRON.

New-York, 12th Nov. 1822.

To Mr. Mussey.

I willingly, sir, give you my opinion on your patent, economical utensil, the hollow-barri Gridiron, with a Reflector and a Dripping-Pan.

Broiling has been considered as the most saving, but at the same time the most wasteful way of cooking meat. Your invention removes in a great measure, from this operation, the charge of extravagance, by saving the fat and juice from destruction by the hot coals. The rays of heat, repelled from the bright surface of tin, add to it the valuable properties of the Dutch oven. Having satisfied myself by experiment that it is admirable in a saving manner, I recommend your gridiron and its appendage, as a piece of kitchen apparatus, to all house-keepers who are desirous of combining the luxury of eating with frugality in cooking.

SAMUEL MITCHELL.

N.B. The above Gridiron may be seen at this office, and orders received for them.

N. Y. Nat. Adv.

Rare Sport.—A Farmer who lived on the lakeshore, observing a bear crossing a bay was anxious to kill him. He ran to his skiff and without reflecting that he had no weapon but a paddle, worked his way to the bear, who immediately sprung into the skiff, and to the great terror and consternation of the farmer, very deliberately sat down on the bow. The Farmer after some reflection, determined to carry him back and attempted to turn the boat, but the bear made an advance to prevent him, and the boat, impelled by the wind having gained its first position the bear again very quietly took his seat on the bow. The farmer made a second and third attempt with always the same result; a perceiving that when the boat went the way the bear was swimming, he was quiet, he very prudently determined to reach the land in that direction. He accordingly went on, and when he was within a few feet of the shore, the bear leaped out, to the great satisfaction both himself and the ferryman.—*Western paper*

Franklin.—It is rather a curious incident that when the Americans sent Dr. Franklin, a printer, as Minister to France, the Court of Versailles sent M. Girard, a bookbinder, as Minister to Congress. When Dr. Franklin was told it, "Well," said he, "I'll print the Independence of America, and M. Girard will bind it."

In the year 1776 a Bill was introduced in the British House of Commons, for the better watching of the Metropolis, in order to effect which object one of the clauses went to propose that watchmen should be *compelled* to sleep by day. Lord Nugent, with admirable humor, got up, and desired that he might be *personally* included in the provisions of the bill, being frequently so tormented with the gout as to be unable to sleep by day or by night.

To desire little makes poverty equal with riches. He who wants, is not rich; nor he who wants not, poor.—Riches are not to be measured by their use; I cannot call large possessions rich, but so much as is conducive to comfort.

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I. BOSTON, SATURDAY, DECEMBER 11, 1822.

No. 20.

From the National Aegis.

MINERALOGICAL.....No. IV.

In the estimate of the wealth of our country, the Anthracite, or as it is here improperly called the Black Lead, should not be omitted. As a combustible it resembles Coal in many circumstances of its character, and for many uses is preferable to that mineral. Altho' there is some difficulty in igniting it in the first instance, yet when the process of combustion is once commenced it goes on with rapidity. The heat which is produced is intense, and its production is unaccompanied with smoke. For the smelting of ores, for the conversion of Iron into steel, in the firing of Lime-stone; in distillation, and in those mechanical operations where the desiderum is a strong, durable, and continued heat, it may be employed with singular advantage. It has not here been used as fuel, but there is no doubt that it would succeed on experiment equally well, as the same substance in its application to this use, when dignified by the name of Rhode Island Coal. It is the opinion of a distinguished mineralogist that a broad vein of anthracite crosses this section of country passing from Rhode Island, thro' Worcester, into New Hampshire. It has here been converted into paint, which forms a cheap and durable covering for the roofs of buildings. In a region where the forests are daily receding before the eye of cultivation, it will become necessary to provide a substitute for the growth of the ancient wood. That this substance may become valuable for such a use, admits of little doubt.

Another individual closely associated with that to which we have alluded, is the Graphite, deriving its appellation from the facilities it affords in the art of writing, but which has been equally unfortunate as its neighbour in receiving name. It forms the material of those crayons erroneously known, by the term, Black Lead pencils. These misnomers are of little consequence in themselves but are adverted to merely because correctness is preferable to error.

The Sulphate of Iron, the Copperas of Commerce exists in many of the rocks of our country and is discoverable by analysis to be held in solution in some instances in the waters which read themselves over the surface of meadows. Altho' perhaps, in sufficient abundance to prejudice vegetation, yet it would not form an advantageous article of manufacture.

The Slate which appears upon the surface in numerous localities is quarried in but few. When the villages of the present day shall be built into towns, when the spires of the city shall take the place of the more modest habitations of the town, when a dense population shall be gathered upon the borders of the highways, these will furnish employment for industry and supply materials for building.

In the catalogue of those substances which are valuable to the Farmer, we have not included those which gratify the eye of the scientific observer only to ornament the shelves of the cabinet. Nor shall we trespass longer upon the patience, which we fear has already been so severely tried, by making such an enumeration.

Although there is much here to invite attention, we shall not delay to note the brilliancy of surfaces, the changing colors, the variety of form or the curious structure of those which belong to a stricter and more scientific survey. The crystals of Quartz, a mineral which pervades every region, here often tempt the unskilful, with the promise of countless treasures of diamonds, those who take all that glitters for gold, have often fancied that the lustre of the beautiful cubes of Sulphuret of Iron, was the splendor of a more valuable metal, and the exercise of a moderate warmth of imagination has converted the little plates of Mica, into spangles of Silver.

Although the promise that was given to shew the advantages of the study of Mineralogy, has been but inadequately performed, yet we trust it will have been seen that its cultivation is not of doubtful utility to the farmer. His daily toil is required for the daily necessities of a busy life. Yet there are many intervals of leisure which may be occupied in the acquisition of information, without prejudice to his more pressing, but not more important business. If the object of his labours is the acquisition of wealth, it were folly to overlook the course which leads most directly to it. To travel on, in the same path which our fathers have trod, without understanding whether it is the best, or knowing those roads which may be more easy and direct, discovers but little wisdom. Nothing is so inimical to the progress of improvement as ill-founded prejudices, hastily embraced but warmly defended. This inveterate attachment to old customs is valuable, so far only as it discourages rash innovations. When it closes the ears, to propositions for experiments which are supported by reason and recommended by probability, it is illiberal and unworthy of men who are competent to think as well as act for themselves.—“To him that hath shall be given” is a maxim as true in science and agriculture as in morals. The more numerous are the principles which are learned, the more numerous will be the streams which will bring information to the mind, from its increased powers of observation and reflection. The greater the amount of knowledge, the greater will be the means of increasing property, by better methods of tillage, and by the superiority of management. If Marble exists it should not remain in its native beds when it might be employed in spreading fertility around in its vicinity. If the harvests have been blasted, let us seek out the causes of the evil, and take this first essential step towards its removal. If the Wheat and the Rye have not succeeded on our hills, let us ascertain what peculiar properties in our soils have been unfriendly to them. Let the owner of land, ask of himself, what are the qualities of the plain, or the meadow, what are requisite and proper for the nourishment of the grass or the grain, and what applications are most suitable to restore its riches to the exhausted field? If these questions cannot be answered in a satisfactory manner, let him have recourse to those simple processes which are offered to him, by those who have employed their powers in these investigations. Who

would be ignorant of the elements of the profession in which he is occupied? Who would be liable to continual errors in practice and constant disappointment as their unavoidable consequence, when the want of those few principles which have occasioned them, might be so readily supplied. Few men are so destitute of curiosity, as to be intimate with objects around them for years, and never to feel an inclination to become acquainted with their names. And why should we be content to stumble over the rocks, that are strewn along our pathway, without even looking upon them and determining how far they may be valuable?

The great difficulty which has been encountered by those who have advanced far in the science of Mineralogy, is one which need not even be met by him, who does not purpose to fathom its depths and penetrate its secrets. The absence of an organic structure, of those fixed and certain marks which are the distinctions of other classes in the great family of Nature, have rendered it a matter of great nicety to determine the proper place of many individuals in the system of a strict arrangement. But where it is only required to know the appellations which should be given to a limited number of subjects, whose characters are well defined, which are obtruded upon the notice at every step, this objection is not applicable. He who has once attentively considered the appearance of a mineral, will not fail to recognize it again under any circumstances. The memory is so strongly impressed with the features of the friend who often comes before us, that we do not hesitate to annex his name to his face even among strangers. Yet it would be no easy task to describe his person, to another, so accurately as to enable him to fix upon him whom it may be intended to point out. This fact, for such it is, which gives the power of determining our acquaintance, is similar to the skill which ascertains at sight the specimens of the cabinet. When the first advance is made the greatest obstruction is overcome, and the subsequent progress is pleasant and easy.

Having so long plodded on, with sober matter of fact and experiment, we may be justified in wandering for a moment into the regions of speculation. In another number this communication will be concluded with some general observations on its subject.

From Sinclair's Code of Agriculture.

On Promoting the Collection and Diffusion of Useful Knowledge.

“It is a saying sanctioned by the authority of Bacon, that *“knowledge is power.”* Of all the various sorts of power, enumerated by that great philosopher, this seems by far the most important. What gives one man any real superiority over another, but the knowledge he possesses? What enables some individuals, to produce abundant harvests,—to carry on a prosperous commerce,—to establish successful manufactures,—to excel in mechanism, or any other useful art, but the acquisition, and judicious application of that knowledge, in which others are deficient.”

"That the power and prosperity of a country, depend on the diffusion of useful knowledge, can hardly be questioned; and there is probably, no art, in which a variety of knowledge, is of more essential importance, than in that of agriculture. The extent of information necessary to bring it to any thing like perfection, is far greater than is generally supposed. To preserve the fertility of the soil;—to free it from superfluous moisture;—to cultivate it to the greatest advantage;—to raise its productions at the least expense;—to procure the best instruments of husbandry;—to select the stock likely to be the most profitable;—to feed them in the most judicious manner, and to bring them to the most advantageous markets;—to secure the harvest, even in the most unpropitious seasons;—to separate the grain from the straw with economy and success;—and to perform all the other operations of agriculture in the most judicious modes, require a greater extent, and variety of knowledge, than might, at first view, be judged requisite.

"But though a general knowledge of agriculture, may be diffused over a great country, it is found by experience, that it cannot be materially improved, unless by comparing the various practices which subsist, in different parts of the same kingdom. One district has been led, to pay a peculiar and successful attention, to one branch of husbandry, or by a fortunate accident, some important discovery has been made in it, while other districts excel in other particulars of equal importance."

EXPERIMENTAL FARMS.

"The art of agriculture, can never be brought to its highest degree of perfection, or established on rational and unerring principles, unless by means of experiments, accurately tried and properly persevered in. The ardent inquirer has too long been obliged, to rely on vague opinions, assertions which have not been warranted by sufficient authority; it is full time, therefore, by the establishment of experimental farms under the sanction, and at the expense of government, or by enabling the Board of Agriculture to grant adequate premiums to deserving persons, for new discoveries, to bring the art to as great perfection as possible, by ascertaining the principles on which it ought to be conducted.

"It is alleged, that there are many distinguished characters, who carry on experiments for their own information and amusement, by means of which, every important fact, will in process of time be ascertained; and it cannot be doubted, that their example is of very great advantage to those, who have the means of examining the progress that is made. Their farms, however, are more properly speaking, *pattern farms*, for the advantage of the farmers in their immediate neighborhood, than experimental ones, in the strict sense of the word; and they are too often, rather the partial records of successful experiments, than the faithful journals of success and of disappointment. In order to render experimental farms generally useful, they ought to be open to the inspection of the public; the account of each experiment ought to be regularly published, and every new practice, likely to improve the cultivation of any considerable part of the kingdom, ought to be examined with the utmost precision, every trial repeated for confirmation, and, if possible, made by different

persons, in different places, and on different soils.

"It cannot be expected, that persons of high rank, whose attention is necessarily directed to other objects, should renounce their ordinary pursuits, and devote themselves exclusively to the conducting of agricultural experiments; but if one or more experimental farms were established, under a proper system, it would ere long be discovered, what practices ought to be avoided, as well as what ought to be pursued. It is important, that the one should be made known as well as the other; yet *errors in husbandry*, are seldom communicated to the public, or known beyond the sphere of a confined neighborhood, because a farmer is in general ashamed of acknowledging his want of success. Unfortunately also, when his experiments answer, they are sometimes concealed, lest others should avail themselves of the discovery. The object of an experimental farm, however, should be to ascertain facts, and to publish them; and as much credit would be acquired, by an intelligent conductor of an experimental farm, for his exertions in detecting errors, as in establishing facts likely to be useful."—*ibid.*

FIRST VIRGINIA CATTLE SHOW.

The American Farmer of the 6th inst. contains an account of the proceedings of the Fredericksburg Agricultural Society at a meeting held on the 13th and 14th of November; and of the Cattle Show exhibited on this occasion; which it appears was the first which has been exhibited in Virginia. At this meeting, resolves were passed, approving of the proposition of the Albemarle Society for the establishment of an Agricultural Professorship at the University of Virginia—for presenting the thanks of the meeting to J. S. Skinner, Esq. editor of the American Farmer, "for the many instances of polite attention to the interests and wishes of the Society, which we have experienced at his hands, and for his meritorious labors in the cause of agriculture generally;" and approving of the "elegant workmanship displayed on the premium plates awarded by the society; and, that the artist, Mr. Warner, of Baltimore, be respectfully recommended to the patronage of our sister societies."

Among the premiums awarded were a silver pitcher with emblematic device and description, cost \$33, to Mr. Ira Lipscomb, for a fine stallion; a silver pitcher, which cost \$28 to Col. George Love for his bull Pluto, besides a silver cream cup and several silver mugs to several individuals for fine animals of different kinds. Likewise a silver mug, value \$15, to Mr. McCormish for the best plough; and also a discretionary premium of \$5, for an Angular Balance, by which to ascertain the force necessary to move a plough. Among the articles exhibited were Pine-Apple Cheeses, a Wheat Fan, two Cutting Boxes, a Drill Plough for planting corn, a beautiful Counterpane, &c.

The mode of trying ploughs by a force equal to a certain number of pounds weight, has not,

so far as we know, been adopted in New-England. We therefore give that part of the account entire as it may perhaps suggest useful ideas to some of our agriculturists.

"Of the Ploughs, there were only three tried: McCormick's, Wood's or Freeborn's, and Cochran's. The committee here subjoin the calculations, and leave it to the public to decide.

M'CORMICK'S.

	Width of Furrows.	Depth.	Force.
1st trial	16 inches	7 inches	38
2d do	11	8½	38
3d do	15½	7	38
4th do	14	7½	38

FREEBORN'S.

	Width of Furrows.	Depth.	Force.

2d do	11	5½	38
3d do	11	5	38
4th do	11	4	34

"But the most singular exhibition of all, and one that caused general amusement, was the spectacle of two little goats completely harnessed and attached to a cart, in which sat the driver, a man weighing nearly 200 pounds, who coursed his proud looking little steeds about with much apparent ease and security. They were perfectly tractable and true to the draft. This equipage, although intended by the worthy proprietor merely for amusement, conveyed a good practical lesson to husbandmen. It showed in a striking manner, what things may be accomplished with our domestic animals by a proper course of education."

The second day the following toasts were given:

1. *The Day we celebrate*—May each return to it invigorate our zeal, and augment our professional knowledge.

2. *Our soil and our Intellects*—We must give better culture to both, or the first will soon change masters.

3. *Free Exports and Imports*—The best security for regular demand and supply.

4. *The Congress of the United States*—Would they give Agriculture more of their works, and less of their faith; Agriculture would give them more of her money, and less of her complaint.

5. *Fair, free Trade and Universal Commerce*—The best pioneers, for liberty, knowledge, and universal good government.

6. *Prohibitory Duties, and the self-flagellation of Sancho Panza, plants from the same nursery*—A fool's cap, with ass's ears, is due to the inventors of both.

7. *Moderate and competent profits to all, except extravagant ones to none.*

8. *Steady and regular prices to every occupation, the healthful trade-winds of national prosperity; exorbitant gain, the tornadoes that ruin them all.*

9. *Our Plough-shares and our Swords*—May the first never be lost, nor the last first.

10. *Speed to our Ploughs; industry, skill and honesty to their drivers; and a prudent enlightened economy to the owners of the soil.*

11. *Banks*—The most appropriate ones for agriculture, are those erected by the Spade.
 12. *The Land and the Ocean*—The value of the first, much depends on the free use of the last.
 13. *The Matrons and Maidens of Confederate America*—Our last toast, but the first objects of esteem and affection.

An Address was given by Mr. Garnett, which we propose to republish in a future number.

A writer in the American Farmer with the signature "Hugh Hartshorn," says, "If not generally known, it may be useful to mention a very easy and excellent method of making butter, in winter, or in cold weather, late in the fall. We began it last fall, and have practiced since with uniform success. It consists simply in heating the cream, instead of souring it, in the usual troublesome and tedious manner. The cream, as it is skimmed, is put into a vessel, un-
 enough is collected for churning, and kept in any convenient place where it will not freeze. It is then poured into a copper or brass kettle, and hung over the fire until scalding hot, but is not suffered to boil—it is then poured back again into the cream pot, and left to stand till evening, which time it will be nearly cool, rather older than new milk; it is then churned, and thus, has never failed to produce good butter a very short time; and of a better quality and color than when soured in the usual way. Indeed it is scarcely any more trouble to make butter in this way in winter, than in the usual mode in summer. Care, however, must be taken that the fire be not too strong, as, if the cream should be in the least burnt, it will give it an unpleasant taste."

The making of butter from scalded cream has long been practiced in England. (See No. 2, page 12 of the E. Farmer.) Mixing one quart of boiling water with every eight quarts of milk, as recommended in Hunter's Geographical Essays, (see No. 16, page 123) would probably facilitate churning as well as deprive the milk of any disagreeable taste resulting from the cows having been fed on turnips. But when brass or copper vessels are used for scalding milk or cream, care must be taken to keep them perfectly clean, and not scald sour milk or cream in them, nor even to let sweet milk or cream stand in them to cool, lest the acids become in some degree impregnated with ver-
 grease, which they acquire from the metal. Sweet milk or cream, while hot will have no effect on brass or copper, but when cool, will corrode [oxidize] those metals, and become more or less poisonous. Milk and cream when sour, either cold or hot, will corrode brass or copper vessels, and become more or less poisonous.—

Ed. N. E. Farmer.

From the Farmers' Weekly Messenger.

A WORD TO A THINKING FARMER.

A common sap, wooden hooped cider barrel costs 33 cents, and by hooping it once, (which will cost 40 cents) it will last four years; after which it is generally unfit to put liquor in. A white oak, iron bound hogshead can be had new, heart stuff, well painted, to hold about three barrels and a half, for \$5.—This will require to be smeared over with some kind of refuse oil, with a little Spanish brown and lamp black in it, once in three years, (which may be done at some leisure time, such as a rainy day,) and it will then last a man's life time. I am told that there are people in the state of Maine who

have had casks of this description in their possession, in constant use, for upwards of fifty years, which now appear as good as new.—Heart stuff barrels are to be found in every part of our country from twenty to thirty years old, which have never been painted at all. Is it not truly surprising, when these facts are so well known, that any farmer should purchase sap barrels to put liquor in, at any price? From the best information which I am able to get I believe it will be found that the expense of keeping casks to keep twenty barrels of cider in, will be one year with another, reckoning every expense, nearly as follows:

To keeping twenty barrels of cider in barrels with wooden hoops,	\$8,50
To ditto ditto in heart stuff barrels with wood hoops and not painted,	4,50
To ditto ditto in heart stuff barrels with iron hoops, painted,	3,00
To ditto ditto with iron bound hogsheads, painted,	2,50

When it is considered that cider is so much better by being kept in hogsheads than in barrels, it is evidently much cheaper to keep cider in hogsheads than in sap barrels, at even a quarter their present cost.

It is true large timber is becoming an article of so much importance that hogshead staves are in many places very difficult to be got; but staves of heart stuff that will make casks which will hold sixty gallons can be had almost any where: and I should think that the most incredulous person will find by inquiry that iron bound casks with thick staves, to hold as much as he can well get them, if they are kept well housed and painted, will produce a clear saving of from two to four hundred per cent. Many of our heart stuff casks are, however, very poor, owing to the staves being so thin. The rum hogsheads we get of merchants are often risky to purchase, as there are generally some sap staves in most hogsheads, and they are often injured by being strained at sea. If farmers can save twenty or even ten per cent. in any branch of husbandry, they ought to be attentive to it; for in agriculture, as well as in religion, "he that disregardeth small things shall fall by little and little." A.

THE TREADING MILL.

We have visited this new, and we doubt not powerful machine, in the reformation of vice, and prevention as well as punishment of crime. It is erected in a building provided for the purpose, at the Penitentiary establishment, and consists of two long wheels, turning like a squirrel's rolling cage, only that the weight is applied outside instead of inside of the bar or steps. Each wheel is long enough for sixteen persons to stand upon it together, supported by a hand-rail, shifting their feet with short and quick steps, to prevent being without support by the foothold rolling inwards from under them. A screen separates the two wheels, each of which, interlocked by ordinary machinery with each other, is moved by the weight or specific gravity of 16 persons, and the whole force applied, in an adjoining apartment, to the movement of two pair of mill-stones, which grind the usual quantity produced by the amount of power.—Each wheel is attended by thirty-two persons (one by males and the other by females) one

half of whom are employed in exercise or labor, while the others are at rest; at the sound of a bell, striking about once each half minute, the person at one end of the wheel stepping off, the remainder moving down, and another stepping on at the head. Thus each person is employed eight hours a day, alternately in exercise and rest, eight minutes at each interval, from eight in the morning to four in the afternoon. The effect of this discipline, it is believed, will be of the most salutary and unequivocal nature. Although the employment at first appears light and easy, it is already found by experience, probably from its unremitted regularity, in itself the dread of the idle and profligate, to have a serious and lasting effect on its subjects. The prisoners are daily complaining of indisposition or fatigue, and taken from the wheels by direction of the physician. A register is kept of their services; and but very few, if any, it is confidently expected, after being once discharged from this cage, will merit a return to the Treading Mill.

A SHORT STORY.

As told by Mr. Matthews, the Comedian.

"My friend and myself, when in Devonshire, were visiting an acquaintance, who had a daughter not remarkable either for her wit, beauty, or accomplishments. She had passed the grand climacteric, and was certainly on the wane; her heart had lost none of its susceptibility to *le grand passion*. She had for ten years been conspicuous for her dress, airs, and "bea-
 catchers;" but alas! she had toiled all night at balls, routs, and levees, but had caught no beau. Being as vain as she was simple, we thought her fair game for a quiz. Miss Lucretia Elvira, said I, have you heard of the late act of parliament, by which all ladies with *small mouths* shall be allowed to marry two husbands? "No, Sir," said she, (SCREWING UP HER MOUTH INTO A PUCKER)—what a *curis* law!" You are wrong, Edward, said my friend to me; those ladies with *large mouths* are to be allowed two husbands. "LAW ME!" exclaimed she, (opening her mouth as *big as a bucket*), "what a *eu-ri-ous* law!"

MISERIES OF EDITORS.

The following catalogue of editorial grievances is from the new editor of the Nantucket Inquirer:

"We are often-times forced to unravel hieroglyphics, that would puzzle an Egyptian necromancer;—to decypher *chirography* which is more like *cryptography*, and resembles a Mosaic MS. rather than any post-diluvian production;—to transpose the idioms of all languages into that of our mother tongue, as well as we know how;—to affix *punctuation* to things that came to us without *point* or *character*. We have *prose* to translate, wherein the first letter of every line is an obstinate Capital;—and *poetry* to measure and *versify*, in which the capitals stand up in thick array, like scare-crows in a pea-patch, or 'sheep's bones round a parsley bed.'"

A man of an agreeable and merry disposition, but very poor, finding one night, some thieves in his house, told them, without putting himself in a passion, I cannot imagine what you expect to find in my house in the night, when I can find nothing in it in the day time

Although we believe the following was dictated by honorable feelings, and that the writer in originating the production was merely solicitous that honor should be given where honor is due, we cannot think that there was any *adulation* in the gentlemen who made and drank the toast, which it seems has given offence, to wound any person's feelings, or to overlook the merits of the Berkshire Agricultural Society. In a moment of conviviality, it cannot be expected that the scale of justice will always be held with a *steady* hand, and if merit should happen to kick the beam it should be overlooked as an occurrence, which if not justified, is perhaps palliated by circumstances. We do not perceive that the Hon. Mr. Welles's reply, and the toast he gave in answer to that of the Worcester gentlemen can in any degree impute blame. Common civility required a reply, and it would hardly have been proper for Mr. Welles to have said that the compliment contained in the toast was misapplied. Still, as we said before, we appreciate the motives of our respected correspondent, and, perhaps our views of the subject are incorrect—besides *non est nobis tantus compere litis*. It does not belong to us to settle the dispute—but we wish it settled.

TO THE EDITOR OF THE NEW ENGLAND FARMER.

We have taken pleasure in reading the details of the proceedings of Agricultural Societies the past season in your valuable paper. The proceedings of the Worcester County Agricultural Society have attracted our attention. We rejoice at the successful efforts and displays of this Society, and we admire their zeal in this greatest and best of all causes. We are not disposed to abridge them of the pleasure of general admiration, nor debar them of courting the approbation of other Societies, if not done at the expence of truth and justice. We however cannot greatly profess ourselves to admire or approve of the following toast, given on that occasion, and echoed by a member of the Massachusetts Society.

"The Massachusetts Agricultural Society—The soul which animated 'the Heart,' and which is infusing life into the extremities of the Commonwealth."

If we were to remain silent on this occasion, it would be construed into an high degree of insensibility and want of attention to the well founded fame of another Society in this State, to which the sentiment of the toast could apply with truth and without cause of offence. That the Worcester Society should have courted a compliment, at this very recent state of its existence, is no subject of wonder, but that the Hon. Mr. Welles, who became the organ of the compliment, and was a Trustee of the Massachusetts Society, should have forgotten the honorable distinction heretofore awarded to the Berkshire Association, and placed on their annals, is indeed a wonder.

It is not our object to provoke any collision or inauspicious rivalries among citizens and societies devoted to the same great and useful pursuits—nor are we in the least disposed to detract from the distinguished merits and valuable efforts which characterize the Massachusetts Agricultural Society. But we are disposed to think, that exact and equal justice to men in all their relations to society is the most honorable and useful course, and the least liable to produce dissatisfaction and opposition. The truth is, much caution and delicacy is requisite to conciliate good feelings among Societies which are much excited, and by whom great ardor is

displayed in the pursuit. On this subject we quote the sage and timely counsels of the venerable President Adams, formerly President of the Massachusetts Society, in a letter of August 11, 1812, to a friend in Berkshire. "You may depend upon it, your Berkshire Agricultural Society, and our Massachusetts Society for Promoting Agriculture will assuredly quarrel and go to war unless both are managed with great prudence, delicacy, caution and circumspection. *Sat verbum*. How is it, that agriculture and commerce are rivals in France, England, Holland? and what tremendous consequences have resulted from those rivalries, the history of mankind will shew." Whenever the Massachusetts Society, or any other Society for her, shall assume the merit of being "the soul which animates, the heart which is infusing life into the extremities of the state,"—the Berkshire Society will interpose her veto to that assumption, founded on the following facts. What was the state of the Massachusetts Society previous to 1811, when the Berkshire Association commenced its successful career? Had that Society infused any life or animation in the promotion of agriculture in its immediate sphere of action, much less to the distant extremities of the State, sufficient to divest themselves of the proffered annual premiums? Previous to the existence of the Berkshire Association, was the Massachusetts Society of *any practical utility*? And what were the fruits of a band of Patriots, who from the best of motives sustained their measures, previous to 1816, when they held their first exhibition at Brighton, *following the footsteps of the Berkshire Society*, other than the production of an annual volume on agriculture, which was little known and less regarded?—That this question may be settled forever, and we charitably hope satisfactorily, we will appeal to the best authority, that of the Massachusetts Society. What the effects of the example and efforts of the Berkshire Society subsequent to 1815, not only on this State, but the Nation, were, we do appeal triumphantly to the following extract from the address of the Hon. John Lowell, at the first exhibition at Brighton, in 1816:—"The Berkshire Society, though comparatively in its infancy, and restricted in its means, had with a vigor and intelligence which did it the highest credit, taken the lead in establishing exhibitions of this nature, which has been productive of great emulation, of improvements in agriculture." "It is our pride to acknowledge that we follow the footsteps of a younger Society, thus evincing that we are ready freely to acknowledge merit, wherever it may be found."

Upon this evidence we rest the decision, whether the reverse of the toast is not the truth—that the Berkshire Association was *the soul which animated, and the heart which infused life not only into the Massachusetts Society, but the State and Nation*. Anxious to be useful, to be the channel for diffusing the richest blessing to our country, the Berkshire Society pursue their objects with unabated diligence, and only desire that New England, nor the United States will ever permit themselves to forget the *origin of a system*, which has produced to general and increasing good. To our friends in Worcester, and every where, we would say, that the high spirit and conscious dignity of Berkshire, will never suffer to pass unnoticed any attempts to

detract from their just and well sustained claim at originality and usefulness in their agricultural system.

A Member of the Berkshire Agricultural Society

FACTS AND OBSERVATIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY

FOR THE NEW ENGLAND FARMER.

SAGACIOUS BREED OF CATTLE.

In the Hottentot districts of the Cape of Good Hope the natives not only use their bison-oxer which are of good size, for the saddle and draught, but train them to war. These cattle being assembled in troops, with a Hottentot army, on a given signal, rush upon the enemy with great fury, goring with their horns, trampling with their feet, and overturning every obstacle which opposes them. Individuals of them are also set to watch the flocks and herds, in the manner of shepherd's dogs, which they faithfully perform like the dog, distinguishing friend from enemies, caressing the former, and attacking the latter with the utmost rage.

A RACE-OX; AND NEAT CATTLE FOR THE SADDLE.

Some years ago a Sussex [English] ox ran four miles over Lewis' Course, for a hundred guineas, which he performed after the rate of fifteen miles per hour.—In India, *travelling oxen* are curried, clothed, and attended with a much solicitude, and much greater kindness than we bestow on our best horses. The Indian cattle are extremely docile, and quick of perception, patient and kind; like the horse their chief travelling gait is a trot, and it is said they often perform journeys of sixty successive days, at the rate of thirty to forty-five miles a day.

IMPROVEMENT IN THE BREED OF CATTLE.

The formation of an entire new breed, in the establishment of a permanent variety is a matter requiring the most diligent attention, through a long course. For that reason it is commonly the shortest and safest method to part entirely with an inferior stock, or such as requires much amendment, and to replace with a species the nearest to perfection even at a high price.

The following remarks on the subject are from Messrs. Wells & Lilly's edition of Deane's New England Farmer, under the article "BULL."

"It was formerly believed that a frequent change of animals, from one country, or one section of a country, to another, was indispensable to the preservation of a pure and excellent breed of cattle, but this idea is almost exploded. Bakewell, Princeps, and other noted graziers and raisers of stock in England have proved, that it is by careful selection of individuals of good forms and properties, that a race of cattle can be best improved. The system of 'breeding in and in,' which confines the improved races or animals to their own families, is now much more in fashion, and the success of the British graziers, and the best experience of our own country seem to justify the opinion. Importations of the best animals of Great Britain have been made, it is true, and they have essentially and manifestly improved our stock. But this does not disprove the utility of 'breeding in and in,' because these excellent imported animals were produced, and brought to their present perfection by the principle of selection from

the same excellent stock. And when imported here, the principle of "breeding in and in," or preserving the stock has been scrupulously adhered to, with highly beneficial effects.

"Before we quit this article, it may be adduced as a proof of the soundness of the modern doctrine, as opposed to the old practice of *crossing* the breeds constantly, that, as to horses, the interest in which is much greater in some countries on account of the rage for the pleasures of the chace and of the turf, it is an established law, that the race should be kept pure, and the pedigree of a race-horse is as accurately preserved as that of a line of kings."

It appears that the pedigrees of certain breeds of cattle have been preserved in Great Britain of late years with all possible care, and the same practice is not without precedent in the United States. See No. 17—page 134 of the New England Farmer.

COWS SHOULD NOT BE EXHAUSTED BY MILKING.

The cow which is desired to remain in perfection, either for milking or breeding, should not be exhausted by drawing her milk too long after she becomes heavy with calf, it is to pay too dear for a present supply of milk. She should be suffered to go dry, at least, two months before calving.

ON THE IMPORTANCE OF PROCURING A GOOD BREED OF COWS.

The expense of keeping cows of a poor breed is as great and sometimes greater than that of keeping the best. If cows are poorly kept, the difference in breeds will scarcely be discernible by the product in milk. Some have, therefore, supposed that it is the food alone, which makes the odds in the quantity and quality of milk.—This supposition is very incorrect, as may be evinced by feeding two cows of a similar age, size, &c. on the same food, the one of a good breed for milk, and the other of a different kind, and observing the difference in the milk product. No farmer unless he is very rich can afford to keep poor milch cows. He might almost as well keep a breed of "naked sheep," such as Swift tells of in his Gulliver's Travels. The farmer who raises a heifer calf, that is from a poor milker, of a bad or mongrel breed, is as foolish as he would be, if in clearing land he should burn on the ground the birch, maple and walnut, and save white pine and hemlock for fire wood. And yet many farmers sell the heifer calves of the best milch cows to the butchers, because they are the fattest. Such folks deserve to be poor, and may expect to meet with their deserts.

COWS WHICH GIVE THE GREATEST QUANTITY OF THIN MILK, THE MOST PROPER FOR SUCKLING CALVES.

Those cows which give the greatest quantity of milk are the most profitable for suckling calves, for rich milk is said to be not so proper food for calves as milk which is less valuable for dairy purposes. Milk which contains a large proportion of cream is apt to clog the stomachs of calves; obstruction puts a stop to their thriving, and sometimes proves fatal. For this reason it is best that calves should be fed with the milk which first comes from the cow, which is not so rich as that which is last drawn.

DIFFERENCE IN THE MILK OF COWS.

Dr. Anderson relates that a friend of his, who

kept only a single cow for the use of his own family, bought one from a person who kept from fifteen to twenty cows, chiefly for the purpose of rearing calves, but in part for the dairy. This cow was recommended as one, which gave a large quantity of milk for her size, and her milk was said to be of an excellent quality.—

This last was a circumstance of great consequence to the gentleman, who proposed to buy the cow, who therefore took care to taste the milk and found it to be apparently very good. But although the milk was thick and rich to the taste it never could be brought to yield an atom of butter, though every method, which could be devised, was tried for that purpose. This cow had given milk for three seasons before she was sold, without its having been discovered that her milk did not give as much butter as that of any other cow. This experiment proves that there may be individual cows which yield milk of qualities different from that which the eye and the taste would seem to indicate. It would therefore be well for every person, who wishes to superintend a dairy with a proper attention to economy, always to ascertain the qualities of the milk of every cow individually, as soon as she is turned into the dairy; otherwise he may proceed for years without knowing that he is subjecting himself to a great expence without deriving any advantage from it. It may likewise happen, that from casual disease, or other circumstances the milk of the cow may become tainted at a particular time with a peculiar taste or other quality, which may greatly injure the whole stock if it be mixed with it, and occasion loss to the owner. It is, therefore, recommended, as an invariable practice in every dairy, to keep each cow's milk separate, on the first day of the month, at least, throughout the year, for the purpose of ascertaining the quantity and quality of the milk yielded by every cow individually. Were this practice strictly adhered to, it would advance the practical knowledge of the dairy more in the space of one year, than can be done in the random mode usually adopted in a century.

CALVES SHOULD HAVE ROOM, LIGHT AND AIR.

An English writer of high authority, says "I have heard and read much of calf-coops for calves which were fattening, where the animals had no room for turning themselves, and where the light is excluded; but I have no conception of the necessity of such measures in order to make good veal. I have made, with despatch, as good and as fat veal, as Leadenhall market can exhibit, in common pens without the smallest obligation to any of the aforesaid extraordinary precautions, which, in truth, I disapprove, as equally probable to induce disease as to accelerate the fattening of calves." It has been recommended to cram hogs and poultry also in dark and confined places without allowing the poor animals either light, fresh air, or exercise. But these should seem requisite for health in the animals, and the meat of unhealthy ones would not seem to be a very wholesome article of diet.

REMEDY FOR POISON BY THE OXIDES* OF LEAD OR COPPER.

As the oxides of lead are poisonous, when ta-

ken into the stomach, it ought to be generally known that these oxides, even in a state of solution, as well as the oxides of copper, may be rendered innoxious, by the exhibition of a large dose of common sugar, or sirup.—See Dr. Ure's Chemical Dictionary.

WINE TESTS, OR METHODS OF ASCERTAINING WHETHER THERE BE ANY LEAD IN WINE OR CIDER.

We are told that fraudulent wine merchants have sweetened their wines and ciders by the addition of lead. Dr. Watson relates that it was at one time a common practice at Paris. He directs how it may be detected—Chemical Essays, vol. III. page 369. Methods of detecting this and other adulterations of wine may also be seen in Dr. Willich's Lectures on Diet and Regimen, pages 357 to 362. The following is easy of application, and will be found effectual: Equal parts of oyster shells and sulphur may be heated together, kept in a white heat for 15 minutes, and when cold, mixed with an equal quantity of cream of tartar: These are put into a strong bottle with common water to boil for an hour; and then decanted into ounce phials, adding 20 drops of muriatic acid to each. This liquor precipitates the least quantity of lead, copper, &c. from wines, in a very sensible black precipitate. As iron might accidentally be contained in the same wine, the muriatic acid is added to prevent its precipitation, and its being mistaken for the precipitate of lead.

FARMER'S ACCOUNTS.

Regular accounts, says a celebrated agriculturist, are not so common among farmers as they ought to be, and in this respect, persons employed in other professions, are much more attentive and correct. The accounts of a farmer, occupying even a large estate, and consequently employing a great capital, are seldom deemed of sufficient importance to merit a share of attention, equal to that bestowed by a tradesman, on a concern of not one twentieth part of the value. There is certainly some difficulty in keeping accurate accounts respecting the profit and loss of so uncertain and complicated a business as the one carried on by a farmer, which depends so much on the weather, the state of markets, and other circumstances not under his control; but the great bulk of farming transactions is settled at the moment, that is to say, the article is delivered, and the money at once paid; so that little more is necessary than to record these properly. In regard to expenses laid out on the farm, an accurate account of them is perfectly practicable, and ought to be kept by every prudent and industrious farmer.

The advantage to be derived from regular accounts, cannot be doubted. By examining them, a farmer is enabled to ascertain the nature and the extent of the expense he has incurred, in the various operations of agriculture; and to discover what particular measures, or what general system contributes to profit, or occasions loss. The principle of economy may thus be introduced into the management of a farm; and the lessening of expense effected, which is every day becoming of greater importance, bearing a higher proportion to the produce of the farm.

* An oxide is a metal combined with oxygen [vital air] extracted either from the atmosphere [when it is called rust] or from some acid substance, such as vinegar, sour milk, cider, wine, &c.

In order to facilitate the adoption of so useful a plan as the keeping of regular accounts, it would be of use that not only memorandum books, for the transactions of the day, but account books were properly arranged, and divided into columns, containing every head, which experience in the business of farming may suggest, together with a broader column for general observations. The accounts of gentlemen farmers, or of the bailiffs they employ cannot be too minute; but in regard to common farmers, the great objects are to have them short and distinct.

It is proper to add that to record pecuniary transactions is not the only object to be attended to in the accounts of a farmer. It is necessary to have an annual account of the live stock, and of their value at the time; of the quantity of hay consumed; of the grain in store, or in the stack yard; and of the implements and other articles in which the capital is invested. An account detailing the expense and return of each field, according to its productive contents is likewise essential, without which it is impossible to calculate the advantages of different rotations; the most beneficial mode of managing the farm; or the improvements of which it is susceptible.

FOR THE NEW ENGLAND FARMER.

Mr. Editor—I have for several years past, and more frequently of late on the margin of the Blue Hills and in other retired spots, had the gratification to observe a bird of most beautiful plumage, which, though coy and disposed to solitude, I sufficiently noted to find very distinctly described in the admirable work of our countryman, "Wilson's Ornithology." This description I have abridged and now send you for publication. 'Thou' your paper is very properly and usefully devoted to agriculture—yet whatever gives a splendor to the scenery of the country and is not *merely* harmless, but useful to the cultivator of the soil—cannot be said to be out of place in your pages. It will be perceived that this showy stranger, which is induced more and more to visit us of late, mostly feeds upon the large winged and most noxious and injurious insects. If, however, this bird, so modest and sweetly attired, is not kindly received, we shall lose the visits with which he gratifies us. Why not place him with the Swallow, the Turtle Dove, and other favored harmless birds, who in fond reliance cluster about our houses? But above all, let those who deal out leaden death, consider that as this sweet bird of both song and plumage affords no inducement as game or luxury for food—whether it does not belong to their spirit and gallantry to spare as they wish to be thought *its* admirers, *innocence and beauty*.

W.

THE SCARLET Tanager.

This is one of the most showy birds which regularly visits us from the south in the spring of the year, dressed in the richest scarlet, and set off with the most jetty black. He rarely approaches the habitations of man, though he sometimes is seen in the orchards in search of food. The depth of the woods is his favorite abode, where, amongst the thick foliage, his simple notes may be heard, which appear to proceed from a distance, though the bird should be near to you; a faculty no doubt intended by the kind Author of nature to secure him from the danger to which his glowing color would expose him. His nest is slightly built on the horizontal branch of a tree; the eggs are three, of a pale blue color, spotted with brown and purple; they rarely raise more than one brood in a season, and leave us for the south in the last of August. His principal food is large winged insects, such as wasps, hornets, and humble bees, and fruit, particularly the whortleberry,

which in their season form almost his whole fare. The male of this species is rather less than the robin; its plumage a most brilliant scarlet, except the wings and tail, which are of a deep black; the bill curved and of a yellowish color; the legs and feet light blue. The female is green above, and yellow below; the wings and tail a brownish black, edged with green. The young birds, during their residence here, continue nearly of the same color with the female.

Amongst all the birds which inhabit our woods, there is none that strikes the eye with so much brilliancy, when seen among the green leaves with the light falling strongly on his plumage, as this does. His manners are modest and inoffensive. He commits no depredations on the property of the husbandman, but rather benefits him by the daily destruction of many noxious insects; and when winter approaches he seeks in a distant country the sustenance which the severity of the season denies to his industry in this. He is a striking ornament to our rural scenery, and none of the meanest of its songsters.

Such being the true traits of his character, we should always with pleasure give a safe reception and welcome to this beautiful inoffensive stranger in our orchards, groves and forests.

THE FARMER.

BOSTON:—SATURDAY, DEC. 14, 1832.

ON LAYING DOWN LAND TO GRASS.

It has been said by some writers that a farmer ought never to sow grass seeds with any kind of grain, but in all cases to sow it by itself; which, it is affirmed, will always do more than repay the loss that is sustained by the want of a crop of grain. Dr. Anderson and some other writers, however, condemn that practice, and observe, in substance, that if we were to have regard to no other circumstance but the grass crop alone, it will always be best to sow it with some kind of grain; but when we consider likewise the loss that the farmer sustains for want of a crop of grain, the practice recommended of sowing grass seed alone must be looked on as highly pernicious.

When grass seeds are sown with grain the latter grows quickly and prevents the growth of annual weeds, while it shades the tender plants of grass from the direct rays of the sun, and preserves the earth in a proper degree of moisture, so as to nurse the tender grass in the most kindly manner. The grain decaying after the grass is well rooted and can bear the heat and drought, the grass obtains as much air as is necessary.

Though ground is not often too rich to bear a good crop of grass, yet, sometimes it may be too highly manured to produce a good crop of grain. In this case, it may be prudent to forego the hope of a crop of grain, but not to omit sowing the seeds of some kind of grain with the grass seeds. Grain should, where the land is very rich, be sown thinly over the field, and will help to bring forward the grass in a kindly manner, and in the season proves dry, the farmer may thus obtain a very great crop. But, if the season is rainy, or the crop from any other cause too luxuriant, whenever the grain or the grass begin to lodge, so as to be in danger of rotting, it should all be cut immediately, and employed as a green fodder for cattle or made into hay. The extraordinary quantity of fodder procured in this way, will more than indemnify for the price of the seed of the grain; as the farmer may thus procure two full crops of succulent fodder in one season.

Autumnal sowing of grass seed is not approved of by good writers. The spring of the year is preferred as less precarious, although fall sowing will sometimes answer.

The mould of the ground, which is laid down to grass, should be made very fine, as the seeds, being very small, may otherwise be covered too deep, by falling below, or be scorched by lying above great clods. Like other seeds, they require a due degree of moisture to cause them to vegetate, and therefore should not be left exposed to the rays of the sun without being covered; for unless rainy weather follows immediately after sowing, many of the seeds will not vegetate. On this account it is always well to harrow the ground immediately after sowing with a light close-toothed harrow, which should be kept for that purpose; and sometimes a gentle rolling is of use after that, especially upon light spongy ground. But no one circumstance so effectually ensures the vegetating of these small seeds as sowing them as soon as possible after the ground is ploughed, while the soil remains moist. It is always good economy to lay down rich, and not poor ground to grass.

It is asserted in the Memoirs of the New York Board of Agriculture, that "grass seeds take remarkably well with buck wheat. Three pecks of buck wheat per acre may be sown, and the grass seeds harrowed in with it; the whole should be neatly rolled, and a smooth surface left; as buck wheat sown at this season will not go to seed to advantage, part of the crop, when in full blossom, should be cut daily, as green food for working horses and cattle."

Rees' Cyclopedia, under the articles "Grass," and "Laying-down to Grass," gives very copious and minute directions on this subject, of some of which we shall avail ourselves, and others are either well known to our practical agriculturists, not well adapted to our soil and climate, or in substance comprehended in what we have written. "It is better that the lands intended for grass, especially when they are intended to be kept in a permanent state of sward, should incline, in some measure, to moisture; light, thin, dry descriptions of soil are better suited for the production of grain. The most usual period of putting in grass seeds has been the spring, at the time the grain crops are sown; but where the land has been brought to a suitable state of preparation, by means of green and other fallow crops, the latter end of the summer, as about August, has been the more general time. In the former case they are most commonly put in with the grain crops; but in the latter without any other sorts of crops." On this subject there appears to have been a great diversity of opinion, but on the whole it seems to be the belief of the best agriculturists that grass seeds answer almost equally well in either method. "Where the land is in a proper state of preparation and tillage, if sown with oats, they will be apt to become so luxuriant as to greatly injure, if not wholly destroy, the young grass-plants, by the closeness of their shade. In some cases, however, they succeed tolerably well with this sort of crop." "The practice of employing bush harrows is improper, as in that way the seeds are liable to be drawn into lumps."

Sir John Sinclair observes that "the manner of sowing grass seed requires to be particularly attended to. Machines have been invented for that purpose, which answer well, but they are unfortunately too expensive for the generality of farmers. It is a bad system to mix seeds of different plants before sowing them, in order to have the fewer casts. It is better to sow each sort separately, as the expense of going several times over the ground is nothing compared to the benefit of having each sort equally distributed. The seeds of

grasses, being so light, ought never to be sown in a windy day, except by machinery, an equal delivery being a point of great consequence. Wet weather ought likewise to be avoided, as the least degree of soaking is injurious.

"When the grain is carried off, the young crop of grass should be but little fed during autumn; but heavily rolled in the following spring, in order to press the soil home to the roots."

Red Clover is more used in New England in laying and down to grass, perhaps, than any other grass. The author of a valuable work, published not long since in Albany, entitled "A Treatise on Agriculture" directs ten or twelve pounds of clover seed to be sown on an acre, if the soil be rich, and double the quantity if it be poor. He condemns the practice of mixing the seeds of timothy (herd's grass of New England) and rye, grass, &c. with those of clover, "because these grasses neither rise nor ripen at the same time. Another practice, equally bad, is that of sowing clover seed on winter grain, before the earth has acquired a temperature favorable to vegetation, and when there can be no doubt but that two thirds of the seed will perish." This writer is likewise of opinion that clover should not be pastured the first year, and observes, that "if the *crowns* of young clover plants be nibbled, or otherwise wounded, the roots die. Sheep and horses (both of which bite closely) should, therefore, be particularly excluded from clover, unless intended for pasturage only."

The best European cultivators allow from fifteen to twenty pounds of clover seed to an acre. By this mode of sowing it grows less rank, lodges less, and is more profitable for making hay, or soiling. They likewise recommend sowing this grass in the spring, even when the grain with which it is to grow has been sowed the fall preceding. They advise harrowing the clover in, when it has been sowed under these circumstances, and assure us that the harrowing will not injure the grain, but rather be of service to it.*

If the land be moist and rich, herd's grass, alias timothy grass, alias meadow cat's tail, is, perhaps, better to lay it down with than clover. It requires about ten or dozen quarts of seed to an acre. This grass succeeds better in the northern than in the southern parts of the United States. We believe farmers in general in New England, unless the soil is dry, light and sandy, prefer mixing clover with timothy seeds, in laying their lands down to grass, allowing more or less timothy in proportion to the moisture of the soil. And, notwithstanding the respectable authority of the Albany writer, adverted to above, we are not prepared to condemn this practice. The timothy has a tendency to prevent the clover from lodging; clover is more easily made into hay when mixed with that grass, and the mixture forms a food, which appears to be more agreeable to neat cattle than either of those grasses separately.

Some English writers advise, when convenient, to pasture land, which has been recently laid down to grass from three to six years, without mowing it. It will afford more feed, than if it had been mowed a year or two, and will not (as our farmers express it) bind out so soon; that is the grass roots will not, so soon, become so matted together as to prevent the growth of the plants, and require breaking up, in order to render it productive.

*See Messrs. Wells & Lilly's edition of Deane's New England Farmer, article "Clover."

Senna.—The Editor of the American Farmer states that he has received a small parcel of Senna seeds from Wm. Cattell, Esq. of Charleston, S. C. which has been cultivated and found to possess the virtues of the imported Senna.

Great Crop of Mangel Wurtzell.—The last American Farmer contains certificates, which prove that John Hare Powell, Esq. raised nine hundred and eighty-two and an half bushels of Mangel Wurtzell roots, closely cut beneath the crowns and free from dirt, on one hundred and fifty-five and a quarter square perches, less than an acre of ground. The crop was estimated by the Editor of the American Farmer, from one load's being weighed, to weigh 45,750 pounds, of clean trimmed roots.

FARMER SUMMARY OF NEWS.

Congress, and the President's Message.—The second session of the seventeenth Congress commenced on the 3d inst. The Message of the President was received, read, and 3000 copies, together with the documents, ordered to be printed. The message commences with a favorable view of the political system of the United States, which will not call for augmented cares, but states that other causes exist which are highly interesting as well to the United States as to the whole civilized world. It gives a pleasing view of our commercial relations with France and Great Britain—States that his Imperial Majesty the Emperor of Russia on the question submitted to him by the United States and Great Britain, concerning the construction of an article of the Treaty of Ghent, has been received, and that a convention has since been concluded between the parties, under the mediation of his Imperial Majesty, to prescribe the mode of carrying the article into effect, in conformity to the decision—It informs that a Territorial Government has been established in Florida—That the fiscal operations of the year have been more successful than was anticipated at the commencement of the last session of Congress, and that there is now a surplus in the treasury, and a greater one is anticipated—It commends the organization of the United States' Army—Speaks highly of the Military Academy—Remarks on piracy of the West Indies as of a recent date, and of the efforts of the U. States to suppress it—States that a serious malady has deprived us of many valuable citizens at Pensacola, and checked the progress of some of those arrangements which are important to the territory—That the Lead Mines require an agent skilled in mineralogy—That the Cumberland road needs repairs—That our manufactures have increased and are increasing—It gives a concise view of the aspect exhibited by foreign nations, which shows that the U. S. as a member of the great community of nations have rights to maintain, duties to perform, and dangers to encounter—The situation of Spain and the Independent Governments south of the U. S. is concisely adverted to—The situation of the Greeks is spoken of with feeling, "that such a country should have been overwhelmed, and so long hidden as it were from the world under a gloomy despotism;" but "a strong hope is entertained that these people will recover their independence, and resume their natural stations among the nations of the earth"—The effort which has been made in Spain and Portugal to improve the condition of the people is mentioned as consoling to all benevolent minds, and the President observes, that "when we see that a civil war of the most frightful character rages from the Adriatic to the Black Sea; that strong symptoms of war appear in other parts, proceeding from causes which, should it break out, may become general, and be of long duration; that the war still continues between Spain and the Independent Governments, her late Provinces, in this hemisphere; and that it is likewise menaced between Portugal and Brazil, in consequence of the attempt of the latter to dismember itself from the former; and that a system of piracy of great extent is maintained in the neighboring seas, which will require equal vigilance and decision to suppress it; the reasons for sustaining the attitude which we now hold, and for pushing forward all our measures of defence with the utmost vigor, appear to me to acquire new force."

Matthew St. Clair Clark, of Pennsylvania, has been chosen Clerk of the House of Representatives.

Mr. James Little, residing near Auburn, N. Y. was killed on the 16th ult. by his wagon overturning, and together with its contents falling on him.

Counterfeit \$10 bills of the Phoenix Bank, N. Y. and on the Bank of Troy, are said to be in circulation.

The Pirates.—Reports have reached us by an arrival here, and at Baltimore, that a British vessel of war has succeeded in capturing several pirates, in the neighborhood of Matanzas. A letter from Havana, of the 20th ultimo, received at Georgetown, confirms these accounts, and states that it was the Tyne Sloop of War that had a fight with the pirates in Lijuapo Bay, and took 29 prisoners. The Tyne lost 12 killed, besides wounded. The loss of the pirates was supposed to be 40 or 50. A piratical vessel lay off Havana on the 20th ultimo, which had threatened to capture the brig Lizabeth-Ann, bound to Philadelphia, even if he had to follow her to the Delaware.—N. Y. Merc. Adv.

The U. S. schooner Alligator was totally lost on the 19th Nov. on Carysford Reef—crew all saved.

Mr. Symmons Thrasher, of Attleborough, (Mass.) killed a hog on Friday last, which weighed 576 pounds. Mr. T. purchased this hog about a year since, when he was about four months old and weighed only 70 pounds.

A Mr. Clark, of Albany, has now in his possession a sow two years and seven months old, weighing 633 lbs.—two of her pigs 16 months old weighing, the one 635, the other 560 pounds, and a pig of nine months old whose weight is 490—the aggregate amount of weight of the family, 2,393.—N. Y. American.

Three large Oxen.—A few days ago three oxen passed through this city on their way to New York, which weighed, according to the patent scales of L. Bishop, Esq. as follows, to wit—3030—2570—2456. These oxen were raised and fattened by Col. Chapin, of Springfield, (Mass.) We are informed that a year or two ago Col. Chapin sold a pair of oxen in Boston for \$1050, neither of which weighed as much as the largest of the first mentioned oxen. It remains to be seen that the New Yorkers will be as liberal as the Bostonians.—About ten days since the mate of the largest of these three oxen died, and more than 300 pounds of rough tallow was taken out of him, exclusive of the kidney tallow.—New Haven Register.

Warning to Teamsters.—On Friday last, Mr. Michael Sweet, a respectable teamster, was precipitated by a sudden jolt from the tongue of his ox cart, the wheels of which passed over him, and besides injuring his scalp, fractured his right arm so badly, that amputation, it is feared, may become necessary. Let this unfortunate accident operate as a warning to teamsters not to sit upon the tongue of their wagons.—Providence American.

The Locomotive Gazette gives an account of a Panther's being killed by two dogs belonging to a person, who was in pursuit of wolves. The combat took place in the night, and was very obstinate.

Spontaneous Combustion occurred on the 29th ult. in the coal yard of Mr. Joseph Jamison, Baltimore. The fire occurred in a mass of coals, containing about five thousand bushels, and though apparently extinguished several times, it again broke out, and was the cause of successive alarms.

The Rochester, N. Y. papers inform that emigrants are conveyed on the Grand Canal, at the low rate of one cent a mile, and in proportion for furniture and effects.

We have been informed from a source that leaves us no reason to doubt the fact, that the society of Shakers at Canterbury in this state, have, within three weeks, sold TEN barrels of Cider in Boston, for which they received ONE HUNDRED DOLLARS in cash. Good common cider has been selling in this town for one dollar a barrel. Such is the difference between good, and very good!—Portsmouth Journal.

A cow may now be seen at Harrisburg (for 12 1-2 cents) upwards of 16 hands high, and supposed to weigh 1600 lbs. She was raised in Columbia County.—Penn. Correspondent.

An English horse, called Childers is said to have been the swiftest ever known, and has been known to have run near a mile in a minute. He cleared the course in New Market, which is only 400 yards short of four miles in 6 minutes and 40 seconds; running at the rate of 82 1-2 feet in a second. Eclipse is said to surpass him in strength, and to be but little inferior in swiftness.

DIED.—In Medford, Thursday morning, Rev. David Osgood, D. D. aged 75.—In this city, Isaac Rand, M. D. A. A. S. aged 80.

HEALTH.

The subject of my song is Health,
A good superior far to wealth.
Can the mind distrust its worth?
Consult the monarchs of the earth:
Imperial czars, and sultans, own
No gem so bright that decks their throne;
Each for this pearl his crown would quit,
And turn a rustic, or a cit.

Mark, tho' the blessing's lost with care,
'Tis not recover'd when you please,
Say not that gruels shall avail;
For salutary gruels fail:
Say not, Apollo's sons succeed;
Apollo's son is Egypt's* reed.
How fruitless the physician's skill,
How vain the pestilential pill.
The marble monuments proclaim;
The humbler turf confirms the same.
Prevention is the better cure;
So says the proverb, and 'tis sure.

Would you extend your narrow span,
And make the most of life you can;
Would you, when med'cines cannot save,
Descend with ease into the grave—
Calmly retire, like evening light,
And cheerful bid the world good night:
Let Temp'rance constantly preside;
Our best physician, friend, and guide:
Would you to wisdom make pretence,
Proud to be thought a man of sense:
Let Temp'rance (always friend to fame)
With steady hand direct your aim;
Or, like an archer in the dark,
Your random shaft will miss the mark:
For they who slight her golden rules,
In wisdom's volume stand for fools.

*In allusion to 2 Kings, xviii. 21.

FOR THE NEW ENGLAND FARMER.

There is a propensity existing in the minds of the most of mankind to resist the claims of those who appear to think that they deserve distinction, and profess to be candidates for renown. The best way therefore, to win applause is not to court it. Persevere in the path of rectitude, and if Fame follows you, very well, but never run after it.

Money laid out for the purpose of obtaining a high standing in society, or in other words for the sake of out-dashing and out-shining one's neighbors is generally thrown away. We live in an age, when splendid furniture, glittering equipage, and fine buildings are grown too common to attract much notice from spectators.

There is no life more fatiguing and perplexing than that of the subordinate votaries of fashion, who attempt to be *stylish* by dint of extravagant expenditure, and living beyond their income. Splendid indigence, finery and want, expensive but temporary shifts to support the appearance of plenty, when poverty oppresses and debt menaces are infinitely more distressing than open and avowed poverty.

A life well employed is an agreeable as well as an useful life; but "the pains and penalties of idleness" make existence a burden, which, in some instances has been found so insupportable that the wretched sufferer has sought refuge in suicide.

A man who has the appearance of order and economy in his family, who does not permit his sons to "hoe corn in silk breeches," nor to roll logs in ruffled shirts, nor to wear their best clothes on common occasions, nor suffer his daughters to make butter and cheese in chintzes and muslins, nor sweep the kitchen in silks and laces, will sooner be trusted and stand higher in the estimation of all sensible people than any other man of equal property, who sets up for gentility, with a family of smart sons and dashing daughters, the beaux and belles of the neighborhood, the former calculating to live on their wits, and the latter expecting to be maintained by their beauty, and all but worshipped for their accomplishments.

A more costly dress than the occasion requires, or the circumstances and station of the wearer can justify, are proofs not only of the extravagance, but of the *vulgarity* of the wearer. Many a would be fine lady and fine gentleman have thus made themselves ridiculous by the very means they made use of to attract admiration.—But parents, should, generally, permit their children to dress in a style somewhat similar to that of the young persons with whom they commonly associate; otherwise they will probably be ridiculed by their companions, which will make them feel undue inferiority, inspire them with envy, and spoil their dispositions.—Not that their clothes should be equally expensive, but their general appearance should be similar.

No man can be called great, merely in consequence of the station in which he is placed in society. The highest honors are but the pedestal, and merit is the statue erected upon it.

There is nothing more provoking than the condolence of a pretended friend, who appears to sympathize with you in your calamity, when you have reason to believe that in his heart he exults over your misfortunes.

Addison says that a dog has been the companion of man for more than 6000 years, and has learned of him only one of his vices—that is to worry his species, when he finds them in distress. Tie a tin canister to a dog's tail, and another will fall upon him—put a man in prison for debt, and another will lodge a detainer against him. This propensity to afflict the afflicted has given rise to the vulgar, but we fear correct adage "When a man is going down hill every one gives him a kick."

The man who is the most careful in examining facts, and the most accurate in authenticating them, will, in general, form the most correct conclusions; and him we call judicious. He who is the quickest in comparing and combining those which present themselves to him, and the most rapid in deducing conclusions is said to have talents. These two faculties are by no means necessarily conjoined; and thus it happens that men of talents are not always men of solid understanding.

The passion of De Lue, the natural philosopher, for music, was so predominant in his latter days, that a piano was placed by his bed side, on which his daughter played a great part of the day. The evening of his death, seeing her father ready to sink into a slumber, she asked him, "Shall I play any more?" "Keep playing," said he, "keep playing." He slept—but awoke no more.

ON THE USE OF LIME

Mixed with Gunpowder, in rending rocks and stones. By H. D. Griffith, Esquire, of Caerhun near Conway, North Wales.

From the letters and papers of the Bath and West of England Society.

Having been for some time in the habit of perusing your interesting papers on agriculture and other subjects, I am induced to lay before the Society a circumstance, which, though perhaps familiarly known to them, might, if more generally divulged through the channel of their publications, be of infinite advantage to the public.

In clearing my lands of the heaps of stone with which this country every where abounds, I found the quantity of gunpowder used in the operation to amount to a considerable sum at the end of the year; and as the price of this article has been increasing of late to an enormous amount, I had recourse to an expedient, by which the expense of it has been materially diminished.

I weighed out two pounds of gunpowder, and one pound of quick lime, well dried and pulverized; which, after having been thoroughly mixed with each other, I delivered it to the blaster, with directions to apply it, in similar quantities as he would have done the gunpowder by itself. I then selected six of the hardest granites I could find for the experiment; and the effects of the explosion were precisely the same as if gunpowder alone had been used. It now occurred to me, that this might be fallacious, and that a smaller proportion of gunpowder would produce the same effect as a larger; I accordingly ordered the man to bore holes in a similar number of stones, of the same texture and size with the former, and to put in a less quantity of gunpowder, by one third, than he would have done if it had been left to his own management. The stones were separated by the shock; but the difference in the effect was manifest to every person in the field; those with the mixture of lime and gunpowder having been much more effectually broken and shattered than the others.

After the success of this experiment, I have constantly adhered to the practice; and am so satisfied of its utility, that I wish to see it more generally adopted. One thing is certain, that a mixture composed of equal parts of quick-lime and gunpowder will *explode*; and, if this mixture were used merely as a tram of communication to the powder within the stone, what a national saving would it be in works carried on upon an extensive scale, such as the numerous quarries and mine works of this kingdom!

Swiftness of Men.—Men who are exercised in running outstrip horses, or at least hold their speed for a longer continuance; in a journey too, a man will walk down a horse; and after they have both continued to proceed for several days, the horse will be quite tired, and the man as fresh as in the beginning. The king's messengers of L-pahan who are runners by profession, go 100 miles in 11 hours.—Hottentots outstrip lions in the chase, and savages who hunt the elk, fire down and take it, are said to have performed a journey of three thousand and six hundred miles in less than six weeks.

Coles, in his excellent history of plants, notices the virtues of hemp thus laconically: "By this cordage ships are guided, bells are rung, beds are corded, and rogues are kept in awe."

NEW ENGLAND FARMER.

No. 21.

From the National Aegis.

MINERALOGICAL.....No. V.

That Science which renders no assistance to the industry of man, is unworthy of its association with the circle of those which multiply the means of human happiness, and that art which rests not on the broad foundation of scientific principle can never approach the limit of perfection. Constant practice, continued efforts, uninterrupted toil will work wonders. They give to their products, a polish, a neatness and an elegance which no other method can supply. But habit is always servile. It follows some example, it copies from some prototype, it pursues authority. Without the boldness of originality, or the daring of invention, it seldom strikes out for itself the path of improvement. The artist may be taught to unite the parts of complicated machinery, but his manual dexterity can never enable him to bring new powers into action, or avail himself of new mechanical agents. When the precepts of the master fail him, he is without a guide and at a stand. An acquaintance with nature and its laws, added to skill in imitation, would enable him to advance with certainty; and with the inducements to experiment, would give the assurances of success. From his connexion between the arts and sciences this mutual interchange of support, the advantage of theory is easily deduced. Not that false theory, which is the visionary fabric of the imagination, but the more substantial structure erected upon the firm basis of fact and observations. Insulated particulars divide and distract attention when existing separately; when collected under general heads, they form landmarks to determine the progress already made, and to point out the course in which to advance. He who records the experience of others, and goes through the process of generalizing, contributes more to the improvement of the earth, than one who holds the plough, or wields the sickle, without knowing a reason for his operations. Agriculture will not assume the rank to which it is so justly entitled, at the head of other professions, till it shall lean more upon science, and become less dependant upon imitation and precedent.

In an age when the acquisition of wealth is made the end of living, and profit adopted as the standard of utility, when the question what benefit is this, meets us at every step, it is necessary, in recommendation of any pursuit, to demonstrate its application to the common purposes of life. That this should be so, is but reasonable. Society has a claim upon all its members, to recompense the protection and the security which it extends. The existence which is spent in listless inactivity, is like the waveless calm of waters when no winds ruffle the surface. The expanse is clear and beautiful, but the sails of Commerce are not swelled, and the vessel is not wafted to the harbor. Selfishness may claim indulgence in following those objects which have solitary gratification in view, but men more liberal, will contribute to the good of others. Much satisfaction there may be in tracing the time worn letters of some mouldering coin, and taxing ingenuity to supply those which the eye

cannot discover, but there is more pleasure in watching the changes in the retort or the crucible, with the intention of aiding the cultivator of the earth, and lightening the burden of labor by the application of science. He that employs whole years in decyphering an inscription which perhaps has no local habitation but in his own fancy, and no name other than that his enthusiasm bestows, is less valuable in society than the mineralogist who pores upon the angles of a crystal or contemplates the structure of rocks, and examines the formation of the globe, that he may communicate the secret of its treasures or unfold the nature of its soils.

Yet Mineralogy has much that can interest him, who seeks only the employment of the hours of leisure. The beauty, the richness and the extent of its objects cannot be exceeded by the subjects of any other department of science. The flowers which open in the beams of morning, fade in the noon day heat. The Oak, which outlives whole generations falls and decays. But the rocks, the hills, the mountains endure. The footsteps of Men, were printed upon them long before we had our existence, and they will be traced there long after we are gone to our silent homes. Standing as they do, unmoved by the storms of ages, while the finest monuments of art are crushed to the dust, they present to the observer, a page of that great volume, where there is grandeur of causes, sublimity in effects, and harmonious order. It is not for the gratification of that indolence which seeks relief from the burden of existence in the chase of frivolities, that the scholar interests himself in such studies. In following his own inclinations, he adds to the existing stock of knowledge, and wipes the sweat from the brow of toil. The lover of nature finds new sources of instruction and amusement at every step. Other branches of inquiry may render him wiser, but this makes him both wiser and better. Restraining the violence of passion it draws closer the ties which bind him to his fellow men, and promotes individual happiness by increasing the general good.

To those who cherish the desire of acquiring reputation, Mineralogy holds forth numerous allurements. From whatever source that feeling derives its origin, which forces us to revolt at the idea of being lost in the darkness of oblivion, to be as though we had never been, it is an honorable sentiment. To identify our existence with the monument which marks the spot where our remains shall rest, to be read only in inscriptions and to live only in name, shows but a poor conception of the value of fame. To subsist in lasting memorials, to survive in memory of the benefits conferred, is a laudable ambition. Ours is a country, where all is new, where discovery has not yet explored the extensive regions of its territory, and gathered up all that was worthy of notice. Placed as it were on the verge of the wilderness, at that point where cultivation ends, and the forest begins, the fair fields that lay behind us, show the improvement of which those which are yet unsubdued are capable. The adventurer whom fortune has favored with the opportunities and

advantages requisite for such occupations has only to go forward and he will prosper.

That the strong features of natural character, depend upon the outlines of geological structure, is true to a certain extent. The discussion of the influences of temperature, scenery, or climate, upon the mind, is the province of the metaphysical. No one who has felt the warmth of spring succeeding the cold of winter, will deny that there is much efficacy in such means. Though genius may rise superior to the depression of a foggy atmosphere, yet its highest upward aspirations have been where the heavens are fairest, and the face of nature most lovely. In the genial regions of the South, painting and sculpture have arrived nearer to perfection, and poetry which is the representative of the feelings of a people, has breathed in softer numbers than in the ruder districts of the North. In those wild countries its notes have had more boldness and originality, and have given expression to those high toned sentiments and patriotic feelings so congenial to the land of forests, rocks and precipices. It is not unphilosophical to ascribe these differences to the effects of varied circumstances in the geographical situation or the surface of a land. If observation confirm the position, that regions like Switzerland and America, whose mountains lift themselves to vast elevations above the sea, are those places where independence of thought and action exist, we have only to ascertain whether the lofty ridges of a primitive section, rise into abrupt and craggy summits, or whether the surface is diversified by the gentle swellings and undulations of a less marked formation, to determine whether a nation possess the hardy spirit of freedom or are sunk in the degradation of slavery. Without venturing the extravagant length of asserting that Quartz or Feldspar, or any other mineral are essential to human prosperity, or that genius and virtue must be circumscribed by the boundaries of Limestone or Granite, we may safely venture to say that the prominent characteristics of a people may depend upon the structure of the country they inhabit.

A single remark more upon the satisfaction resulting from the study to which we have adverted, and we have done. He who has accustomed himself to minute observations on the various products of the earth, if he does not possess himself of wealth, yet opens numerous stores of amusement. In every rock he recognizes the rugged face of an old acquaintance, in every stone beneath his feet he renews his intimacy with a friend. To select where all is beautiful, to give a decisive preference where all is inviting, is injustice. Renouncing that limited prejudice, which seeks to exalt a favorite, by disparaging every other object, he who contemplates nature will delight to survey all her works. He will find

“—tongues in trees, books in the running brooks,
Sermons in stones, and good in every thing.”

Selfishness is the hydra we should be perpetually combating; for the monster has so much vitality, that new heads spring up as fast as the old ones are cut off.

FACTS AND OBSERVATIONS RELATING TO
AGRICULTURE & DOMESTIC ECONOMY.

FOR THE NEW ENGLAND FARMER.

Extracts from an Address delivered before the Western Society of Middlesex Husbandmen, by Rev. Wilkes Allen, A. M.

"It was the complaint of a learned investigator of the works and ways of nature, and of an experimental farmer before the formation of any agricultural society in America, that though men of business, ingenuity, and observation, might find out things valuable and useful, yet for want of some proper method to communicate them, they would die with the discoverers, and be lost to mankind.*

"By association and a free interchange of thoughts, the discoveries and improvements of one become the common property of many. By example and conversation the mind receives a powerful impulse to action. It shakes off its indolence, and puts forth new efforts to equal a superior, or rival an equal. It seizes upon new tracks of thought, and pursues them to some new and important discovery. By social intercourse, knowledge is diffused, emulation inspired, the attention fixed on new objects, and growing attainments are secured. Associations of men of the same occupation and employment have been vastly beneficial to one another in various ways. But the useful tendency and beneficial influence of associations for specific objects will not, I trust, be disputed in this society-making age."

"The beneficial influence of agricultural societies has been experienced in breaking up long established associations, unfriendly to improvement. Within the memory of many now living, each successive generation walked in the steps of the preceding. The same field was planted in the same manner for a century. Any deviation from ancient usage was deemed disrespectful to the memory of the dead. Prejudice and error were hereditary, till science with her torch led on to new discoveries, and experience elucidated and enforced the truth and importance of her decisions."

"The advantages of agricultural associations are not confined to annual exhibitions and shows and to the collection and distribution of information. "Their purposes terminate not in instructing in new courses of husbandry, but in introducing new principles of action." By calling the works and improvements of the retired and unknown farmer into public notice, you place him in some respects on an equality with men of other professions, who are constantly moving in a public sphere, and acting in view of the multitude of spectators. You at once excite in his breast a strong desire to excel in his art by making him realize, that his art or profession is an object of public attention, and a means of obtaining celebrity. You at once touch the main spring of action, by pointing out a road to fame, honor, and emolument, and placing the obscure agriculturist in the high way to that distinction, which the physician, the lawyer, and the divine, enjoys by excellence in his profession. The ultimate object of agricultural societies is to give new strength to the common spring of action, ambition to excel in the art or profession of a farmer."

"The potatoe was not known in Europe in Queen Elizabeth's day, and her sallads were imported from Flanders."* In this country, nearly a century elapsed before the kind and salubrious properties of the potatoe were known, and its important uses discovered. This great benefactor of mankind was long viewed with a jealous eye, and taken into the stomach with as much caution as the most nauseating medicine of the physician. But whence this change in public feeling, sentiment, and practice? It is unquestionably owing to a few enlightened individuals forming themselves into companies, setting out on enterprises of discovery for the good of mankind. As in the sea, wave impels wave to the shore—so in society, man acts upon man. His example, the benefit resulting from his enterprise, the public honor with which it is crowned, all conspire to excite in those around him a noble emulation. The flame of emulation catches from breast to breast, as the electric flash passes through contiguous bodies, till the whole community feels the impulse first given by a single individual."

"Gentlemen, the association you have formed and are attempting to found on a rock, a fund, which is to give vital animation to you and all around you, is an institution of great importance to the general interest and prosperity of the country, and especially to those within the sphere of its influence. To promote and secure the wide and lasting benefits, which, it is confidently believed, may result from it, every member must feel himself of vital importance, and act as though its whole prosperity depended on his exertions. Never lose sight of the object, which is *improvement in domestic manufactures, and every branch of field husbandry*. Need I remind you of the immense field open for your exertions? Need I remind you, that the walls, which your forefathers built, are fallen down, the orchards they reared up, decayed, and the pastures they cleared, grown over with thorns and briars? Need I echo in your ears a truth, which every where meets the traveller's eye, that there are yet vast tracts of unproductive land, capable of the highest improvement, and wanting nothing but the plough, the hoe, and the hod, to make them just what the possessors would have them to be, fruitful fields, and well cultivated gardens? Diminish the quantity and increase the good quality of your lands, and you will have the means of supporting handsomely two families, where one now scarcely obtains a comfortable living. I am borne out to the full in this assertion by the experiments of many practical farmers.—Particularly by those of Mr. Upton, Superintendent of the alm-house farm in Salem."

"You begin your labors, Gentlemen of this Society, at an age, and under circumstances, which promise all the most sanguine can expect. A new agricultural era has commenced. Men of learning, talents, and influence are enlisted in the cause; and the public attention, released from the labours, cares, and ravages of war, is directed to the interests of agriculture. Your art and profession as husbandmen are rising to their native rank and dignity; and to accelerate their progress you must diffuse useful knowledge, and improve the education of

these destined to agricultural pursuits. Knowledge and virtue adorn and dignify the human character. They add respectability and dignity to bodies politic as well as to individuals."

*It is a remark applied by a late writer, to France, but equally applicable, it is believed, to America, "that agriculture till of late has been considered a degrading employment." The reason why it has been so considered will be found in the want of education, knowledge, and intellectual improvement among that class of people, who exercise this art. Increase the moral and literary attainments of the great body of agriculturists, and you exalt their character and profession. Too long has the error existed, that a classical or academic education is lost upon those, who are designed for agricultural pursuits. Fatal to the usefulness and virtue, to the hopes and prospects of many young men of more than ordinary education, has been the idea, that the labors of the field or the mechanic's shop are beneath *their dignity*; that knowledge raises men above, and disqualifies them for the necessary and more humble, yet useful employments of life. To young men of these feelings and sentiments, we would recommend the careful perusal of the following lines of the poet.

A little learning is a dangerous thing;
Drink deep or taste not the Pierian spring;
There, shallow draughts intoxicate the brain,
But drinking largely sobers us again.

This hint, it is hoped, will be sufficient to induce the more opulent farmers of our country to raise the standard of what is commonly called a good education for farmers' sons, destined to follow the profession of their fathers.

HOW TO DISTINGUISH CATTLE WHICH HAVE A PROPENSITY TO FATTEN.

Mr. Culley, a famous English breeder, has given the following directions relative to this subject. "We undoubtedly first judge by the sight, which being pleased we bring the sense of feeling to its assistance; and if this also approves, we then conclude that the animal suits our purpose, or is answerable to the idea we have formed of it. A nice or good judge of cattle or sheep with a slight touch of the fingers upon the fatting points of the animal, viz. the hips, rump, ribs, flank, breast, twist, shoulder-core, &c. will know immediately whether it will make fat or not, and in which part it will be the fattest. I have often wished to convey in language that idea or sensation we acquire by the touch or feel of our fingers, which enables us to form a judgment when we are handling an animal intended to be fatted—but I have as often found myself unable to fulfil that wish. It is very easy to know where an animal is fattest which is already made fat, because we can evidently feel a substance or quantity of fat upon all those parts which are denominated the fatting points; but the difficulty is to explain how we know or distinguish animals in a lean state, which will make fat, and which will not, or rather which will make fat in such points or parts, and not in others; when a person of judgment (*in practice*) can tell as it were instantaneously: I say *in practice*, because I believe the best judges *out of practice* are not able to judge with precision, at least I am not. We say this beast *touches* nicely upon the ribs, hips, &c. because we find a mellow, pleasant feel on those parts; but we do not say soft; because there are some of the same sort of animals which have a soft loose handle, of which we do not approve, because though soft and loose, they have not the mellow feel above mentioned: for though they both handle loose and soft, yet we know that one will easily become fat, and that the

Butter—Russian mode of Making—A New Discovery.

Sir—Observing in your paper last evening, a communication from Mr. Hugh Hartshorn* to J. S. Skinner, Esq. on the subject of making Butter in Winter, I beg leave to furnish a few particulars on that subject, as practised in Russia, since the year 1816, and which, may perhaps, be of some service to those who may be induced to make the experiment, either in Summer or Winter. Being in that country in the year 1817, I was informed by a Russian Nobleman that the proprietor of an extensive estate (also a Nobleman of high rank) had discovered a new mode of making Butter, and had received letters patent from the Emperor as a reward for the discovery, and which he stated as being at that time in full and successful operation. The process consisted in boiling (or rather that species of boiling called simmering) the milk for the space of fifteen minutes in its sweet state—observing at the same time not to use sufficient heat to burn the milk; it is then churned in the usual manner. He also stated that no difficulty ever occurred in procuring Butter immediately, and of a quality far superior to that made from milk which had undergone vinous fermentation; and that, in addition to its superior flavour, it would preserve its qualities much longer than that made in the ordinary mode; that the additional advantages were, that the milk, being left sweet, is possessed of almost the same value for ordinary purposes, and by some was considered more healthy, as they supposed the boiling or scalding to destroy whatever animalculæ it may have contained.

If the above process should upon experiment prove of sufficient importance, so as to bring it into general use, particularly in the winter, it would perhaps be to the advantage of those who may practice it to have their milk scalded in vessels calculated to stand in the kettle or boiler, by which mode the danger of burning the milk would be avoided, for it is ascertained that milk only burns on the edges of its surface, or where it comes in contact with the sides of the vessel in which it is heated, which can never happen in double kettles, or where one is placed within the other.

TO CURE NEAT-CATTLE OF THE MANGE.

Pennsylvania, April 12th, 1822.

DEAR SIR,

When your Cattle have the mange, cause them to be well washed with soap—at night, give half an ounce of nitre; repeat it the next morning. If the weather be good, rub well on all the parts affected, some ointment, prepared by the subjoined recipe—let them be kept under cover for two days and nights, then turn them into the field where they can run, produce sweat and rub themselves; if necessary, repeat this treatment. This disease sometimes attacks the fat, and the thin. I have never failed in attempting a cure, and within five weeks. Pinch the tail throughout, if any soft place be found, slit it with a sharp knife so far as the softness extends. I know from an accurate observation.

during four years, and minute investigation of the practices of the best graziers, (with whom I have much to do) that such state of the tail is proof of tendency to "hollow horn." I mean that the "tail rot," as it is called by Downing, the English Cow Leech, is a symptomatic disease indicative of some affection of the spine, which generally produces a more fatal malady, accompanied by hollowness of the horns.—A small quantity of white mucus, or serum like stuff, exudes generally from the incision.

In New England, they all cut off the tails.—I cut off the long hair, at the ends, but never remove any portion of the bone, although I do not hesitate at pushing a sharp knife through the soft parts of half a dozen calves or cows tails in a morning. I have seen an animal on her side, which, within half an hour, was led to rise and after eat, merely by cutting off three inches of the tail. Some of the best Surgeons to whom I have spoken, think that my notions are perfectly consistent with the received opinion of the connection between the spine and tail of a quadruped. The remarks of some of the old farmers of this county, excited my ridicule on this point, at first. They go so far as to assert, that the tail is injured by treading on its end when the animal makes an effort so rise—the most skilful farmers, and the most celebrated in this neighborhood, among us fellows who do not faint at smells, cut off the hair for the reason I have given.

I would be glad to welcome Mr. C***** here. The finest grazing land in the Atlantic States, I think is the alluvion on the West Bank of the River Delaware. And the best Grazing Farms could be purchased on its margin, at very moderate prices.

I have a letter from Massachusetts, saying that Cælebs had 52 cows at \$10 each.

Ointment for the Mange.—11egs lard, 2 lbs.; spirit of turpentine, half a pint; oil of vitriol, 2 ounces, to be well mixed; after add brimstone in fine powder, half a pint.

My cattle all take from one to two ounces of salt daily in their food—once in a fortnight, half an ounce of salt petre.

AMERICAN CUTLERY.

We have now before us three pocket or pen knives, made at Pittsburg, and commonly sold in the shops of that city and its neighbourhood—a four bladed knife at 150 cents; a two-bladed knife at 62 1-2 cents.—These are the retail prices, and as low as knives of like quality can be fairly imported and sold at. This is what we did not expect. We have seen knives of Pittsburg manufacture, that cost 5 dollars, which in every apparent quality, rivalled the best products of Sheffield, at a similar amount of price: and excellent razors are also made at the same place. These things are furnished by regular manufacturers. We also observe extensive establishments at New-York, wherein tailors' shears, scissors, penknives and razors, are made and warranted to be of the best quality. One of the great advantages of home manufactures, is the direct responsibility of the manufacturer to the public, which is just as wholesome in itself, in a maker of razors, as in a maker of treaties with foreign nations, or in contracts that involve millions of the people's money.

Am. Ingham Chronicle

other will not; and in this lies the difficulty of the explanation; we clearly find a particular kindness or pleasantness in the feel of the one much superior to the other, by which we learn that the one will make fat, and the other not so fat; and in this a person of judgment, and in practice, is very seldom mistaken. I shall only make one more remark, which is, that though one animal will make remarkably fat, and the other will scarcely improve at all, with the same keeping; yet between these extremes are numberless gradations, which the complete judge can distinguish with wonderful precision."

Sir John Sinclair observes, that "Handling cannot easily be defined, and can only be learnt by experience. The skin and flesh of cattle, when handled, should feel soft to the touch, somewhat resembling that of a mole, but with a little more resistance to the finger. A soft and mellow skin must be more pliable, and more easily stretched out to recover any extraordinary quantity of fat and muscle, than a thick and tough one. The rigid-skinned animal, must, therefore, always be most difficult to fatten. In a good sheep, the skin is not only soft and mellow, but in some degree elastic. Neither cattle nor sheep can be reckoned good, whatever their shapes may be, unless they are first rate handlers."

DIRECTIONS FOR RECOVERING DROWNED PERSONS.

The following directions have been published by the Dublin Humane Society:—

"What thou doest, do quickly."

1. Convey the body carefully, with the head a little raised to the nearest convenient house.
2. Strip and dry the body; clean the mouth and nostrils.
3. An adult lay the body on a bed or blanket near the fire or in a warm chamber; if in the summer, expose it to the sun.
4. A child; place it between two persons in a warm bed.
5. Rub the body gently with flannel, sprinkled with spirits.
6. Restore breathing by introducing the pipe of a bellows (where the apparatus cannot be immediately procured) into one nostril, keeping the other and the mouth closed, gently inflate the lungs, alternately compress the breast, and then let the mouth and nostrils free.
7. Apply warm bricks to the soles of the feet, and warm spirits to the palms of the hands, and the pit of the stomach.
8. Persist in these means for three hours at least, or until life be restored.

Cautions.—1. Never to be held up by the heels.

2. Not to be rolled on casks, or other rough usages.
3. Not to allow into the room more than six persons.
4. Not to rub the body with salt.

General Observations.—On signs of returning life, and if swallowing be returned, a small quantity (often repeated) of warm wine and water, or diluted spirits, should be given; the patient put into a warm bed, and if disposed put to sleep.

Electricity and bleeding are never to be employed, unless by the direction of a medical gentleman.

MR. GARNETT'S ADDRESS,

Delivered before the Fredericksburgh, (Va.) Agricultural Society at their late meeting.

FELLOW CITIZENS :

It affords me a degree of gratification which I cannot easily express, to behold so conclusive a proof, as this assemblage presents, that we have at last become sensible of the great benefits which may result to our agriculture from similar meetings and exhibitions, to the one now before us. And I beg leave to avail myself of the present occasion, to offer my cordial congratulations to all my agricultural brethren who may now be with us, on this auspicious commencement of our long meditated Agricultural Shows. It is true, that we have not, nor could we have, for the first time, an exhibition, to be compared with the many highly imposing, and praiseworthy spectacles of a similar character, which have, for some years past, distinguished our sister States, to the North. But we behold enough to afford us great encouragement, and a fair promise of much better things hereafter.

It would be passing strange indeed, at a time when skill, zeal, and industry are pushing on all the ether arts of civilized life to their highest state of attainable perfection, if that art, which fills the purse and sustains the sword of the nation; that art, by which, under God, we all live, and move, and have our being; which supplies not only most of the necessities, but also of the comforts and luxuries of our existence, should be the only one neglected and despised among us. Yet this has been the fate of our agriculture, until within a few years past. And there are still some among us, I fear, who, in their insatiable reliance upon the innate energies (as it would appear) of their art, or on some other yet more incomprehensible dependence, rest, with folded arms, and drawn as it were within their own shell, without ever spending a thought, moving a finger, or bestowing a cent towards the improvement of this first and best of all occupations. Can they imagine it is all-sufficient to take care of itself, single-handed, and without any concert or co-operation among those who pursue it? Is it so unlike all other avocations and professions in life, that the insulated powers of each individual, engaged in it, will suffice of themselves to bring it to perfection? No, my friends, there cannot be a more absurd, nor pernicious notion, than the belief, that each man, for himself, can study and practice any, or all the branches of husbandry, with equal advantage, in seclusion from his agricultural brethren, as if he frequently mixed with them, and sought to realize all the benefits of their experience, as well as of his own. If such belief be not sheer madness, it is, at least, the pitiable folly of those who are far too wise in their own conceit, either to receive, or impart knowledge. As well might we expect, that the plants which are reared for human sustenance, would yield their fruit without human labor; or that the aggregate products of human industry, exercised in all the infinitely diversified pursuits of life, would be found spontaneous in their present abundance, as that the theory and practice of agriculture can be brought to perfection, or made even to approximate, in any very profitable degree, towards it, unless her sons can be prevailed upon to act more as a body, moving in harmonious concert—at least, in regard to their great leading interests. In other words, they should seek opportunities of

frequently meeting together; of conferring, consulting, and combining for the general good; of interchanging the results of individual experience and observation; of encouraging by joint, but voluntary contributions, such exhibitions as we are now endeavoring to establish, with a view to elicit all that is known among us, in regard to the improvement of stock, of agricultural implements, of the various processes by which the soil itself can be best cultivated, and most effectually fertilized—and, in short, of doing every thing in their power, to elevate, to honour, and to perfect the profession to which they are devoted. With such views and objects, always present to our minds, were we zealously to pursue such a plan, for a few years, and exert, for its promotion, all the agricultural talent and information among us; instead of the afflicting prospect of deserted habitations, falling into ruins—of fields, once under culture, but now barren, desolate, and rarely trodden by the foot of either man or beast; instead of frequently having to undergo the pangs of separation from our dearest friends and connexions, compelled to seek, in distant regions, that support which our exhausted soil can no longer yield, we should behold the heart-cheering, delightful spectacle of a moral, industrious, well informed, and happy population, gradually, but continually increasing, in a ratio proportioned to the augmented fertility of our lands, and the consequent expansion and multiplication of our agricultural resources. We should no longer witness the rapid depopulation of several of the good old United States from the operation of that ever restless, erratic spirit, the general tendency of which is, to convert civilized man into a kind of wandering Arab, a stranger to all the endearing associations, connected with the words "native home;" always in search of new pastures for his herds, new forests to subdue, and new fields to wear out, as fast as the process of continually exhausting culture can destroy them. For my own part, I have always been strongly inclined to doubt our moral right to pursue such a course; for the same general law, acknowledged by all rational men, which forbids us to abuse any of the gifts of our beneficent Creator, and which we willingly obey, in taking special good care of the constitution of our bodies, ought to lead us, I think, also to take care of the constitution of our soil, as an essential means of attaining the first object. A contrary course of conduct, if pursued by all the nations of the earth, would evidently have rendered the whole habitable globe itself, in the course of a few centuries, inadequate to the support of its inhabitants. To improve our agriculture, therefore, is a moral duty, as well as a rational, agreeable and profitable occupation. In a political point of view, there is nothing in this world, the contemplation of which, can give higher animation to the hopes of the true Statesman, and swell the bosom of the genuine patriot with more pleasing anticipations of his country's prosperity and happiness, than the prospect of realizing such a state of society, as an agricultural people may form and maintain, if they will only avail themselves of all the means which are naturally connected with, and grow out of their pursuits, for the promotion of knowledge and virtue; for the security and beneficent use of property; and for the permanent enjoyment of the highest degree of earthly felicity, which social man is capable

of attaining.—This, my friends, is no romantic vision; no picture, the coloring of which is borrowed from an imagination, too sanguine, in regard to what *may* be done, provided only proper means are used, and assiduously applied. It would occupy more of our time than we can now spare, to attempt even a brief enumeration of these means. Let it suffice for the present, that I earnestly entreat you to turn your attention of tender to the objects at which I have merely hinted. There is nothing can afford us ampler scope for improving reflection, nor any thing in which our temporal interests are more deeply concerned.

Although the foregoing speculations may not appear to have any immediate connexion with the purposes of our present meeting, they have been suggested by it; and as long as I have the honor to be connected with this society, I shall ever deem it my duty, to press similar topics upon the attention of its members, on every suitable occasion. If they serve no other end, they may aid in illustrating the relative importance of the agricultural portion of our people, as a component, and most material part of our great body politic; in awakening sufficient vigilance, to guard against encroachment on their rights; and in rendering them more sensitive of the too frequent attempts to legislate them into mere "hewers of wood and drawers of water." Not that I mean to charge the authors of these acts with *designing* such an effect; but if it be really produced, the purity of their motives would be but a poor alleviation of the evil.

Let me now solicit your attention, for a few minutes, to the particular objects of our present meeting; and to an endeavor, briefly to point out some of the many advantages resulting from such exhibitions; as well as to suggest a few hints, in relation to the feelings and views of those who attend them—either as mere spectators, contributors, or competitors for distinction.

We all well know the slow progress made by agricultural improvements, and the time which always elapses, before they get into general use. Our scepticism, in this respect, exceeds that even of St. Thomas himself; for we believe nothing that we hear—and require not only to see, and to feel, before we give any credit to what we are told; but rarely then, act immediately upon our belief. The History of the Carey or Dagon Plough among us, furnishes a remarkable an instance of this fact, as any that I have ever known. The two first ever brought to this town, remained in the stable yard of the Indian Queen Tavern nearly a year, before any one would even *try* them. During all this time, they lay the objects of doubt and cunning suspicion, to all the knowing ones, each fearing to meddle with them, lest he should render himself a mark of ridicule to the rest, for putting any faith in so ill-looking a tool. And there probably they would have continued for years, if an enterprising Yankee, then a resident here, had not boldly resolved, at every risk, to achieve the perilous adventure of making the first trial. Even after he had demonstrated the merit of this plough, I dare say it was nearly ten years, before it was generally used in all the contiguous parts of the country. Nearly a similar fate has attended those superior ploughs, which have been slowly superseding the Carey. One principal reason, perhaps, of this may be, that after our cobbling Smiths once get into a

of generally making a new agricultural implement, according to their fashion, which frequently resembles almost any thing better than an article designed to be imitated; a common opinion prevails, that this implement costs us little or nothing, because we pay for it after months, and often years of delay, in some kind of agricultural product—or, because, as it counts an item in that unlucky thing called a blacksmith's account, it is never paid for at all. There is so wide a difference between this method of obtaining our agricultural implements, and buying what is emphatically called "actual cash" for them; that the Solomons of our tribe, who are never surprised into the juvenile indiscretion of being the first to try a new thing—especially if it comes from a distance, and "costs money?" can scarcely yet forego the prophetic pleasure of shaking their wise heads at, and conning to ruin the man who dares to violate this cardinal maxim of their rural economy. Nothing is better calculated to banish these ridiculous prejudices; and nothing more facilitates the general adoption of agricultural implements, of every kind, than the frequent recurrence of spectacles of a similar character to the present. For, on such occasions, we become eye-witnesses of most of those inventions, which mechanical skill and ingenuity have devised for our use: and of which, we either might not hear for years; or if hearing, might discredit, provided we confined ourselves, as many do, to our own farms, nearly secluded from all intercourse with our fellow citizens, but such as live next door to us. That mind has never yet been formed, believe, which could bear such seclusion, without being contracted, and materially impaired by it. Another advantage, and by no means the smallest, evidently resulting from such associations, is, that we learn to appreciate more fully the capabilities of our art, when ocular proof is exhibited to us of what can be effected by those who follow it assiduously, under the influence of those powerful, because *voluntary* encouragements, held out to them by agricultural societies. Hence, we are naturally led to estimate more highly the power, resources, and honorable character of agricultural pursuits, in comparison with any other, instead of undervaluing them, as far too many of us appear to do. Men, in fact, must respect themselves and their profession, to obtain the respect of others. And unless our agricultural people evince their regard for their own occupation, by always asserting the rank to which they have a just claim, on the great scale of national interest, they may count with certainty, upon being degraded, not only in public estimation, but likewise in their own.

As to the feelings and views of those who attend such exhibitions as the present, in the character either of spectators, contributors, or competitors for premiums, I will now offer a few remarks. Of the first, I shall only say, that I take it for granted, they have come well disposed to be pleased with the humble effort made to interest them; and to engage their good wishes, for the success and continuance of our undertaking. In regard to the second, although confidently trust, that we all think much alike on the subject of our institution, yet I cannot forbear to suggest, that, if they notice any thing which falls short of their expectations, they must not too soon be discouraged; nor suffer a

small failure at first, to deter them from another effort to get up a Show and Fair, which shall be worthy of the extensive and fertile country, over which our society has already diffused itself. In one year more, we may hope for such an accession of members, (the annual contribution being only two dollars,) as will considerably augment the premium fund, which we shall zealously appropriate, in the best manner our judgments can devise, for promoting our good cause; and *if we fail*, (a misfortune I will not anticipate,) it shall not be the fault of the Agricultural Society of Fredericksburg.

And now, before I conclude, I must make free to suggest a few hints, for the consideration of those who mean to compete for the premiums which we have already offered.

As our society in making this offer, have been prompted solely by their wishes to promote the general good, they have studiously endeavored, in selecting their committee of premiums, to secure such awards as will be equally disinterested and exempt from all local or partial considerations. Should any individual competitor, therefore, be inclined to question the correctness of their decision in this particular case, I must be permitted to express my hope, that he will deem it better, silently to acquiesce in a determination which, although it *should be* erroneous, *cannot* proceed from any but correct motives; rather than impair the utility and general good effect of agricultural premiums publicly awarded, by arraigning either the judgment, or the equity of men, who must necessarily decide right in many more instances than they determine wrong. We cannot expect those who fail to obtain rewards to be equally pleased with those who gain them; but we *may & do* calculate on the competitors for our premiums being true and genuine friends to the cause of agriculture. And *if they are*, we can rely fully on those who may be unsuccessful, making all due allowances for their respective failures; so far at least as to acquit *our* committee of any design to thwart their particular efforts to gain the prizes at which they have aimed. I feel the more solicitous on this subject from my anxious wish that in this our first attempt of the kind, no circumstance should occur, either to produce disagreement among ourselves; or to throw the slightest obstacle in the way of our future exhibitions. Not that I fear either the competency or inclination of our committee to decide correctly: But the same thing *may possibly* happen *here*, which I see by the public Journals has taken place in one of our sister states; and I would willingly guard against it by a timely caution. The case alluded to, is one of an individual, *evidently interested*, coming forward to arraign either the judgment, or the justice, or both together, of certain judges, as *evidently disinterested*, who were selected by one of our sister societies to form a committee of premiums. This being a common cause to all agricultural societies, I must take the liberty to offer one or two general remarks prompted by the occasion. Any such instance of palpable selfishness, so far from engaging public sympathy, cannot fail to excite unqualified disapprobation. The public, whose sense of justice, will always lead them to right decisions in the end, will never take part with an individual who complains of what *he only* conceives to be an injury, and that to *himself alone*, in opposition to

the decision of numerous and obviously *impartial arbiters*, who are so circumstanced, as to have *no possible interest*, either direct, remote, or contingent in deciding against him. At the worst, such a decision can only be an insulated and single mistake, unaccompanied by any of those general consequences, which threaten injury, either to the community at large, or to any portion thereof, considered as a separate class.

I must now, my friends, bid you farewell. We have all met, as I sincerely trust, with feelings such as should ever govern men engaged in a common cause, and bound together by the ties of a common interest. Let us all part in the same spirit, to meet again, twelve months hence, with increased hopes and wishes for the prosperity of our Agriculture, as the true basis, and best security for the permanent welfare and happiness of our beloved country.

TO THE EDITOR OF THE NEW ENGLAND FARMER.

I was pleased to see in thy paper of Nov. 16th, a demonstration that my rule for gauging is true. The rules of the author of that piece are ingenious and correct, yet far more tedious than the mode by which I discovered my rule, which I now consider myself in duty bound to explain and render intelligible to any person, master of the common rules of arithmetic.

I must first premise that it is demonstrated by Euclid that the contents of all circles are in proportion to the squares of their diameters.

Second, that any *division* may be performed by *multiplication*, and frequently requires fewer figures. The performing of division by multiplication is founded on the neutral properties of an *unit* or *one*, which none of the authors on arithmetic appear to have explained, or perhaps fully to have understood;—for to multiply one by one, or to divide one by one, the product and quotient will be the same; therefore as one can neither be increased nor diminished by multiplying or dividing by itself, it is a stationary number in either rule. For instance, suppose we wish to divide 8 by 2, by multiplication, divide 1 by 2 and the quotient will be .5—then multiply 8 by .5 and the product will be 4, and the same rule will hold equally good in any larger numbers. Then as it is proved by Euclid that the contents of all circles are in proportion to the squares of their diameters; say by the plain Rule of Three, as the content of any circle is to the square of its diameter, so is 231, the cubic inches in a gallon, to 294, the number to divide by to find the gallons, if we take the square of the diameter in place of the content of the circle—but as 294 is a tedious number to divide by, perhaps the division would be more readily performed by multiplication; therefore divide an unit or one by 294, and you have .0034 for a quotient to multiply by to find the true content.

As the ingenious gentleman "*Hhd. alias 4 Bbbs.*" has demonstrated the same thing in a very different and more tedious manner, it appears that we are both correct, and I would wish for a further correspondence with him on various Theorems, not doubting but many useful rules may be discovered, more short, plain and easy than what they have been laid down by European Authors.

SAMUEL PRESTON.

Stockport, Pa. Nov. 29, 1822

From the New-York Statesman.

TO WOOLLEN MANUFACTURERS.

I beg leave to inform you that a bed of excellent Fullers' Earth has been discovered on the margin of the North River, in the State of New York. As this article has ever been considered a grand desideratum in the Woollen Manufacture, I congratulate you on the discovery, and more particularly that it is owned by an individual who possesses so much liberality as to offer it for sale in this city,* at the same price it is sold at in the manufacturing districts in England—thus placing you, so far as this article is concerned, on a par with European manufacturers.

As it is presumed you are mostly unacquainted with its use and value, I have, for your information, added a statement of the mode of applying it, and the advantages to be derived therefrom.

You must be aware that Fullers' Earth is the only material with which coloured cloth ought to be cleansed, as well black as blue; and that before cloth is coloured in the piece, it is absolutely necessary to use this article to prepare it to receive the dye. You may not, however, be equally aware that the superiority of the colors imported from Europe, are in a great degree attributable to their using this earth, after the manner hereinafter described.

Fullers' Earth, when dry, if good, should be smooth and slippery like soap: It should not perfectly dissolve in water, but when immersed in that fluid in a dry state, it falls so as to assume the appearance of suds, and on rubbing the hands with it in this state, it ought to be free from grit and perfectly smooth. Its use on cloth, is first to clean all the soap and grease out after braying and before fulling, and to cleanse the color and soap out after fulling. In coloring of cloth it is ever used to prepare it for the dye, and to cleanse the color after dyeing. Earth is not only the best agent with which to perform these operations, but what is equally important, it is the cheapest of any, as it will be sold at one dollar per one hundred pounds.

On cleansing of cloth previous to and after dyeing.

Many of the minor operations in a factory, which those who are not well versed in the business are apt to neglect as of little or no consequence, have an important bearing on the well-being of the whole. Such are the operations I am now about to describe; and I am sorry to have to observe that they are too generally neglected in this country. I must remark (and it cannot be too forcibly impressed) that to clean cloth well from grease and other extraneous matter, previous to dyeing, is a necessary preliminary to the production of good colors, and to cleanse them well afterwards, is equally necessary to the maintenance of the manufacturer's reputation.

Blue, black, and other dark colors, are steamed before they are carried to the fulling mill; they are then taken to the stocks and washed under the hammers; until the water runs clear from them, when they are taken out and hung upon long wooden pegs (placed in the walls of the building) till the following day; they are

then taken down, spread open, and wet Fuller's Earth thrown all over the face; the lists are now thrown together, and they are carefully placed in the stocks, which are plugged up, and the hammers let down, and permitted to play on the cloth, without water, for half an hour or forty minutes; the cloth is then handed out, the lists pulled square, and the earth spread even on the cloth, and more Earth added if necessary; the cloth is then put again into the stocks, and the hammers suffered to play upon it one or two hours, after which a small quantity of water is let run into the stocks; not more than would pass through a large wheaten straw, for one hour, in order that the Earth may be diluted slowly and by degrees. After that, the cloth is once more handed out, the lists pulled square, then put again into the stocks, and the plug pulled out, when a sufficient quantity of water is introduced to make it perfectly clear. During the last operation, it is to be from time to time handed out, in order to prevent its taking a wrong position in the stocks, and being torn.

The water that comes out of the stocks shows whether the cloth is clean; for that which runs out ought to be equally as clear as that which runs in.—If on trying the cloth, you perceive it still soils, it must be worked with Earth a second time. River or clear rain water is the best to mix with the Earth, and spring water for washing it out.

To prepare cloth for dyeing, it must be worked with Earth as before directed, only when it has gone the first half hour in the Earth, a small stream of water is let run in for half an hour, and then a full stream, until it is quite clean.—The handings out, as before directed, must be observed. Many people color their blacks after fulling, without scouring with Earth; but the colors will not be so good, nor will they clean so well afterwards, because there will always remain a portion of the soap in the cloth, which washing with mere water will not detach from it, and when this comes into the black liquor, or any other dye, the soap will be decomposed; the soda will be combined with the acids, and the grease being liberated, will produce an effect equal to the coloring of greasy cloth.

On cleansing of cloth from its grease in the flannel.

In general, urinous liquor and water are sufficient to clean a cloth from its grease in the flannel after it is woven; but when the wool has not been properly scoured from its yolk, or filth, or when the cloth has been manufactured, a great while, it is necessary to add to the urine a solution of Fuller's Earth, and to do it sometimes two, three, and even four times over, notwithstanding which it is almost ever necessary to work such cloth twice more with Earth prior to fulling; but this is done only after it has been buried.

It is important that cloth should be thoroughly free from grease before it be fulled; for soap which softens grease, but does not dissolve it, forms with it a clammy substance which adheres very strongly to the cloth, and is scarcely ever to be removed by any subsequent operation.

When cloth has been fulled, it has to be washed clean from the soap, and this apparently simple operation cannot be effectually done without Fullers' Earth. Those who have never scoured wool-dyed cloth, after fulling, as the final operation, can have no idea how much the

beauty and intensity of the colors is thereby improved.

Being aware of the disadvantages the woollen manufacturers were laboring under for want of good Fullers' Earth, and suspecting there must be plenty in the country, I last spring handed paper to the editors of the Statesman, requesting samples might be sent to their office to be inspected by a person who was a judge of the article. Numerous samples were sent, and among them I consider that which is now offered for sale, as the best. After trying it on a small scale, I had a box of it sent to an experienced English fuller to try it on cloth, and he pronounced it to be of a superior quality.

The next best sample, and in fact the only other one that was Fullers' Earth, was sent by gentleman from Virginia. This was of excellent quality; but between every layer there was deposited some coarse sand, that would have to be separated by solution, before the Earth could be used. I am informed there is an inexhaustible quantity in the beds from whence the sample was taken.

I mention this fact, to prove that there never will be a deficiency of the article, and to inform manufacturers that should the supply from thence ever fail, I shall be ready to give them instruction (if they need it,) how to separate the grit at a very easy expense.

Editors of papers who are desirous of promoting the manufacturing interest, are requested to give this an insertion.

W. P.

New-York, Nov. 20.

FOR THE NEW ENGLAND FARMER.

MA. EDITOR,

I saw with no small degree of surprise and regret, the Communication under the signature of "A Member of the Berkshire Agricultural Society," in your paper of the last week.

Your correspondent had not a correct knowledge of the facts, or his good sense would, I trust, have placed a more favorable construction upon the feelings and principles which animated the associated agriculturists at the Worcester Cattle Show; at least I might have relied upon his justice and candor to have spared me this intrusion upon your readers. But my apology for repeating, what must be considered as having too little interest, or novelty, is the duty I owe to the Massachusetts Society for the promotion of Agriculture, whose organ I became and what is due to my own discretion; but more especially to the Berkshire Agricultural Society whose merit and exertions I highly estimate and upon whose good opinion I set too high a value, to submit to its silent forfeiture. I am charged in effect—first, with arraying myself as the organ of the Society in the garb of proffered compliment; and secondly, in having forgotten the honorable distinction to which the Berkshire Society was entitled. I should blush to think I did either, and appeal to the following facts for support.

As passing to the busy scene, it was requested of me by my associates of the committee, that if the Worcester Society should honor the Massachusetts Society in a toast, that I should respond thereto. Such notice was taken, in a manner highly hospitable, courteous and polite, in the following toast:

"The Massachusetts Agricultural Society—The soul which animated 'the Heart,' and which is infusing life into the extremities of the Commonwealth."

* The bed from which the earth is obtained, is owned by Mr. Chrystie, of Fishkill-Landing, and is sold by a person of the same name, who keeps an earthen-ware store in Maiden-Lane.

However gratifying it was, to be supposed as to deserve, and however honorary and distinguishing the compliment from such a source, as the Massachusetts Society had never made any claim for the ascription of so high an use; but on the contrary, at their first Address at Brighton, by a distinguished officer, and all their proceedings, had most gratefully acknowledged the successful efforts and co-operation of the County Societies, it was deemed both just and proper to make such observation as might indicate a due sense of the compliment contained in the toast, as well as of the polite manner in which it was introduced, and point to the County Societies as the sources in which this "animation," so gratifying to those who delight in the prosperity of agriculture, is essentially derived. The toast, therefore, when in response, was with this view, preceded by the following remarks.

The Worcester Agricultural Society was constituted upon the respectable assemblage of individuals who were with such zeal engaged in the promotion of its objects.

Upon the very gratifying display which to the honor of the Society had been offered for exhibition.

And upon the happy results which such a state of things gave the community a well founded right to expect, in the advancement of the Agricultural interests of the state.

In reply to the notice which they had seen fit to take of the Agricultural Society of Massachusetts, it would be recollected that whatever success had arisen by their exertion, the praise belonged to the agriculturists of every part of the Commonwealth.

But now that the several county societies are so zealous and so distinguished in their several spheres of exertion, it was to their co-operation that the Massachusetts Society and the country at large might well look with confidence. I have a right to expect the most auspicious results.

The expression of a wish for their future prosperity, introduced the following toast:

The Worcester Agricultural Society—May their success be commensurate with their zeal, intelligence and patriotism."

I hope, in this explanation, to have satisfied a member of the Berkshire Society" that I do not forget, but had fully in mind the "honorable distinction to which the Berkshire association was entitled." The praise so ardently bestowed by Mr. Lowell, in his Address, and so emphatically quoted by your correspondent upon the vigor and intelligence of the Berkshire Society as having been productive of great emulation of improvements in Agriculture," most indisputably evinces the respect entertained by the Massachusetts Society for that of Berkshire. The recommendation of "prudence, caution, delicacy, and circumspection," is of high authority and should have great weight.*

A generous emulation must produce the best effects; but a jealous rivalry will place all at hazard. To produce the former, will be the plan of the Massachusetts Agricultural Society; and, as your correspondent declares, "it is not an intention to provoke any collision or inauspicious rivalries among citizens and societies devoted to the same great and useful pursuits."

President Adams' Letter,

It is hoped that this explanation may give him satisfaction, and his zealous efforts come in aid of what constitutes the interest of each and every society, the common welfare and happiness.

I am respectfully, Yours, &c.

JOHN WELLES.

THE FARMER.

BOSTON:—SATURDAY, DEC. 21, 1822.

CONGRESSIONAL.

After the standing committees were appointed according to custom, the long agitated subject of the claim of Baumarchais was referred to a select committee of five.—The Rev. Mr. Brackenridge, of Kentucky, was chosen Chaplain of the House after five ballots.—A Message was received from the President relative to the outrages and depredations of the Pirates in the West Indies, and the Gulf of Mexico, exemplified by the death of a very meritorious officer, recommending the employment of such public vessels as are capable of pursuing them into the shallow waters to which they retire.—Another Message was received from the President, on the subject of the Christian Indians in Ohio, and the lands granted to them; and a report on the public buildings was communicated and committed.—A bill respecting the disbursement of public moneys reported the last session was called up, debated upon, and ordered to be reprinted.—A number of bills were introduced and some progress made with them, among which were a bill granting relief to certain citizens in Michigan, who had expended property in relieving captives taken by the Indians in 1813; a bill to provide for the national defence by improving the militia of the United States; and a bill for allowing the widowed mother of Lieut. W. H. Allen, a half pay pension for five years.—A plan for the peace establishment of the Navy was communicated by the President.—A resolution was adopted requesting information from the President respecting advances of money to public agents.—A resolution was passed requesting information from the President relative to the Porto Rico expedition.—On the 13th the bill for the suppression of piracy was read a third time and PASSED without a division, and sent to the Senate for concurrence. This bill authorizes the President to purchase or construct a sufficient number of vessels in addition to those now employed, of such description as he may deem necessary, and to fit them for the services of repressing piracy, &c. and the sum of \$160,000 was appropriated for that purpose.

FARMER SUMMARY OF NEWS.

On Monday last, the trial of Mr. Joseph T. Buckingham, indicted for publishing an alleged libel in the Galaxy, on the Rev. John N. Maffitt, commenced before the Municipal Court. Counsel for the Defendant, Mr. Hooper of this city, and Mr. Hallet of Providence; and the County Attorney, Jas. T. Austin, Esq. for the prosecution. The learned Judge decided that in all cases of indictment for printing a libel, our constitutions secured to the defendant a right to give the truth of the allegations in evidence, to exonerate him from the charge, and that although the County Attorney had granted that permission, he could not claim it by virtue of such grant, as it was due to him by the laws of the land. The examination of witnesses occupied the whole day; in the evening the counsel on both sides were heard, and the Court adjourned. Tuesday morning, Judge Quincy gave the cause to the jury in an eloquent and impressive charge. He divided the charges in the alleged libel into five, to wit: 1. Accusing Mr. Maffitt of falsehood—2. Of infidelity—3. Of betraying confidence—4. Of ridiculing persons who came to the altar—5. Of light, loose and lascivious behavior, and stated the evidence on these points, and directed the jury, if they were satisfied that the truth of these charges was established, and that the publication was made for "a good motive and justifiable end," the defendant must be acquitted; otherwise he must be found guilty. The jury went out at 11 o'clock, and after being absent five hours without agreeing, came in, and inquired of the Judge, whether if in their opinion some of the allegations were proved by defendant, and some were not, they should acquit, or convict the defendant?

The Judge repeated to them a part of his charge to this effect: That if the allegations proved were in their opinion of such a nature, and of such high importance as to authorize the defendant to attack the character of the person with a view to benefit the public by exposing him, then defendant ought to be acquitted. The jury retired again, and in a few moments returned a verdict *Not Guilty*. A full length report of this trial will, we understand, be published in a few days, by Mr. Buckingham, in a pamphlet form.

The last advices from Spain represent the constitutional system as advancing with a fair prospect of securing the happiness and independence of the nation.

Morales, the Spanish General, has published a proclamation condemning to the gallows, or some worse punishment, all strangers found in any way aiding the patriot cause, even as merchants residing in the country. This has been animadverted on with much acrimony by the Governor of Curacao.

A House of Industry has lately been constructed in South Boston, is nearly completed, and is a spacious commodious and elegant structure. It cost about forty thousand dollars.

A fire took place at Cincinnati, (Ohio) on the 26th ult. which destroyed a range of old buildings, heretofore well known as Dickey's tavern.

A bill has been introduced before the legislature of Georgia, "to establish and endow a public seat of learning for the education of females."

A young girl was instantly killed in Philadelphia last week by a stone carelessly thrown by a boy in the street.

Last week, at the S. J. Court, Nathan Severance, of Charlestown, was found guilty on three indictments of passing counterfeit money in Marblehead, and sentenced to four years hard labor in the state prison; his brother Joel, connected with him, and considered the principal, had before been sentenced for life. John How, for stealing a horse and chaise at Gloucester, was sentenced for 18 months.—*Salem Gazette*.

Distressing accident.—On Saturday last (says a Baltimore paper) a young lady, while standing by the fire place unfortunately approached so near the fire that it communicated to her dress. There being no one in the room with her but small children, her attempt to gain assistance by leaving it, served to increase the flames—and before the fire could be extinguished she was burnt so severely that her survival is in consequence rendered very uncertain. The distressing effects of this accident shows that females cannot be too cautious in guarding against it.

An Institution for the Deaf and Dumb has recently been established in Pennsylvania.

A duel was fought on the 30th Nov. between Wm. Cumming, of Georgia, and a Mr. McDuffie, of S. Carolina, in which the latter had his arm broken.

Hay, in large quantities, has been transported from Pittsburgh to New Orleans, where it affords a handsome profit.

New Inflammable Gas.—A short time since a person in this city received, from a gentleman at Springfield, half a barrel of pickles. They came to hand in the evening, and being desirous of looking at them, he took out the bung, when, to his consternation, the moment the air from the cask came into contact with the blaze of a lamp, that was held, it took fire, and continued to burn till the bung was replaced.—*Palladium*.

A New York paper says a live Hog is now on board a sloop at a wharf in that city, which weighs 1465 lbs.

The fever at New Orleans has nearly subsided, and the citizens are daily returning.

James J. Wilson, Esq. of Trenton, (N. J.) Editor of the True American, and member of the legislature of that state, on the 9th inst. in a delirium, conceiving his house to be on fire, threw himself out of a two story window, and by the fall broke both of his legs above the knees, and received other injury. His life is despaired of.

A Challenge.—A Virginian proposes a wager of five hundred dollars, that he will exhibit, at the Maryland Cattle Show, which may be held near Baltimore in the year 1824, a native Bullock of Virginia, of greater nett weight than any that can be exhibited at the same time and place, by any New-Yorker, whose Bullock shall be a native of that State.

BY T. C. FESSENDEN.

Some of the following lines are altered and paraphrased from certain passages in a poem, entitled, "THE EFFECT," the production of Dyer, a British poet.

The advantages of industry illustrated; houses of labor recommended, and vagrants invited to accept of such asylum.

Not only man but nature lives by toil,
Beast, bird, the elements, and rolling worlds
Exist by action; nothing lies at rest
Save sluggards, death and ruin. Man is born
To care, and toil must nurture him, or else
His powers and faculties will never ripen;
Nonage will on the heels of dotage tread,
And the poor biped will remain a child
Through every stage of sublunary being.
Wise states of yore, observing this, ordain'd
That rich and needy, high and low, be doom'd
Alike to labor; and they often call'd
The rugged chieftain from his plough and fold,
From ruling brutes to rule the commonwealth.
Utiity was then the test of merit
Throughout all ranks. Then exercise gave health,
Corporal strength, and force of intellect.

We owe to toil whatever raises man
Above the wildest quadruped that roams
The wilderness. Corn, wine and oil,
The cottage and the dome, the joys of life,
Are fruits of industry. What nature yields
(And she performs her part) are mostly rude
And raw materials, to be form'd by skill
And industry, which fashion them to wealth.

To idle want and vagrant vice, the means
Of doing good true charity supplies,
Means wherewithal to benefit themselves,
And serve the common weal, by useful toil
In every village charity should raise
HOUSES OF LABOR—seats of kind restraint
For those who wear out life in fruitless sports,
And idleness, the harbinger of want;
Who each employment sedulously shun,
Which honest wealth might yield, and something due
By all to all, and public weal subserves.
Ye vagrant poor, who ramble to and fro,
Like gipsy-hordes, and him who tempted Job,
Who haunt the dwellings of the diligent
For sustenance unearn'd; who ramble wide
From house to house, with mischievous intent,
Feigning disease, with false and woful tales
Of dire distress, and ye whom real want
Has howled like rushes, which the torrent sweeps—
Who tread the rough high way without an aim,
With painful step, and bitterness of heart,
Ghaunt children of affliction, do not shun
The path which terminates in all the bliss,
Which charity can with discretion yield;
Let not false pride predominate, but turn
Your step-sworn foot to gentle friendly toil.
The loom awaits you, and the spinning wheel,
The adze, the awl, the implements of art,
Which pled with diligence will put dull care
And darning reminiscences to flight.
Here may you rest and place your pillow here,
Safe from the peltings of the pitiless storm,
Pure beverage, wholesome viands shall be yours—
To heal each sickness the physician waits,
And priest invites to give your Maker praise.

Regard the world with cautious eye,
Nor raise your expectation high,
See that the balance-scales be such,
So neither full nor empty too much.

Support of Paupers.—The system of having a work-house, with land adjoining, where the paupers may do something to support themselves, has been adopted in many places with the most satisfactory results. The Christian Register says that the managers of the pauper establishment in Cambridge have paid \$80 into the town treasury, after defraying all expenses of the establishment for the past year.—*Pittsfield Sun*.

From the Trenton Emporium.

March of Improvement.—A dozen years ago only, and a trip from New-York to Norfolk, was considered an undertaking of no small magnitude—a journey of very uncertain termination—now you step on board the steam boat in New-York, and are safely landed in Norfolk in a couple of days. Formerly, before a voyage to Havana, there was an invariable closing of contracts, arranging of business, drawing out and executing of wills, mournful farewells and letters written back by the pilot boat—now it is a neat little pleasure jaunt—its hardly worth while to bid good bye—just going down to Havana. And some think we shall soon travel over land as nicely as we do over water—Oliver Evans used to say that the time was coming when a trip to Pittsburg would be but a pleasant excursion—and when steam should supply the place of horses.

Recipe for making a pound of Fire Wood save a cord.—From the end of a small, straight grained stick, saw off a pound, and split it into as many pieces as it will admit for the purpose designed. Make each piece into the form of a wedge, and place one of those wedges between the casing and the top of the lower sash, wherever the wind enters between the sashes.—*Boston Gazette*.

Singular Phenomena.—About two tons of refuse iron, consisting of filings and shavings, were deposited in a wooden store near this village. By accident, a few quarts of linseed oil was spilt on the heap. In about three weeks after this occurred, a person walking over the mound perceived it to be very sensibly warm. In opening it, a great part of the interior was discovered to be heated to redness! The iron was free from sulphur, which is known to inflame spontaneously with iron.—*Taunton, Ms. paper*.

Corsicaurum.—A new mineral earth has been lately found in Corsica, thought to be impregnated with particles of gold. By chemical operation, vases have been made of it for table services, and it is found to vie in color and lustre with the finest vermilion. The name of Corsicaurum has been given to it; it has the property of not discoloring white stuffs, which is not always the case with gold, the most purified and refined.—*N. Hampshire Repository*.

The celebrated Englishman, Capt. Cochrane, who is famous both in and out of Europe, for his long excursions on foot, and has been for two years engaged in such a tour in Siberia, to discover whether in the Northern Latitudes there is any connection between the continents of Asia and America, has married in Kamtschatka, a native of that country, and is now on his return. He has not found any junction of the two Continents.—*Hamburg paper*

NEWPORT, (R. I.) Dec. 4.

The remarkable propensity of cats, in sucking the breath of infants, has often been spoken of, and has been considered by many as fabulous; but an instance occurred in this town, last week, which should put parents upon the guard against this danger. The mother had the infant in the care of a domestic—on her return, she was informed that the cat was found with its two fore paws fast encircling the child's neck, and its mouth in that of the child, which was nearly suffocated; and great exertions were necessary to extricate the helpless little sufferer from its perilous situation. The story was not much heeded by the mother, but what was her horror on being awaked in the night, by the convulsed struggling of the infant, and finding the same cat, in the same position, and the child again reduced to nearly the same extremity! The cat was immediately thrust out of the window—and so much eagerness did she manifest to return to her victim, she brooded through a pane of glass to effect her object. It was not until the cat had made the third attempt on the following day that she was put to death.

From the Westchester Herald.

Rain.—Few persons are aware of the immense quantities of rain which descend from the clouds in a certain space of time. Last Wednesday night, it was ascertained that the rain fell to a depth of 8 inches. Now it follows, if we suppose our county contains 500 square miles, that the rain was equally plentiful throughout the county, that nearly 1200 millions of hogsheads of water must have been poured upon the surface in that night only. Hence if we calculate the Tappan sea to cover a surface of square miles, and that the water is 24 feet deep upon an average throughout the whole body it appears, that nearly as much water was discharged from the clouds on Wednesday evening in this county alone as would fill the whole space occupied by the Tappan sea. This estimate may be amplified to any extent, and it proves how vast is the divine power and benevolence; and how trifling and contemptible are all the works of man in contrast only with the most ordinary acts of God in his provident government of the world!

From the Farmer's Calendar for 1823.

Useful Hints.—"Sir, asked a young man, would you be so kind as to measure this load of wood? My father has sold it to Mr. Crispin, the shoemaker. Father says there is a good cord, and Mr. C. says no, and they have left it to you." "Well my lad, there is just about six feet of it. It is almost every stick too short, and I can see there are some hollow places in it, and now it is a rotten stick tucked in."

Who comes here! Oh 'tis Capt. Thrifty! He never goes to a tavern or grog-shop to lay stores for Sunday. Whatever he does is done quickly and then he is off. He treats no friend at the tavern or retailer's cup. No morning drinks, or eleven o'clocks for him. He has plenty of good beer and cider. He never contrives more than he can pay in season. He pays interest, because he pays the principal and thus saves the expense of suits, and the vexation contending with his neighbor.

DISEASES OF CATTLE.

BY THE EDITOR.

In our paper of Nov. 16th, No. 16, p. 126, we proposed "to give articles from the most approved authors, relating to the diseases of cattle, horses, swine, sheep, &c. and we now proceed to carry that proposition into effect.—We would premise, however, that we have no knowledge of this subject derived from practice, and shall merely select such articles as we think may prove useful, from treatises, which appear to have been correctly and judiciously written, and have met with the approbation of men of science on both sides of the Atlantic. We shall sometimes alter the language of the authors, whose ideas we may adopt, for the sake of brevity, and to make the subjects plain to readers who are not acquainted with medical and anatomical terms; but we hope to retain the meaning whenever we vary the phraseology. We shall, occasionally, intersperse our extracts with remarks of our own, derived, principally, from conversation with practical farmers, and others, who possess the kind of knowledge which is most to be relied on, to wit, that which is derived from experience. We are fully sensible of the importance of the subject, and know that improper prescriptions may not only cause the loss of much valuable property, but may subject many poor animals to cruel as well as absurd treatment. We shall therefore assert nothing relative to the symptoms or cure for diseases of cattle which is not supported by respectable authority; and should we be so unfortunate as to lead our readers astray, it will be owing to the fallibility of the most competent guides we could find to direct our course.

The following observations by Mr. Lawrence, an English writer of reputation, might very well precede every treatise on Cattle Medicine or Farriery. "It should be considered that animals, living in a state of nature, regulated by the reason and experience of man, might be wholly exempt from disease—that their appetites, unlike our own, may be held under constant control—that their diseases result purely from the negligence or erroneous treatment of their owners. They are either exposed too much to the rigors and changes of the weather, or they are gorged with food, denied a sufficient quantity, or supplied with such as is unwholesome. Here we learn the chief causes of their maladies. LEARN TO PREVENT THEM, instead of undertaking the tedious, unsuitable, and often hopeless task of learning to cure them. I have no infallible receipts to offer; on the contrary, I wish to impress my readers strongly with the idea, that all *infallible receipts are infallible nonsense.*"

Inflammatory Fever, or general Inflammation; called also Quarter Evil, Black Quarter, or Spuil.—This disease frequently happens to young cattle, generally between the first and third year, most commonly about the second year of their age. It appears to be occasioned by feeding them too hastily; by putting them, when in a lean state, into rich succulent pasture.

The animal when seized with this complaint,

becomes suddenly listless and stupid; he hangs down his head, refuses his food, and appears to move with difficulty. Swellings soon appear in different parts of the body, which, when pressed by the finger, make a crackling noise. Sometimes the joints are particularly affected; at others, the swelling appears on the back, shoulder or belly.

The disease attacks rather suddenly, and often proves fatal, particularly when proper remedies are not speedily employed. Bleeding is the first remedy, and must be proportioned to the age and strength of the animal; perhaps from three to four quarts will generally be found sufficient. The blood should always be measured. The following purgative should then be given.

Aloes	-	-	-	3 dr.
Potash	-	-	-	2 dr.
Sulphat of Soda [Glauber's Salts]	-	-	-	6 oz.
Warm Water	-	-	-	1 pt.

Mix for one dose.

This dose will generally be found sufficient for an animal of two year's old. Should the disease occur in situations, where these medicines cannot be procured, give from four to six ounces of common salt in a pint of water; the addition of four ounces of castor oil, sweet oil, or even linseed oil, will make it more efficacious. Should the animal be relieved, by this treatment, considerable weakness may follow; for which give the following twice a day:

Powdered Caraway seeds,	1 oz.
Ginger	- - 2 dr.

To be given in a pint of oat-meal gruel [or any other gruel] or ale.

The swollen parts, particularly if the joints are affected, should be rubbed with the following liniment:

Take of linseed oil	-	1 oz.
Oil of turpentine	-	2 oz.
Liquid ammonia, or spirit of sal ammoniac	-	1 oz.
Mix.		

Mr. Lawrence has very properly advised that a piece of short or inferior keep should be reserved, as a digesting place, where cattle may occasionally be turned, to empty and exercise themselves. This is better than bleeding, or any medical preventive; and as this disease frequently proves fatal, preventive measures should never be lost sight of.

Murrain or Pest.—These terms correspond with that of plague in the human species, (and the diseases are said to have a similar origin, to wit, in putrid miasmata,) and like the plague is attended with boils or buboes. The plague of horned cattle is said to be of a peculiar nature, and not communicable to other animals. Yet in a contagious disposition of the air, it may chance that various species of animals may be affected at the same time. The infection is first denoted by a decrease of appetite, difficulty of swallowing, shaking the head, hanging down of the ears, and dulness of the eyes. Constant diarrhoea, or scouring, fetid breath, nauseous steams from the skin, infecting the surrounding air. The blood is florid, hot, and frothy, and

the urine high colored. Roof of the mouth ulcerated. Tumors or biles are felt under the fleshy membrane of the skin; eruptions all along the limbs, and about the bags of the cows. Milk dries up suddenly. The animals groan much, and are worse towards evening, mostly lying down. These symptoms continue increasing until the seventh day, in which, generally, although sometimes protracted to the ninth, the crisis or turn takes place.

Dr. Darwin proposes, when this distemper makes its appearance, to slaughter all the cattle within five miles of the infected place, which appears to be a very harsh mode of proceeding; and although "death's a cure that never fails," such a remedy is commonly thought to be as bad as the disease. Mr. Lawrence advises, on the appearance of the distemper, to place the whole herd under the best shelter that circumstances will allow: to separate those which are in the most advanced stage of the disease, and slaughter such as good judges shall deem to be in a state too dangerous for any attempt to cure, and bury them pretty deep in the ground. In a disease so highly putrid bleeding should be moderate, yet in the beginning, he thinks it will be necessary, as also setons and rowels. "If costiveness prevail, the body must be kept open by clysters, or the most moderate purges, but a scouring is the most usual symptom. The sick-house must be sufficiently airy, yet well defended from wet and cold. Acid fumigations will purify the atmosphere of the house, and probably the fumes being inhaled by the beasts will have a favorable effect."

"The *emphysema*, windy abscess, or puffing up of the hide, filled with a thin putrid matter and foul air, which nature furnishes in the last stage, as a mean of throwing off the disease, must be opened at full length, wherever situated, and the matter discharged. The cavity to be filled with pledgets of tow, dipped in tincture of myrrh, or of an ointment composed of powdered rosin and yolk of eggs. Poultices of oatmeal, stale beer, &c. may be necessary to bring the ulcers to a proper digestion. Nitre has, of late, been successfully used in gangrenous ulcers, the cavities being filled with it. The approach of mortification is indicated by the dark and flabby appearance of the inside of the mouth, coldness, insensibility, blackness and ill scent of the dung, sanious and foul discharge from the mouth and nose, and dulness of the eyes. On the return of health, mild, cleansing purges will be necessary, but the danger of mortification must be fairly passed. The recovered beast must not be suddenly exposed to the air, but only turned out a few hours in the middle of the day, particularly throughout winter. Sudden exposure has subjected many convalescents to a vertigo of giddiness, and to consumption."

M. Sauvages, the celebrated professor of Medicine at Montpellier, was an accurate observer of this disorder, when it raged with great violence in many parts of Europe. He calculated that of twenty who were attacked by it nineteen died; that no certain remedy had been

discovered, or any effectual mode of preventive, except separating the healthy from the sick; he recommends, however, bleeding and purging at the commencement of the disorder, with sections in the dewlap. After the operation of the purgative, he considers opiates, aromatics, &c. such as caraway seeds, ginger, cascarrilla, &c. as the most proper medicines.

A writer in the Gentleman's Magazine, quoted with approbation, by Dr. W. Peck, a late learned and judicious writer on veterinary medicine gives the following directions to prevent and cure the disease.

First. Avoid the infection with the utmost diligence. *Secondly.* Trust to none of the celebrated remedies that may be proposed to you, unless founded on experience; most that have been offered by farriers are known to be ineffectual, and many of them extremely injurious. *Thirdly.* If your cattle are attacked, bleed plentifully, repeatedly, and keep their bodies open. *Fourthly.* Give them no dry meat from the commencement of the attack till the fever abates; let their mashes be thin, given warm, and very often, a little at once; keep them dry and warm. *Fifthly.* Give no warm spicy drenches, at the commencement of the disease.

The following extract from an English work is illustrative of the infectious nature of this disorder.

"A farmer in Essex, who had the distemper among his cows, invited a neighboring farmer to come and assist him in giving drenches to some of his sick cattle; the good natured man went accordingly and spent the best part of the day with his neighbor, to lend him his help in distress, little dreaming of the ill consequence of being so many hours with the diseased cows; so much of the infectious effluvia adhered to his clothes, that, as he was walking home, though a mile and a half, through a field in which several of his cows were feeding, he no sooner entered, but they left off grazing, ran to the further end snorting and flinging up their noses as though they smelt something very disagreeable; and so indeed it proved to them, for the very next day, many of them fell sick, and died in a few days."

(TO BE CONTINUED.)

From the Plough Boy.

MR. SOUTHWICK,

It appears from our statute books, that our state has appropriated about one and a half millions of dollars, for the benefit of colleges and academies. This amount has gone almost exclusively for the education of young men designed for the professional and mercantile classes. And what has been done for the education of Plough Boys,—whose productive labors are the life-blood of our commerce, the sinews of our manufactures, and the food and raiment of our professions? Comparatively nothing. It is ardently to be hoped, that the example of Virginia, prompted as it is by the intelligent mind of a Madison, will awaken our legislature to a just sense of the importance of establishing a school of agriculture. I have no doubt but it would tend, more than any other measure, to improve our husbandry; and that the increased tolls upon our canals, which it would cause, by increasing the productions and profits of our farms, would remunerate the state, in ten years, the whole expense of the establishment.

You have said there is at least *one* establishment of this kind. I presume you allude to that

of M. Fellenburgh, at Hofwyl, in Switzerland. This school affords a demonstration not only of the practicability, but of the usefulness, of teaching, conjointly, the theory and practice of agriculture. So high has its reputation become, that many of the young German noblemen are sent to M. de Fellenburgh for instruction; and his pupils receive extravagant salaries as managers upon many of the great estates on the continent. I advise you to procure and publish an account of the institution. It may be found in one of the Edinburg Reviews; I think, in the volume for 1817. There is also a report of it, made to the Emperor of Russia, in 1814, by the Count de Capo d'Istria; a pamphlet by M. Pictet, of Geneva, and considerable said in its commendation by Mr. Brougham, in a report to the commons of Great-Britain, made in 1818, on the subject of education. Mr. B. spent some time at Hofwyl. But this is not the only school. In a volume of recent travels through Hungary, Dr. Bright enumerates six or eight, and says there are others, which have been established in the Austrian dominions, by the government and by individuals, on the Hofwyl plan. Accum, the well known chemist, has recently received an appointment in a similar school, from the King of Prussia.

But why seek for European precedent? We have a double inducement for such a school here. It will give us good statesmen as well as good farmers. We want farmers whose education will qualify them to speak in our legislative halls, to draft bills and reports, and to discharge the duties of any of our public offices. We want the yeomanry of our state to possess the influence which their numbers and republican virtue entitle them to; and we wish to instruct them, that their influence may be directed to public good.

COLUMELIA.

On the means of promoting the growth of Young Fruit Trees, particularly in grass land. By the Rev. Mr. Germershausen.

From the Transactions of the Economical Society of Leipsic.

When young trees stand in grass-land, or in gardens where the earth is not dug up every year around them, and freed from weeds, they do not at first increase properly in growth, and will not thrive so well as those which have been planted in cultivated ground. It has been remarked also, in orchards, that the more the ground becomes grassy, and, as it were, converted into turf, the fruit is smaller and not so well tasted. The latter circumstance takes place particularly with regard to plums.

Having planted several young plum trees, I covered the ground, for some years, around the trunks, as far as the roots extended, with flax-shows,* by which means these trees, though in a grass-field, increased in a wonderful manner, and far excelled others planted in cultivated ground. As far as the shows reached, the grass and weeds were choked; and the soil under them was so tender and soft, that no better mould could have been wished for by a florist.

When I observed this, I covered the ground with the same substance, as far as the roots extended, around an old plum tree, which appeared to be in a languishing state, and which stood

*Shows are the refuse of flax when it is scutched or hackled.

in a grass field. The consequences were, that it acquired a strong new bark; produced large and better tasted fruit; and that those young shoots which before grew up around the stem and which it was every year necessary to destroy, were prevented from sprouting forth, and the covering of flax-shows impeded the free access of air at the bottom of the trunk.

Last year I transplanted from seed-beds, into the nursery, several fruit trees; the ground around some of which I covered, as above, with flax-shows. Notwithstanding the great heat of the summer, none of those trees where the earth was covered with shows, died or decayed; because the shows prevented the earth under them from being dried by the sun. Of those trees around which the ground was not covered, as before mentioned, the fourth part miscarried; and those that continued alive were far weaker than the former.

The leaves which fall from trees in autumn may also be employed for covering the ground, in like manner: but stones, or logs of wood, must be laid on them, to prevent their being dispersed by the wind. In grass land, a small trench may be made around the roots of the tree, when planted, in order to receive the leaves. If flax shows are used, this is not necessary; they lie on the surface of the ground so fast as to resist the force of the most violent storm. The leaves which I have found most effectual, in promoting the growth and fertility of fruit trees, are those of the walnut tree.—Whether it is, that, on account of their containing a great abundance of saline particles, they communicate manure to the ground, which thereby becomes tender under them; or that they attract nitrous particles from the atmosphere—or that, by both these means, they tend to nourish the tree, both above and below.

Those who are desirous of raising tender exotic trees from the seed, in order to accustom them to our climate, may, when they transplant them, employ flax-shows with great advantage. This covering will prevent the frost from making its way to the roots; and rats and mice, on account of the sharp prickly points of the flax shows, will not be able to shelter themselves under them.

Tan or the refuse bark which has been used by tanners, has been recommended for the same purpose for which flax shows are advised as above. Tessier's Annals of Agriculture advise to use the breakings or refuse of hemp in the manner above directed. Wood ashes and slacked lime are likewise stated to be useful, not only for manure, but for the destruction of insects. It would be well if trials were made of all these substances, on different trees in the same orchard, and the results of such trials noted and published for the benefit of the community.—*Ed. N. E. Farmer.*

From Sinclair's Code of Agriculture.

Rollers.—The roller is the most useful implement for breaking hard clods expeditiously, and smoothing the surface of land when in tillage, ever yet invented. It is likewise of use to grass lands laid down for hay; and heavy rollers would prevent those ant hills, by which so many pastures are deformed. Rollers are

made of various substances; as wood, freestone, granite or cast iron; but on the whole the two latter are to be preferred. It is of importance, that the weight of the roller should be in proportion to the surface on which it is to be employed. The best plan, is that of having two rollers, each about two feet and a half in length, and both placed in one frame, so as to roll clear of one another. This is the most suitable both for corn crops and sown grass, as it neither tears up the tender soil, nor injures the young plants. Besides the labor in turning is much less severe on the frame and on the cattle. Every farm ought to be provided with rollers of different diameters and weights, so as to suit the several purposes to which they are destined; those of a small diameter are generally applied to land in tillage; and those of a large diameter, with double shafts, to grass land. Heavy rollers are of great use, for destroying worms, lugs, and other vermin in the soil.

An intelligent farmer maintains, that if draining is the first, manuring the second, and cultivation the third, rolling ought to be considered the fourth principal operation in the processes of agriculture.—Its importance indeed, is becoming more apparent, and new advantages are derived from its use both on arable and on grass lands.

Wheat should always be rolled in the Spring, after frosts, as it makes the soil adhere more closely to the roots of the plants, encourages vegetation and strengthens the stems, and renders the grain more perfect. When any crop is sown with artificial grasses, rolling is particularly necessary, to make an even surface, bruising all clods, and pressing down any stones it may not be thought necessary to carry off, to facilitate the future operation of the scythe. Mats in a light soil, may be rolled to advantage, immediately after the seed is sown, unless the ground be so wet as to cling to the roller. After turnips are sown in drills, they ought to be immediately rolled, to make the soil compact, and to promote their speedy germination. Not only for turnips, but for all other crops, rolling, particularly during the night, is found to be an efficient means of destroying slugs, snails, the wire worm, and other vermin, so destructive to young plants. Flax ought to be rolled immediately after sowing; it makes the seed vegetate equally, and prevents after growth; the bad effects of which are visible in every step of the process for dressing flax.

The other advantages for rolling arable land are, that it renders a loose soil more compact and solid. This encourages the growth of plants, by pressing the soil to their roots. It likewise keeps in the moisture, and prevents it from penetrating. When the soil is worked up lightly, moisture either filters through too quickly, or is easily evaporated. In a dry season this may occasion a very material difference in the crop, more especially in a light soil. Rolling is executed to most advantage across the direction of the ridges, because more adapted to ensure full benefit to the furrows which otherwise may not be properly gone over.

When a large field is to be rolled, a number of rollers ought at once to be set at work, otherwise an opportunity may be lost never to be regained.

It has long been considered, as an incontrovertible proposition, and approaching to the na-

ture of an axiom, "That whoever could make two ears of corn, or two blades of grass, to grow upon a spot, where only one grew before, would deserve better of mankind, and do more essential service to his country, than the whole race of politicians put together."

There never was a greater instance of sophistry, than this doctrine of Swift's, who seems not to have been at all aware, of the immense benefits, conferred upon agriculture, by a judicious system of civil policy. In fact, the prosperity of agriculture, depends upon the politician. The better and more equitable the civil policy of a country, the more perfect will its agriculture become. Those politicians or statesmen, therefore, who, by removing every obstacle, and furnishing every proper encouragement to agriculture, promote its advancement, have a higher claim to the gratitude of mankind, than those who have merely performed a secondary or practical part, which part, they never could have performed at all, but under the protection of wise laws, regularly administered, and executed with impartiality and vigor.—*Ibid.*

Rules to be observed regarding the Improvement of Waste Lands.

In the cultivation of wastes, the following rules are laid down by the most successful improvers.

1. Not to put in practice any scheme of improvement, without the fullest deliberation, nor without the command of an adequate capital.

2. Not to begin on too great a scale, nor until, by experiment it be found, that the design is suitable to the soil, situation and climate.

3. When the intention is to cultivate peat-moss, not to begin cropping, till at least one season after the drains are completed, and the soil thoroughly reclaimed from superfluous moisture. In flow or spongy mosses, a longer time is necessary, and it is desirable to expose the soil to the action of the atmosphere, during the frosts of winter.

4. To plough or delve peat-moss in autumn, that it may be effectually exposed to the winter frost and rains, and not to the summer's heat, which hardens it, and prevents its decomposition.

5. Whatever is done, to do it effectually; not to think of laying on four acres, the manure necessary for three; nor the lime, chalk, earth, clay, sand or gravel, upon two acres, that should be employed in covering only one.

6. To carry on the improvement of waste lands, without encroaching upon the dung necessary for the improved part of a farm, as dung ought never to be brought from a good soil to lay upon a bad one. Unless dung therefore can be procured from a neighboring town or village, it will be better to leave the lands in their natural state, except in cases where the soil, by being pared, burnt, limed, or marled, or covered with chalk, clay, earth, &c. will pay the expense of the improvement.

7. The last rule is, to lay down land, improved from waste, more especially in high and bleak situations, as soon as possible into grass, and to retain it in that state as long as it is tolerably productive. For though grain and roots may be cultivated on waste lands, when properly improved, yet grass pastured, particularly by sheep, is principally to be depended on for improving all weak soils, in barren districts. In

such cases, it is from grass alone that remuneration can be looked for by the improver of waste lands. Even though soils of this description do not produce grass in much abundance, or of good quality, yet when in pasture they produce something, and a stop is put to farther expenditure.—*Ibid.*

Ditching.—When bushy ground, full of strong roots, is to be ditched, the Rev. Mr. Eliot wisely recommends beginning the ditch in the winter, when the ground is frozen two or three inches deep. The surface may be chopped into pieces by a broad axe with a long helve, and the sods pulled out with an instrument made like a dung croom. The farmer may probably hit upon a good time for this work in December, when there happens to be no snow, and when it will not interfere with other farming business. The lower part of the ditch may be done in the following summer, or autumn. In a free and firm soil, a ditch may be begun with a plough, drawn by an orderly team that will keep to the line. This saves labor.

To make a ditch straight, and equal in all its parts, it is recommended that the work be regulated by a frame of slit deal, nailed together, to the exact size of the intended ditch. It may be a rod or more in length, and as wide as the intended ditch.—*Deane's N. E. Farmer.*

Rice Jelly.—This is one of the best and most nourishing preparations of rice, particularly for valetudinarians or convalescents. It is thus made: Boil a quarter of a pound of rice flour, with half a pound of loaf sugar, in a quart of water, till the whole becomes one uniform gelatinous mass; then strain off the jelly and let it stand to cool. A little of this salubrious food eaten at a time, will be found very beneficial to those of a weakly and infirm constitution.

Chemical Agency by the Magnet.—Mr. J. Murray states, that he had succeeded in decomposing by the magnet, every metallic salt to which he had applied it. One instance of this fact, so interesting to science, we quote for the sake of its tendency. 'A solution of *permutate* of mercury was, by the magnet, soon reduced to metallic or running mercury.'—Hence fine steel filings, magnetized, administered in syrup, will be an admirable antidote to corrosive sublimate.

London paper.

Sir John Sinclair, in his Code of Health declares that the modern art of Fencing is not only conducive to longevity, but absolutely enlarges the bones of the chest and thorax. *Locke* calls it an essential part of good education.—*Wright* on Elocution, praises it as an auxiliary to Elocution. *Chatham*, in one of his letters to his nephew, Lord Camelford, assures him, it will place his head upright and plant him well upon his legs.—*National Gazette.*

There is not an earthly beauty that I look upon, that has not something in it spiritual to me. And when my mind is fair and open, and soul right, there is not a flower I see that does not move my heart to feel towards it as a child of God. All that is, to my mind, is a type of what shall be; and my own being and soul seem to me as if linked with eternity.—*Idle Man*

TO THE EDITOR OF THE NEW ENGLAND FARMER.

Having seen in No. 16 of your paper, a request for some information respecting the cheapest and best mode of clearing heavy timbered new lands—I send you the following: From long experience and strict observation, I am of opinion that the generality of people involve themselves in more than twice the labor and expense necessary for the want of prudent care and attention in felling their timber. Most farmers when they begin in the woods, are in a hurry to have some land cleared; they hire their chopping done by the job, and such choppers, so hired, are only interested in doing it as fast as possible. They generally cut the smallest timber first, fall the trees promiscuously in all directions the way they will go with the least chopping, and the largest trees the last. Then after it has lain a year to dry and the fire been through it, to burn the small brush, the logs lay in all directions; the smaller first under the larger, and it will then be twice the labor to clear it off, that it would be if nothing had been done, provided they would follow the following directions.

1st. Take a view of all the large trees, and see which way they may be felled, for the greatest number of smaller trees to be felled along side, or on them. After felling the large trees, only lop down the limbs; but all such as are felled near them, should be cut in suitable lengths for two men to roll and pile about the large trees, by which means they may be nearly all burnt up without cutting into lengths or the expense of a strong team to draw them together.

2d. Fell all the other trees parallel and cut them into suitable lengths that they may be readily rolled together without a team, always cutting the largest trees first that the smallest may be loose on the top to feed the fires.

3d. On hill sides fell all the timber in a level direction, then the logs will roll together, and if the trees are felled down hill, all the logs must be turned round before they can be rolled, and there will be stumps in the way.

4th. By following these directions two men may readily heap and burn most of the timber without requiring any teams, and perhaps the brands and remains of the log-heaps may all be wanted to burn up the old fallen trees. After proceeding, as directed, the ground will be clear for a team and sled to draw the remains of the heaps where they may be wanted, round the old logs. Never attempt to either chop or draw a large heavy log until the size and weight is reduced by fire.

The more fire-heaps there are made on the clearing, the better, particularly about the old logs, where there is rotten wood.

The best time of the year to fell the timber, in great measure, depends on the seasons' being wet or dry. Most people prefer having the timber felled in the month of June, when the leaves are of full size. Then by spreading the limbs and brush over the ground (for it should never be heaped) if there is a very dry time the next May, fire may be turned through it, and will burn the leaves, limbs, and top of the ground so that a very good crop of Indian corn and pumpkins may be raised amongst the logs by hoeing; after those crops come off, the land may be cleared and sowed late with rye and timothy grass, or with oats and timothy in the

spring. If what they call a good burn, cannot be had in May, keep the fire out until it can be had in some very dry time in July or August; then clear it off and sow either wheat or rye and timothy, harrowing several times, both before and after sowing, for after the fire has been over the ground, the sod of timothy should be introduced as soon as the other crops will admit, to prevent the briars, elders, fire-cherries, &c. from springing up from such seeds as were not consumed by the fire.

The timothy should stand some 4 or 5 years, either for mowing or pasture, until the small roots are rotten, then it may be ploughed, and the best mode that I have observed, is to plough it very shallow in the fall; in the spring, cross plough it deeper, harrow it well and it will produce a first rate crop of Indian corn and potatoes, and the next season produce the largest and best crops of flax that I have ever seen and be in order to cultivate with any kinds of grain or to lay down again with grass.

These directions are to be understood as relating to what is generally called *Beech Lands*—and the chopping may be done any time in the winter, when the snow is not too deep to cut low stumps, as the leaves are then on the ground. By leaving the brush spread abroad, I have known such winter choppings to burn as well in a dry time in August as that which had been chopped the summer before.

SAMUEL PRESTON.

Stockport, Pa. Dec. 11, 1822.

Report of the Committee of the Hillsborough (N.H.) Agricultural Society, on Agricultural Products.

The committee, appointed to view, on the ground, field products of competitors, have performed the duties of their office agreeably to their instructions. Of eleven, who were chosen as a Viewing Committee, only seven attended to the business of their appointment, viz. Peter Woodbury, William Riddle, Ezra Abbot, Porter Kimball, Phillip Brown, Joseph Cochran, Esqrs. and Humphrey Moore. They began their rout on the 29th July, and completed it on the first of August. They beg leave to make the following Report of their doings.

They commenced their business by viewing the crops and farm of Dr. Thomas Eaton, of Francestown. The products of his fields were all good. But his most distinguishing crop was Wheat, of which he had four and a half acres, and, for the present year, was excellent. The Committee awarded him the first premium for his WHEAT CROP. His POTATOES, growing on 13½ acres of ground, were well cultivated, and appeared very promising. For these he was considered to be entitled to the second premium. His Indian Corn and French Turnips were very luxuriant; but upon comparison with the same kind of crops of other competitors, they were not esteemed deserving an award.

The farm of Dr. Eaton, containing 280 acres of land, is made up of hills and valleys, and is generally of a warm, free soil. It is well proportioned in respect to woodland, pasturage, mowing, orcharding, and tillage. Order and judicious management marked every department of his Agricultural business. Every thing appeared to be done with calculation and for profit. The extent and conveniences of his barns, out-houses, and the order of his house, shew how delightful may be the situation of a

farmer. He consumes the whole of his crop in his family and in his stock; and, sometimes in addition makes considerable purchases for consumption. That this method should continually add to the fertility of a farm, is not doubted; but whether it will give the greatest net profit for any given course of years, is submitted to Agriculturalists who love to make experiments, and also love to make calculations.

The Committee next viewed the crops of Messrs. Folsom and Whittle, of Deering. Their OATS, growing on 2½ acres of ground, were generally very heavy, and were considered worth of the premium offered for the best crop of the species of grain. Their Potatoes, 4½ acre looked very well, but did not excel. Their Wheat, of which there were four acres, was very good, and would have received a premium had not other fields, in competition, been better. Their farm contained about 400 acres of good land. The soil was strong; but from its closeness, it appeared to be better adapted generally to grass than to grain. The Committee were a little surprised to see, on such a good and extensive farm, keeping 40 head of cattle and 70 sheep, only 2½ acres of Indian Corn, and no more than ordinary luxuriance. But the great article of this farm and the source of wealth to its owners were stock; which gave evidence of the superior quality of the breed and the excellence of their keeping. The farm was well managed, and distinguished for some of its well built and permanent fences.

The farm of Mr. William Whittle, of Weare contains about 200 acres of land of various qualities. His Wheat crop, covering four acres of ground, appeared very well. It has suffered from the early drought. On comparison, it could not command a premium. Seven acres of his ground were planted with Indian Corn. The field was a pine plain; the soil very light; the manuring small. Considering these circumstances the crop commanded attention. The third premium on INDIAN CORN was awarded to him. His farm generally appeared to be under a profitable process of cultivation.

Mr. Peter McNeil, of New-Boston, has a farm generally hard and uneven. By industry he makes it fruitful and profitable. He offered an acre of WHEAT for examination. The crop was very good, and it was esteemed worthy of the second premium.

Mr. Jacob Hooper, Jr. of New-Boston, offered several crops for examination. They were all good, but none was entitled to a premium excepting his FLAX, for which the first award was made.

His farm, of 200 acres, lies principally on a beautiful hill, whose ascent is easy, and whose soil, though not of the richest quality, was very feasible. His fields were laid out with accuracy and cultivated with the greatest care. The fences were exceedingly well built, and of the most durable materials. Not a bush infested the walls, or headlands; nor a weed of a finger's length encumbered his fields. Not a squirrel or a mouse, could find rubbish enough for a lurking place, from which they might sally forth to make their depredations upon the crops. Ceres might here plant her throne, and rejoice at her success, that she had found one spot on earth where her laws were strictly obeyed. The barn, the granary, and the work shop were in perfect order. The

ols were in repair, and were where they ought to be. The door-yard was free from imbrances. Not a chip was out of place. The parlor of the hogstye, whose walls and floor were made of well prepared granite, was neat enough for the study, or office of any professional gentleman in the county. The house and the good order of the house, completed the system of neatness and correct management.

The farm of Mr. John Fairfield, of New-Boston, is situated on the east side of a large hill, and is naturally rough and rocky. The acre, which he selected for POTATOES, was a light soil. The crop was luxuriant, and the Committee awarded him the first premium. His other crops appeared very well; and his farm, though generally hard and rocky, gave evidence of industry and good management.

Doctor Matthias Spalding, of Amherst, entered his name as a competitor on Wheat, Indian corn, and English Turnips. His Wheat had suffered by the drought, was harvested, and the committee could not examine it. His field of Indian Corn, containing about three acres, was very good. The soil was warm, and light, and well cultivated. The crop was entitled to special notice; but the excellence of other Corn crops prevented it from receiving a premium. His ENGLISH TURNIPS were in a flourishing condition, and promised a large crop. For this product he was considered entitled to a premium.

His farm is small, and the principal part of it is naturally hard. When he made his purchase, much of his land was in a rude, and almost uncultivated condition. But by taking out the stones and making enclosures with good stone walls; by taking up piece after piece, and giving each a thorough cultivation, he has made a large proportion of his farm like a garden. He is proved that the science of Agriculture is adapted to practice; that hard land may be made soft; that poor land may be made rich; and that an unfruitful soil may be made productive. His general method of husbandry improves his land, while it improves his crops.

The farm of Timothy Danforth, Esq. of Amherst, is made up of various soils. His land lying on the Souhegan is very rich and fertile. The back lands are light and dry. A part of his Indian corn and a part of his oats are very heavy. His field of Potatoes were very good. His RUTA BAGA, growing on nearly half an acre, very flourishing, and promised a valuable crop. The Committee saw fit to honor these with a premium. His method of culture is improving his farm and making it more profitable.

The Committee, as they were passing from Amherst to Wilton, called on the Minister of Milford. After having made the usual examinations, they awarded him a premium for PEAS and BEANS.

They next examined the crops of Capt. Wm. Amsdell. His farm lies in Milford, bordering on the Souhegan river. He has a large tract of valuable intervale; a good proportion of arable land; and the remainder, pasturage and woodland. The farm contains a variety of soil, which is adapted to a variety of products, which is for the convenience of a family and for the interest of a farmer. His Wheat, in the fore part of the season, was very luxuriant, and promised a first rate crop; but growing on a hard land, it was greatly injured by the early

drought. His Oats, not offered for a premium, were equal to any that were examined. His field of INDIAN CORN, growing on light, warm land, was extraordinary for that quality of soil; and he was awarded the second premium. His farm is managed with great neatness and good judgment; and every thing about him denotes that he is going ahead.

The farm of Mr. James Dascomb, of Wilton, is rough, hard, and rocky. It would require an iron constitution, and a resolution, not to be broken or bent, to live upon it. On the eastern declivity of his farm, he has a field of INDIAN CORN, containing four acres. The soil is as strong as stones can make it. It appears as if the pavements of nature were broken up. Amidst this seeming wreck of rocks, the Corn is of uncommon size. Though the hills were made at a usual distance from each other, the Corn was so thick that it was difficult to walk among it. There were stalks more than 10 1-2 feet in height, and well eared. The Committee were pleased to award him the first premium; and they could only regret that it was no larger.

The Committee went next to Mr. Oliver Whiting's, of Wilton. There they examined a field of BARLEY, containing five acres. It was a fine crop. It was estimated that it would yield 40 or 45 bushels per acre. It far exceeded any other Barley crop, which was offered. The premium was awarded to him. His farm contains more than 700 acres of land. Though he is a man of but little more than 40 years of age, he has acquired the principal part of it by hard labor and good management.

The foregoing awards were made after the Committee had examined the products of all the competitors; and they were made according to the best of their judgment; and generally with unanimity. Though each competitor did not excel in every thing; yet they all excelled in something, and no one has the mortification to have his hopes blasted, nor his ambition checked.

The Committee are decidedly of opinion, that the present method of awarding premiums on Agricultural products is wisely chosen, and that it will promote the great object of our Society. There is an equal chance for all; and the members will cease to fear to strive, when they find that there is no injury attending a defeat.

The task, which the Committee has performed, though laborious, and at a season somewhat inconvenient, was a pleasant and improving one. The hospitality of a farmer's board, drawn from the resources of his own soil, was calculated to gratify the taste of men, who had a relish for a farmer's life.

The committee were not unobserving travelers as they passed from town to town. They noticed the farms, which lay within their view, and their distinguishing peculiarities. Many were excellent; and generally they were considered to be in an improving condition. It was with painful anxiety the Canada Thistle was observed on the sides of roads upon the high lands, and upon the banks of streams, lest that winged evil should visit and afflict this part of the county. Here and there a bush thrust itself through a breach in the fence; now and then an old hat or a bundle of rags looked contemptuously through a broken pane of a window, and by their looks hinted as if they would appear in our next legislature, and raise their

voice against the existence of Societies, which were established to destroy their rights and privileges.

The most prominent defect, which was observed among the farmers, was their neglect of making Manure. With a very few exceptions, they did not appear to make any more than what they could not easily avoid making. Till this defect is remedied; till manure is considered the basis of good husbandry, Agriculture will keep far behind the other arts.

All which is respectfully submitted by your Committee.

HUMPHREY MOORE, for the Committee
September 24, 1822.

From the London Farmers' Journal.

On the comparative merits of the Improved Short-Horns and Hereford Cattle.

Horsford Hall, near Leeds, Sept. 26, 1825.

SIR,

I have for a long time had an anxious wish to examine the question which has so much occupied the minds of agriculturists—*Whether the preference is to be given to the best Hereford Cattle or to the Improved Short-Horns?*

For this purpose, I last year made a tour into the north of England, and am now just returned from a similar journey of five hundred miles through Herefordshire and the adjoining counties. Nothing short of personal examination of the animals in their respective districts, and in their natural state, could give me the means of forming an opinion satisfactory to myself; whether it may be satisfactory to your readers may, perhaps be doubted; but if I give it with impartiality, it will, I hope, receive candid attention, and not be commented upon with too great severity.

The animals designated by the title of *Improved Short-horns* are few in number, and they are widely diffused, as they have obtained high prices, and have been carried into various places to ornament many stocks. They have soft, silky, and mossy hair, and are very rich and mellow handlers; handsome and gay in color; elegant in shape, large frames on very short and small bone; level and complete in all their points, and take on fat rapidly. They give a moderate quantity of milk, and do not propagate freely; they attain maturity at a very early period of life, and on this account, as well as from the extreme laziness of their dispositions, they are quite unfit for any labor.

The Herefords are more equal as a class than the improved Short-horns. Their offal is equally fine, many of them handle well, and have a very good quality of meat. They give very little milk, but breed well, and are hardy and healthy. Their color is not attractive, their dispositions are much less placid, their skins thicker and more terse; they, therefore, take on fat less freely, especially at an early age: they do not attain so great a stature in the same number of months, and have never at any period, but particularly in youth, that perfect symmetry which distinguishes the Short-horns. Their hind quarters are very frequently coarse and short; their rumps low, their heads fleshy and heavy, and their breasts scanty and defective; but their shoulders are almost uniformly fine; their neck veins full, their tanks in some few instances good, and their twists generally excellent. I found a vast number with flat sides,

very few with wide hips, and the hair of almost all was very short and harsh.

These, Sir, appear to me, upon a careful examination, to be the distinctions between the two rival breeds. I need scarcely add that I think there is a decided superiority in the Short-horns.

I have every reason to believe that on the same food, and in the same relative circumstances, the Short-horns would be as good at two years old, as the Herefords are at three. If, however, half a dozen of each were committed to the care of the same person, and brought up precisely in the same manner, the result would be highly interesting; and if they were brought up here, I would give the Herefords their food for nothing, if they were the conquerors.

I am well aware that without such a trial, there will continue to be a great difference of opinion on this question; but as my object is truth and usefulness, and not fallacy and controversy, I submit my remarks with every deference, to the judgment of your readers, not being at all anxious to enter into any defence of the opinion I have formed, if it can be proved to be erroneous, as I had no other wish to gratify, or purpose to serve, in making this laborious and extended survey of the two breeds, and in now informing you of the result, than a desire to promote the interest of agriculture.

In the mean time, till the experiment is fairly tried, I must remind your readers that the comparison is not between the excellent breed of Herefordshire and the wretched cattle with short-horns, which find their way, very undeservedly, into many parts of the south, but between the best Herefords and that select and valuable breed to which the name of *Improved Short-horns* ought to be exclusively applied.

I am your's, very respectfully,
JAMES ARMITAGE RHODES.

From the Buffalo Patriot, Nov. 26.

Satellites of Venus.—The following singular property of the plain Mirror, is new it is believed, to the philosophical world. It was accidentally discovered by a gentleman a few mornings since, and as the subject may excite much speculation, we give his account of it in his own words.—“Sitting this morning, about gun-fire, with my back to the East, the window being open, and Venus shining brightly into the room, I was surprised to observe two Satellites close to that planet reflected in the mirror which the bearer was holding before me. I turned round immediately and looked at Venus steadily with the naked eye but could not discern them. Again I looked into the mirror with the same success. I then tried another mirror, supposing that the appearance arose from some defect in the glass; but still the two luminous specks, like stars of the sixth magnitude were distinctly visible. If the existence of this extraordinary property of the plain mirror, rivaling in its powers of magnifying, nay, surpassing the first instruments in the hands of the great Herschell himself, be confirmed by the experiments of other more able observers than myself, it is difficult to say what wonderful discoveries may not shortly be made. The satellites of the inferior planets have long been a desideratum in Astronomy, and if the honor of their discovery be reserved for our new Calcutta Observatory, I shall sincerely rejoice that I

have been the humble means in the hands of Providence of pointing out the path. There is one thing that puzzles me to account for, unless we have recourse to a new and not improbable theory of optics. I allude to the circumstance of Venus not exhibiting in the mirror her present gibbous appearance, which a very ordinary telescope will show, while the two Satellites are distinctly represented in the speculum, though invisible to the most powerful instrument hitherto made. Those who are acquainted with the distinction between the rays of sensible and rays of radiant heat, will be at no loss to conceive to what I allude. We are as yet but in the infancy of optical science, and light may have many properties which we are now perhaps on the eve of discovery.”

THE FARMER.

BOSTON.—SATURDAY, DEC. 28, 1822.

ON SAVING AND MAKING THE MOST OF MANURE.

(Continued from page 151.)

In our last number on this subject, we attempted to shew that nearly all the essential constituent parts of all vegetable substances were composed of carbon, hydrogen and oxygen, combined in various proportions, together with azote, which last is found only in some few species of plants. These four bodies, or different kinds of matter, by being differently combined, form the vast variety of vegetable products, which appear to possess not only very different, but opposite qualities, such as sweet, bitter, sour, oily, resinous, glutinous, wholesome, poisonous, &c. &c. As these ideas are probably new to many of our readers, although undoubtedly of great importance, and indeed indispensably requisite for all who would understand the rudiments of the science of agriculture, we shall still farther enlarge upon them. This we are the more readily induced to do on account of the season's inviting to protracted discussion, and the winter evenings presenting leisure both to our readers and ourselves, which might be devoted to less laudable and more unprofitable employments. Besides, we do not give any credence to the maxim of the poet, who says,

“Brevity is always good,
If we are, or are not, understood.”

On the contrary we think, when any matter of science requires to be elucidated, and its first principles explained, in order to pave the way to results of practical utility, it is better to give “line upon line,” and run the risque of being censured for redundancy, than to adopt a style more nervous and concise, but less intelligible, and not so well adapted to the capacity of common readers.

A little more or a little less in the proportions of the compounds of carbon, oxygen and hydrogen, causes the wonderful variety of vegetable products. Thus “gum and sugar contain nearly the same principles, and starch differs from them only in containing a little more carbon. These three products are convertible into each other. Thus, in the ripening of grain, the sugar conveyed into it by the sap vessels, coagulates into starch; while in malting the converse takes place, and the starch in grain is converted into sugar, from which ardent spirit results. Part of the carbon combines with oxygen, and escapes in the form of carbonic acid, while the remaining hydrogen and oxygen unite to form alcohol.”* Sugar contains, according to Lavoisier, in 100 parts,

28 carbon,
8 hydrogen,
64 oxygen.

Starch, according to Gay Lussac and Thenard, contains,

Carbon, with a small quantity of saline	
and earthy matter,	43,55
Hydrogen,	6,77
Oxygen,	49,68

Now if we could take from the carbon in starch as set down above 15,55, that is from 43,55 take 15,55, there would remain

If we could add to the hydrogen of starch 1,23, or to 6,77 add 1,23 we should have

If we could add to the oxygen in starch 14,32, or to 49,68 add 14,32, we should have

Thus a little adding and subtracting from the constituent parts of starch, converts starch into sugar, another vegetable products are capable of being altered or converted from one to the other by similar means. This nature often performs, but art is generally baffled in the attempt. De Saussure, however, has succeeded in converting starch into sugar by boiling the former in water with sulphuric acid, and it is possible that other vegetable products may be conducted through analogous changes, artificially, by chemical processes yet undiscovered. It will not appear at all incredible that a mixture of simple substances should form compounds very different in their properties from the substances before mixture, when we reflect that by melting together potash and sand, glass is produced, and mixture of muriatic acid [spirit of sea salt] and soda both very corrosive, forms so mild and salutary a article as table salt.

Barn-yard manure, and other animal and vegetable manures, are composed of the same constituents, viz carbon, oxygen and hydrogen, as the plants which they nourish. Vegetable or animal substances are of no use as long as those particles or atoms remain locked together, or attached to each other. The putrefactive process unlocks or lets loose their component atoms and they immediately commence wandering in, air poisoning the atmosphere, unless they light of some substance which has power to absorb them. If the atoms are taken into the lungs of man or beast, the animal receives an injury, which, though perhaps the time not perceptible, is not the less real. If, however, they are taken in by the absorbent vessels of plants, either in their roots or leaves, the plants convert to their own uses such particles as their necessities may require, and the floating atoms, perhaps recently released from a dead vegetable or animal, become a part of a living plant. It is therefore incumbent on an enlightened agriculturist to seize the vagrant atoms, and either present them as food for growing crops, or treasure them up for the use of future crops.

The absorbent substances which may be used to advantage for retaining and hoarding up the gases, which constitute the food of plants, are principally WATER and EARTH. Water not only dissolves solid bodies such as salt, sugar, &c. but likewise attracts and retains in solution gases or steams, such as rise from dunghill in a state of fermentation. Ammonia, or the volatile alkali, is one of the products which arise from the decomposition of all animal or vegetable substances. When uncombined with water, or any other substance, it exists in a state of gas, and is then so extremely volatile as to exhale at any known temperature. Its volatility is diminished in some degree by combination with water. That fluid has the power of taking up and condensing nearly 670 times its own bulk of ammoniacal gas, or volatile alkali. Carbonic acid gas, which also arises from the putrescence of de-

* *Agricultural Chemistry*

ing bodies, is absorbed by water, which combines several times its bulk of that gas. When water impregnated with these gases it supplies food to plants in great abundance. If we pour water on a heap of stable or cow dung in a state of fermentation, it flows out at the bottom altered in its color, taste and smell. It becomes impregnated with new substances which it has gathered in its passage through the dung, and holds in solution the results of the decomposition; and if it be deeply black and putrid it is a certain indication of its being entirely saturated. To suffer this, therefore, to run off without any care or trouble, is most culpable mismanagement, and a flagrant violation of the soundest maxims of rural economy. A putrescent stream is the very essence of manure, and should either be scrupulously confined within the limits of the dung hill, or conveyed to fresh earth that may impart its nutritive qualities."

The use of water as an absorbent and solvent for manure, is well understood in Europe. "The farmers of Switzerland consider liquid manure as the most efficacious of any, and thence, after the dung is fermented, they dilute it in water, and the liquid alone is carried to the field, and scattered over it. The earth immediately imbibes the liquid, which soon reaches the roots of the plants, and causes a rapid vegetation; whereas it is a long time before dung, in a solid state, fertilizes the soil. The straw that remains, after the dung is thus washed, is applied as manure for potatoes."*

If water is capable of holding the finest and most nutritious particles of manure in solution, it must be a very wasteful practice to suffer manure heaps to be washed by every shower, and the drainings to be conducted into the highways, to flow into a neighboring brook, or what is equally, and in some instances more injudicial to the interest of the farmer, to make a part of the land so rich as to be unproductive, or at most to yield little but rank weeds, and perhaps grass which grows before it is half grown, and is wholly or at least partially rotten before it is ripe.

Hints as to the Agricultural States of the Netherlands, page 67. Lord Kaimes likewise recommended liquid manure.

(TO BE CONTINUED.)

EVERLASTING PEA, *Lathyrus latifolius*.

A person living, it is believed, in the State of New York, some time since advertised a quantity of Everlasting Pea for sale. A small quantity of said peas are wanted by a gentleman in Boston for seed. They might be forwarded to the care of the Editor of the New England Farmer, Rogers' Buildings, Congress Street, Boston, or to some other person in Boston, at the option of the owner. Information, stating where those peas may be had, the price, and readiest mode of conveying them to Boston, would confer a great favor. If the Editor of the Plough Boy would be so good as to give notice of this request, and make it the subject of a paragraph in his useful paper, he would very much oblige
The Editor of the N. E. Farmer.

FARMER SUMMARY OF NEWS.

CONGRESS.—Nothing of great general interest has been transacted by this body. Private petitions, relatives in their incipient stages, and calls on different departments for information, have occupied almost exclusively the attention of both Houses. They appear to be getting their tools in order, and will probably go to work as soon as the Christmas holidays are over.

A vessel arrived at New York on the 23d inst. brought London papers to the 6th and Liverpool to the 8th of November. The accounts of the Greek victories are

confirmed. It appeared that 15,000 men had been landed at Napoli de Romania from the Turkish fleet, which army was subsequently taken and destroyed.

Great processions, feasting, toasting and other similar displays of patriotism have been exhibited in England on account of Mr. Hunt's liberation from prison.

There are rumors respecting some difficulties and disagreements among the principalities and powers, who compose the Congress at Verona; and something is intimated at Paris relative to the Emperor Alexander's returning to his own empire sooner than was anticipated. But these reports have a questionable shape.

The Spanish General Morillo has been arrested by the Constitutional party, and conducted, under a strong guard, to Flacencia.

Canova, the celebrated sculptor, died at Venice on the 13th of October, after a short illness.

If we may believe an official account of General Morales, the Colombian army had suffered a very disastrous defeat near Carabuya, on the 13th November.—The following is an extract from the official bulletin, which announces the battle and its results:—"At 11 o'clock, at the distance of about a quarter of a league from this point, the enemy offered us battle, in number 1200 infantry, and 100 cavalry, all veteran troops of the battalions of Boyaca, Monjos, Antioquia, and 4 companies of Carthagena. They commenced their fire by skirmishing, besides their columns en masse, which gallantly charged ours, and at less than 400 paces, our troops charged with the bayonet, and in spite of the horrible fire of the enemy they charged them with extraordinary decision, valor and enthusiasm. Altho' the shocks were bloody and the resistance great, the rebels were surrounded and completely dispersed, leaving in our hands about 1000 muskets, 800 prisoners, with 36 officers, 100 dead and 160 wounded, two colors and warlike stores. There has also remained in our possession, all the baggage of the enemy, from its chief, to that of the last soldier.—In the midst of so complete a victory, and which will always redound so honorably to our arms, we have to lament the loss of the prudent and brave Col. Don Leon Yturbe, chief of the staff of the army, and the gallant commandant of the battalion of Chasseurs, Gen. Don Josef Gomez del Arco, with 10 officers, 46 soldiers, and 70 wounded."

"For myself, observes the general, I am well, altho' two balls were fired at me by two villains, after they had surrendered, (but which only injured my clothes,) and whom, nevertheless, I suffered to live."

No official intelligence has been received, relative to the proceeding of the Congress of Verona, but the *Journal des Debats* has published an article apparently from authority, in which it was stated, that Alexander had announced to the Congress of Verona, his intention of entirely changing his system with regard to Turkey, and of employing forcible means to compel at last the barbarous government of Constantinople to make concessions.

News has lately been received from the African Colonization Society's new settlement, which is of a favorable nature. The name of this place is Liberia, it is situated on the South West Coast of Africa, near Mesurado. The place is found to be healthy, the colonists contented and prosperous, and a vessel is expected to sail soon, to add to their numbers, and furnish fresh supplies.

The Hon. Dixon Hall, a Member of the Senate of Connecticut, was lately deprived of life in a most distressing manner. Being at his factory, in Sterling, Conn. he observed a derangement in a band of one of the large drums, connected with the main shaft, and, with the intention of rectifying it, applied his hand, which was caught between the band and drum. His body was drawn with irresistible violence through an opening of ten inches in diameter, crushing the bones, and instantly depriving him of life.

A Challenge.—A "Vermont Yankee" has published a challenge to run a horse which is owned in Vermont, against any in Virginia for \$5000. "A Horse! a horse! my Kingdom for a horse!"

Several women have lost property in Philadelphia, in consequence of their reticules being snatched from them by robbers in the streets.

Quebec.—585 vessels arrived at Quebec the past season, bringing 10,471 emigrants.

The Rev. Dr. Allen, President of Bowdoin College, has now in type a work on Shipwrecks, comprising about 350 pages octavo, for the benevolent purpose of distribution among mariners.

Two thousand dollars have been subscribed in this city for the benefit of the family of the brave Lt. Allen, who was killed by the pirates.

Two lads, sons of Major C. Loppit, one aged about 12 years, the other 6, in sliding down a hill in Jewett's City, (Conn.) both seated on the same sled, were carried into the ice of an adjacent river, which gave way. The eldest caught his brother by one arm, swam to the edge of the ice, and placed him on it by a great effort. They were both rescued by a person in the neighborhood, who was attracted, by their cries, to the spot.

The Hartford Times states that a cabbage head was raised in East Granville, Mass. the past season, which measured, after all the loose leaves were taken from it, three feet 5 1-2 inches in circumference, and an apple, which weighed one pound 7 ounces.

American Wine.—A gentleman near Georgetown, (D. C.) has planted a small vineyard of about 5 acres. The vines are planted in rows, 12 feet apart, and 5 feet distant in the rows. Only one acre has begun to bear, and that produced about 390 gallons of wine the past season. A bushel of clusters of grapes yields 3 gallons of juice, and 3 vines produce, on an average, a little short of a bushel of clusters. These vines were put into a nursery in 1819, transplanted where they now stand in 1820, and began to bear in 1822.

Mr. Jonathan Smith, of this town, killed a swine last week, which he procured in April last from Captain Northey's farm in Boxford, and which then weighed about 30 lbs.; when killed, it was just ten months old, and weighed 353 lbs.—*Salem Gazette*.

An attempt was made to rob the mail on the 13th inst. near Petersburg, in Virginia. Logs were placed in the road so as to stop the stage, and three men made their appearance, one of whom presented a double barreled gun at the driver, calling upon him to deliver the mail, which the driver promised to do on condition of his life being spared. The driver caught the gun, and as the robber struggled to draw it back, struck him with a whip in the face, and by putting his horses to full speed, saved the mail.

Great Dealings.—A letter has been received from the acting Governor of the State of Ohio, directed to the Governor of the State of Pennsylvania, containing an offer from the former to exchange a map of Ohio for a map of Pennsylvania. The letter of the Ohio Governor caused a good deal of laughter in the House of Representatives on account of the trifling and trafficking nature of the proposition.

Government has purchased for 35,000 dollars, a steam-boat, which plies between Washington and Norfolk, to be employed against pirates.

The Dwelling House of Mr. Levi Scott, in Machias, with all his provisions, and most of his clothing and furniture, were destroyed by fire on the 7th inst.

William Berry, an American, was lately stabbed in the thigh by a Spaniard, at a house of ill fame in Newbern, N. C. in such a manner that he survived but a short time.

A fire broke out on the evening of the 15th inst. in Philadelphia, on Plintham's wharf, between Race and Vine Streets, which destroyed two block-maker's shops, a cooper's shop, and some other buildings, when its progress was arrested by the activity of the firemen.

State Moral Society.—At a convention of delegates from several moral societies in the state of New-York, held in the city of Albany, the 16th January, 1822, David Burhans, Esq. of the town of Bethlehem, Elisha Putnam, of the city of Albany, William Aikin, of the town of Greenbush, Rev. Thomas Holliday, of New Scotland, John L. Vile, Esq. of the village of Waterford, John Lincklaen, Esq. of Cazenovia, and Jacob Hees, Esq. of Canajoharie, were appointed a standing committee for the ensuing year.

It was moreover resolved, that another convention be called, to meet in the city of Albany, on the last Wednesday of January, 1823: that the standing committee be directed to make the arrangements for the same; that the Rev. Thomas Holliday be requested to deliver the sermon before said convention; and that the Rev. Elisha Yale, of Kingsborough, in the county of Montgomery, be appointed his substitute.—*Albany Daily Advertiser*.

BY T. G. FESSENDEN.

There is nothing better for a man than that he should eat and drink, and enjoy good in his labor.

Ecc. ii, 24.

With thankful heart to eat and drink,
Be happy while you can,
And reap the produce of your toil,
Is God's behest to man.

And he who thankfully enjoys
Each boon, which life affords,
With scant subsistence is more blest
Than misers with their hoards.

For only what we rightly use
Is really our own;
The rest is yielded to the winds,
Or left to heirs unknown.

Yet many a miser makes himself
A wretched guilty slave;
Although he cannot tell for whom
He toils and plays the knave.

Both soul and body he devotes
To Mammon and to care,
And gains alone the paltry post
Of steward to his heir.

To give some graceless wretch a chance
To dissipate his pelf,
He plots and labors till he brings
Damnation on himself.

With temperance then to eat and drink,
Be happy while you can;
Enjoy the produce of your toil,
Is Heaven's behest to man.

A man is always in a hurry to defend his weak side; and it is in some degree pleading guilty to be over hasty and solicitous in making a defence.

A man who is proud of his property will sometimes call himself poor that you may soothe his vanity by contradicting him. A great beauty, likewise, will pretend to believe that she makes an ordinary appearance, and

"In hopes of contradiction, oft will say,
"Methinks I look most dreadfully to day."

The most effectual way to satisfy such persons is to pretend to believe them, and to acknowledge that there is some truth in their assertions.

When pleasure is a man's chief object, disappointment and vexation are his principal acquisitions. Intervals of lassitude will occur, which inflict punishment more heavy than justice would impose on the vilest criminal.

Some men in pursuit of pleasure despatch the senses, which are the only inlets to the enjoyments they are in quest of. They roar bacchanalian songs till deaf, smoke till blind, and drink till they have almost as little sensation as the clods of the valley.

"In wild excess the vulgar breast takes fire,
"Till buried in debauch the bliss expire."

If a despot should order men to punish themselves in that way he would justly be deemed a most terrible tyrant.

Those who in confidence of superior capacities or attainments, disregard the common maxims of life, should remember that nothing can atone for the want of prudence; that negligence and irregularity, long continued, will make knowledge useless, wit ridiculous, and genius contemptible.

From the Albany Daily Advertiser.

Geological survey.—The geological and agricultural survey of the Erie Canal route, undertaken under the patronage of the Hon. Stephen Van Rensselaer, having excited considerable expectation, it may be gratifying to our readers to learn the following particulars:—

The geological outline, proposed to be taken this season, has been attempted with some success. But the heavy and long continued rains, prevented Professor Eaton, and his assistants from proceeding any farther than Rochester. So far they traced the connected series of rock formation with the primitive rocks of New England. Excepting that the rocks constituting the Little Falls, and the Great and Little Noses, present such abrupt protrusions of a primitive stratum into a secondary district, that these localities require renewed and very particular examination.

The examination of the route, through to Lake Erie, will be made with particular care, during the next season. We believe the result of this survey is to be published in two parts: the first part (in about a year) will contain the geological part, embracing all the interesting mineralogical localities; together with those rules for ascertaining the true indications of the useful minerals, which are deduced from the experience and observations of distinguished geologists and miners. The second part (to be published in about two years) will contain the agricultural part. It will embrace a digest of all the experience which can be collected from the best practical farmers of the west. Also, complete analyses of all the varieties of soil, with their particular requisites, defects and excellencies. The indigenous plants along the whole route, will be carefully analyzed, and their scientific, as well as common English names will be given; together with the general qualities of each.

A small pamphlet will soon be published, copies of which will be distributed along the route, giving particular directions to those who may feel disposed to lend their assistance in and of those practical sciences, which have a direct influence upon the well being of every individual in the community.

The remarkable exemption of the steam ship Robert Fulton from sickness, notwithstanding her frequent passage to and from New Orleans, Havana, and New York, is to be ascribed principally to the smoke, or the acid of smoke, called in chemical language the *pyroligneous acid*. The efficacy of smoke in destroying contagion has been tested on various occasions, particularly by Dr. Lind, who had a long and extensive experience on shipboard in tropical climates. The unusual healthiness of the crew of Capt. Cook, in the barque Endeavor, in her voyage round the world, may be brought as another instance of the salutary effect of smoke in the prevention of disease. During this voyage through various latitudes both of the frigid and torrid zone, out of a company of more than 120, and during a three years cruise, there were only four deaths, three of which were from accidents, and the other from consumption of the lungs. It was the frequent practice of Capt. Cook to kindle a fire in the well, at the bottom of the hold. In this way, the smoke penetrated every part of the hold of

the vessel, and the foul air being at this time rarified by the heat, was expelled in a great degree, and that which remained was purified by the action of the smoke, or the pyroligneous acid. Numerous instances might be adduced in illustration of this subject; but, as newspaper essays require to be short, what has been said may be sufficient. The writer, at some other time, will take occasion to show the efficacy of growing trees and vegetation of all kinds as preventive against summer and autumn disease, and will also point out the economy of nature in balancing the antidote to the bane of human life.—*Cahawba Press*.

That milk is often adulterated, or dilute with water, before it is delivered to customers we believe there is no doubt. Indeed, we have been well informed that there are persons who buy to sell again, and who sell at the same price for which they buy; relying for their profit upon the quantity of water which they can sell with it. It is an easy matter, however, for every consumer to ascertain whether he is imposed upon by adulterated milk: put a tumbler full in a situation exposed to the atmosphere; milk and water freeze at different temperatures they will therefore separate in the act of freezing, and the quantity of each can easily be ascertained.—*N. Y. Spectator*.

Bread.—The following important improvement in the composition of bread, the essential staff of life, deserves the attention of the community. It has lately been introduced into a respectable family in this city, and is pronounced superior to any other. Independent of a great saving, the bread is spongy, light and remarkably sweet.—1st. Take equal quantities of mealy potatoes and superfine flour.—2d. Peel and boil them, using the same water to make them in; which should be done as fine as flour.—3d. Add, (for three common loaves,) a tablespoonful of fine salt, and sufficient yeast.—4th. Mix the bread, and let it rise: bake it about one hour gradually.—*Albany paper*.

Sun Fish.—A fish of this rather uncommon species was caught, about a month ago, on the north of Shetland, and has been brought home by Captain Wilkinson, of the Greenland ship Mary Frances, of Hull. This fish, according to Dr. Shaw, is a native of the European seas, and from the singularity of its aspect, has long since attracted the particular observations of naturalists. Its general appearance rather represents the head of some large fish, than a complete animal, the body being short, and terminating abruptly on the hind part. Its skin is rough, and it is supposed to feed principally upon shell fish. During the night it exhibits a high degree of phosphoric splendor, from which, and its almost circular form, it has probably derived its name. The present specimen is about three feet four inches in length, and about two feet broad;—and its head bears no very distant resemblance to the countenance of an old man in a state of frightful distortion. This fish is sometimes observed to lie on its side, upon the surface of the water, and when taken it was in this situation. In the northern seas it is said to arrive to a vast size, and to have been found of 10 feet in length, and of the weight of 50 pounds.—*London paper*.

DISEASES OF CATTLE.

SELECTED AND COMPILED FROM THE BEST AUTHORS,
BY THE EDITOR.

Catarrh, or Cold; Epidemical Cold; Distemper.

Colds are very common, particularly in wet or cold weather; and though they are often thought of too little importance to require particular attention, yet, by neglecting them, and suffering the animal to continue exposed to the weather, the most serious consequences may ensue. From such neglect we often find that the animal decays in flesh and strength, becomes hide bound, and has a rough staring coat; at length tubercles form in the lungs, the mesenteric glands become enlarged, obstructing the passage by which nutriment is conveyed to the blood: this is succeeded by atrophy, consumption and death. It is highly important, therefore, to attend to this disorder as soon as it is discovered; and it is asserted that more good may be done by nursing, placing the animal in a warm situation, giving him warm, nourishing fluids, such as gruel, infusions of malt, &c. than from any medical prescriptions.

Colds are, at some seasons, so prevalent, as to be considered epidemic and infectious. On such occasions they generally occur with great violence, and are accompanied by fever, and, soon after the attack, by considerable debility.

On the first attack, the animal appears dull and languid; the eyes are watery, and, sometimes, partially closed; the appetite is diminished; and, most commonly, it is attended with cough. Swellings under or below the ears, difficulty in swallowing, and a discharge from the nostrils are not unusual symptoms of the complaint. When catarrh prevails to this degree, it is generally named *influenza*, or *distemper*, and has been thought contagious; but this opinion has not been proved to be true.

With respect to the treatment of this disease Dr. White observes that the hot stimulating drenches, commonly recommended, are decidedly improper. Bleeding at the commencement of colds is generally proper: the only circumstance which indicates its impropriety, is considerable weakness and low condition. The quantity of blood taken should seldom exceed two quarts. If the animal is costive, give a laxative drink; but if he purges or scours, give the following powder in gruel:

Powdered ginger	-	3 dr.
Antimonial powder	-	2 dr.
Camphor	-	1½ dr.
Tincture of opium	-	½ oz.

To be repeated after eight or ten hours, should it be necessary. If there be any difficulty in swallowing, and particularly if it be considerable, the following liniment should be rubbed about the throat:

Take of oil of turpentine and any common oil, of each	-	-	1 oz.
Liquid ammonia, commonly called spirit of sal ammoniac	-	-	½ oz.

Mix.

In common colds, however, says Dr. White, "I am inclined to believe that if the animal

were placed in a comfortable situation, and well attended to, medicine would be unnecessary. Even bleeding, in common slight colds, is seldom required; but should the animal, by a change of situation, become hot and feverish, should the eyes look red and the flanks move quickly, he should be bled freely; and if in any degree costive, the laxative [hereafter mentioned] should be given. When there are no feverish symptoms present the laxative should be mixed with some cordial medicine, such as an ounce of caraway seeds, and 3 or 4 drachms of ginger.

"When the influenza, or distemper, has not been attended to, or has been improperly treated at an early period, the animal becomes extremely weak, and every means must be employed to recruit his strength. On such occasions a tonic [such as the first mentioned prescription] may be given twice or three times a day, which in conjunction with a warm nourishing diet, and careful attendance, may ultimately effect a recovery.

If the animal should become costive, a mild laxative will be proper; about half a dose will be sufficient. If grass can be conveniently procured, when the animal is kept under cover a moderate quantity will be useful. In favorable weather, the field is the best place; but a sheltered and warm situation should be chosen.

LAXATIVE.

Sulphate of soda (glauher's salt)	1 lb.
Gruel - - - - -	1 qt.
Powdered caraway seeds	1 oz.

Mix, for one dose.

Whenever the disease appears to be epidemic, preventive means should be adopted, which is more particularly necessary when rain and cold winds prevail. Catarrh or cold is often an insidious complaint, and, if neglected, may produce very serious consequences.

Whenever caraway or any of the aromatic seeds are employed, they should not be purchased in powder, as they do not keep well in this form.

Mr. Lawrence observes that "The influenza or epidemic cold arises from frequent changes of the air, and the prevalence of north-east and easterly winds. As a great number, whether of men or animals, may be seized with this species of catarrh, at the same time and for the same cause, it has been supposed contagious, which indeed, may probably be the case in its inveterate and putrid state. This disorder is most prevalent in the spring, which succeeds a mild winter, when particular care should be taken that cattle are not exposed to currents of air from the north-east. I have known a whole fold-yard of oxen, horses and cows, dangerously affected in one night."

Mr. Lawrence advises "if the animal shivers with cold, and has cold breath, give a quart of warm ale,* in which is infused a table spoonful of grated ginger, two of spirit of hartshorn, and one of laudanum, repeating it in six hours, if the chilly symptoms continue, allowing warm water and a deep bed of straw. If feverish heat

* Beer or warm water would answer probably as well.

comes on, give nitre in warm water: when fever becomes predominant, bleed two quarts, unless the animal be a milch-cow, which never ought to be bled but in extreme necessity, and one ounce of cream of tartar, in three pints of warm gruel, sweetened with honey or treacle, [molasses.] On recovery of the heat, accustom it to the air by degrees, and notwithstanding having been nursed in the house, it will again become equally hardy as before."

Peripneumony, Pleurisy, or Inflammation of the Lungs.

This disease most commonly occurs to working cattle from over exertion, or from being suffered to drink largely of cold water, immediately after working hard, and when in a state of perspiration. Its symptoms are shivering; loss of appetite; an appearance of anxiety or depression; an increased motion of the flanks, or quickness of breathing; cough; opening the mouth; a discharge from the mouth and nose of a glutinous nature; the inside of the nose red; eyes dull; pulse hard; mouth harsh and dry; skin stiff; cold extremities; body full as if swelled with herbage; holds its head low and moves with difficulty; costive; on lifting the upper eye lid its under surface will be found unusually red, sometimes approaching to orange. If the disease happens to a milch cow, she soon loses her milk; and the ears, legs and horns are generally cold.

Dr. White says, "early bleeding is the grand specific in this complaint; but it must not be done sparingly. A cow or ox in tolerable condition, may lose from four to six quarts with advantage; and, if the symptoms do not abate in four or six hours, the operation should be repeated, to the extent of three or four quarts, unless the animal faint; whenever this occurs, on any occasion, the bleeding of course must be stopped. Faintness, however, when the disease is really inflammation of the lungs, is by no means an unfavorable effect of bleeding; it is proof that the operation has been carried to its full extent, and a recovery is most likely to happen. A large seton should be put in the dewlap, and moistened with oil of turpentine; and the sides should be well rubbed with the following embrocation:

Take of flower of mustard	4 oz.	
Oil of turpentine	-	2 oz.
Water of ammonia	-	2 oz.

The whole to be mixed with as much water as will bring it to the consistence of cream.

Immediately after bleeding, give the following drink:

Take of camphor	-	2 dr.
Nitre	-	1½ oz.
Powdered caraway seeds	-	1 oz.

To be given in a pint of gruel.

"Should the animal be costive, a clyster should be administered, consisting of about three or four quarts of warm water, and half a pound of common salt. A pint of castor oil, also, may be added to the above drink; if this cannot be procured, sweet oil, linseed oil, or even melted lard may be substituted.

"It is a bad plan to take only a small quantity of blood daily, or every other day as has been advised; for though it may sometimes retard the progress of inflammation, yet the animal will eventually be destroyed by it. Stimulating or heating medicines are highly pernicious.

"Inflammation of the lungs is a term, that has unfortunately been too often applied to diseases of a different kind; and it is from this error perhaps, that strong stimulating medicines have been recommended on such occasions.—There is an affection of the lungs and parts connected with them, which will not admit of the copious bleeding I have recommended; but the symptoms are widely different. There is not that difficulty and quickness in breathing; the pulse is weak, but not much quicker than usual; the kernels or glands, about the throat, are often swollen; sometimes there is considerable difficulty in swallowing, which is particularly seen when the animal attempts to drink: in short this is nothing more than a severe degree of catarrh or cold; but, even in this complaint, moderate bleeding is necessary, and powerful stimulants are extremely pernicious.—When the disease, however, has not been discovered for some days, and the animal appears much weakened by it, bleeding is of course improper." (TO BE CONTINUED.)

Massachusetts Agricultural Society.

The Committee on Agricultural Experiments submit for the consideration of the Board the following, in addition to their report dated the 10th day of October last, to wit:

That Col. Joseph Valentine, of Hopkinton, is entitled to the society's premium of \$30, for having raised the greatest quantity of Indian Corn, being 119 bushels and 26-32 of a bushel, on one acre of land. "The soil is a deep yellow loam—in 1821, the land was cultivated with Indian corn, and manured with ten cart loads of green barn manure, spread on the ground, and eight loads of compost manure put in the hills. In the spring of 1822, the ground was twice ploughed, and 20 cart loads of green barn manure spread on it—it was then furrowed in rows about three feet and a half apart; and about 20 cart loads of barn, hog and slaughter yard manure, were put in the rows; the last mentioned manure was mixed together, with one hoghead of Smithfield lime; the seed was the Brighton twelve rowed yellow corn, the kernels placed about 3 inches apart each way—the corn was hoed three times, all the suckers were pulled out in July; and in August all the suckers were again taken away, together with the false stalks, and those that were smutty; on the first of September the stalks were topped; and on the 26th the corn was harvested, and spread on a floor under the roof of a long shed, to give a good opportunity for drying it—there were 213 bushels of corn in the ear; one basket of which was shelled, and produced half a bushel and two quarts of shelled corn; so that had the whole been shelled on the day of harvesting it, the produce would have been 119 bushels and 26-32 of a bushel of shelled corn—on the 11th of Nov. the whole was shelled, and measured, and found to be 116 bushels and 28-32 of clear sound corn; the average weight of which was 58 to 59 lbs. the bushel—the entire expense of cultivating this acre of corn, including \$35, charged for 40 cart loads of manure, was \$44."

That Payson Williams, Esq. of Fitchburg, is entitled to the society's premium of \$30, for having raised the greatest quantity of Spring Wheat, being 23 bushels and 28-32 of a bushel, on one acre. "In the spring of 1822, as early as the frost would permit, the ground was ploughed, and harrowed; the seed, two and a half bushels of the Gilman wheat, sown; again harrowed, and ploughed in fine, with a horse plough, and left in this situation with the belief that the crop would endure our New England drought better, as the surface would be enlarged, thereby retaining more of the dews than a plane surface; the result, compared with neighboring fields, declares this belief not unfounded. As the field was seeded down with clover, herdsgrass, and red-top, this was also ploughed with the wheat; these plants not only stood the drought remarkably well, but at this time have completely covered the ground with the *Farmer's best carpet*. The quantity of grass-seed used by me, is never less than 12 lbs. of clover, and one peck of herdsgrass, to the acre. Here permit me to observe that innumerable are the instances in this country, where the farmer fails in his grass crops, by not allowing seed enough; and what is worse, the little he does give with such a sparing hand, is suffered to take its chance under that pest in agriculture called a bush harrow, which not only drags stones, and other loose matter, into heaps, but leaves the soil dead and heavy; and does not cover the seed deep enough to strive with our July drought effectually. It may be asked how the scythe is to follow the plough? to which I will answer, let the roller, an implement which every farmer would keep, did he consult his own interest merely, with a sufficient top or body to contain the larger stones, pass over the field lengthwise the furrow, in the dry part of the fall; this process will not only crush in the small ones, but even the surface for the scythe, without the least injury to the grass roots—to this digression I am impelled by no other motive, however much I may be mistaken, than the wish of advancing in some measure, the interests of my fellow citizens, whose good fortune it is to till the soil.—I had the wheat cut very early, when much of the straw was green, which, after laying about two days, was in excellent order for the flail; after which it was equal to swail hay for fodder—the amount of grain by measurement was 26 bushels and 18-32, from one acre and 18 rods—the quality of the grain is excellent, not one kernel of smut or burnt grain in the crop—the seed prepared by a thorough washing, after which it was immersed in thick white wash, made from good lime, so as to coat over every kernel—no fears need be entertained from the plentiful use of this liquor, as by way of experiment I have planted wheat after its lying in this liquor four days, which vegetated well." The committee are of opinion that the roller should be used immediately after the seed is ploughed in, in preference to the fall, as recommended by Mr. Williams. Said Payson Williams is also entitled to the premium of \$20, for having raised the greatest quantity of Potatoes, being 517 bushels, on one acre. "The land was twice ploughed, and furrowed three feet apart, and the manure, unfermented, made by sheep, and neat cattle, its quantity about 11 cords, placed in hills two feet apart, hands immediately following the cart with hoes to finish

the planting process, to prevent loss by evaporation—planting finished May 21—the kind of seed used, was the South American reds, 28 bushels to the acre, cut so as to allow two pieces to the hill—the weeding finished the 15th of June—the second and last hoeing the first of July, the vines beginning to bud, and were about eight inches in height; a few scattering weeds were occasionally pulled up, but no other disturbance was given to the vines till harvesting the crop, which was finished November the 3d; and by a careful measurement was found to be 517 bushels—the expense of cultivating the acre of wheat, including \$10 charged for the manure, was \$21,71—that of cultivating the acre of potatoes, including \$14 for manure, \$51."

That Mr. David Little, of Newbury, is entitled to the society's premium of \$20, for having raised the greatest quantity of Mangel Wurtzel, being 970 bushels, and one half of a bushel, on one acre. "The situation of said acre is as follows—a swell inclining south-westerly, of a rich yellow loam—in 1821, it was planted with beets, manured with about three cords of compost manure, and produced about 530 bushels. May 9th, 1822, ploughed, harrowed and furrowed three feet apart; four and a half cords of compost manure were put in the furrows and covered with a plough; then a harrow was drawn lengthwise the ridge to smooth the land, the seed was then sowed one row on each ridge, with four pounds of seed—half the quantity would I think be sufficient—June 10th, commenced ploughing between the rows, and weeding, and thinning at different times till July 16th—the plants stood 10 or 12 inches apart in the rows—the work was done principally by boys, estimating two boys to be equal to one man.—Oct. 31, Nov. 1st and 2d, they were harvested by men and boys, and produced 970 1-2 bushels of Mangel Wurtzel, besides 2 bushels of Carrots, and 109 Cabbages—three loads of the Mangel Wurtzel containing 137 bushels, were weighed at the town scales; the weight, according to the certificate annexed, was 3 tons, 2 c. 3 qs. 20 lbs.—Six swine mostly fed with the thinnings from the beginning of weeding, until about the first of October—there are trees on the said lot sufficient to produce 21 barrels of fruit—the entire expense of cultivating this acre of Mangel Wurtzel, including the cost of the manure and gathering the crop, was \$23 26 cents."

That Mr. Adams Knight, of Newbury, is entitled to the Society's premium of Twenty dollars, for having raised the greatest quantity of Onions, being six hundred and fifty-one bushels, on one acre. "The soil is a rich gravelly loam, with a gravel bottom; in 1821, it was cultivated with onions, and cabbages; and was manured with about five cords of barn manure, and produced a good crop—after the crop was off the ground, there were five cords of barn manure, and two and a half cords of leached ashes ploughed in—in April 1822, it was once ploughed, and sowed in rows 11 inches apart, which took between 3 and 4 pounds of seed—in the course of the season it was hoed between the rows and weeded four times—in September the onions were harvested, and there were 651 bushels—the entire expense of cultivating this acre of onions, including 21 dollars and 37 cents, the cost of manure, was 57 dollars and 38 cents."

That Messrs. Trisram and Henry Little, of Newbury, are entitled to the Society's premi-

um of Twenty dollars, for having raised the greatest quantity of common Turnips, being 637 bushels and a half on one acre. "The soil is a clay loam and had been down to grass 6 or 7 years—in 1821, cut about one ton of hay; it was then ploughed as deep as the sward would turn over; 10 cords of compost manure, the principal part of the compost was marsh mud, spread and well harrowed; it was ploughed in ridges three feet apart; about one pound of seed was sown with a machine on the ridges;—and a hand roller made to pass over them, which completed the sowing—when out of the way of the fly, they were thinned to the distance of one foot apart on the ridge—they were twice ploughed and harrowed; and harvested the last of October—the entire expense of cultivating this acre of Turnips, including 20 dollars for manure, was 35 dollars and 32 cents."

That Silas Little, Esq. of Newbury, is entitled to the Society's premium of Twenty dollars, for raising the greatest quantity of common Turnips, after another crop in the same season; having raised 615 bushels on one acre. "In the year 1821, something less than a quarter part of the acre was cultivated with Turnips, and about five common cart loads of compost manure, such as salt marsh pulverized, strong earth and sand was laid thereon; the produce was 30 bushels, the other three fourths had been laying to grass five or six years; and the present year we sowed Flax seed, where the turnips grew the last year; having spread on about the same quantity and quality of manure as before; we pulled the flax soon after the blossoms had fallen off, and there was a middling crop; the other part of the acre produced about 700 weight of hay, which was cut on the 26th of June; and the whole was ploughed and manured—the quantity put on the acre was 19 cart loads, of 40 bushels each—the quality of this manure was similar to that above described, but more sand in order to make the compost better, when mixed with our dark clay loam, with a clay bottom; nearly two thirds of this manure was spread on one half the ground, and after harrowing, was put into small ridges, with a small double mould board plough, two feet and nine inches apart; the other part of the manure was shovelled into furrows made with the plough, the same distance; the plough then passed between the furrows, covered the manure, and although so great a portion of the manure was spread on half the land, yet the other half produced about as much—the quantity of seed used was one pound and a half; the time of sowing was from the first to the tenth of July—the flax was pulled the 4th, and that part of the ground sowed the last; the whole was sown with a machine made for the purpose, and but one row on a ridge—when the turnips were up, and out of the way of flies, they were thinned with a hand hoe and fingers, at the distance of ten or twelve inches, and afterwards twice hoed and twice ploughed, with the small plough above mentioned—the time of harvesting, from the 28th of October to the 1st of November, and there was found to be 615 bushels, well trimmed and fit for market, and about five or six bushels of large defective rotten ones—we have weighed several bushels, and find a bushel will weigh 59 lbs.—the entire expense of cultivating this acre of turnips, including thirteen dollars for manure, was twenty-eight dollars and seventy-five cents."

That Mr. Asa Rice, Jr. of Shrewsbury, is entitled to the Society's premium of Twenty dollars, for the account of the best mode of rearing, feeding, and fattening Neat Cattle. Said Rice is also entitled to the premium of Twenty dollars, for proving by experiments, to the satisfaction of the Trustees, the utility and comparative value of the Cobs of Indian Corn, when used with or without the grain itself, ground, or broken. A paper on the subject of raising Indian Corn, two successive seasons, with the aid of Plaster Paris, on a high hill on the farm of Mr. Rice, which from its difficulty of approach, had until two years since been neglected, was also exhibited. These communications are too lengthy to be inserted in this report, but your Committee recommend that said papers, together with three very interesting communications from William Hull, Esq. of Newton, on the best mode of raising Indian Corn,—his mode of cultivating seven eighths of an acre, from which he procured 192 bushels of Corn in the ear, 4 bushels of dry Beans and several bushels of Turnips—and on the culture of Carrots, and Ruta Baga, be copied into the Society's Journal for January next.

Claims for premiums were also exhibited to your Committee by the following persons, for raising the greatest quantity of Indian Corn, on one acre of land, to wit: Mr. Asa Rice, Jr. of Shrewsbury, raised 53 bushels; Mr. Nathan Howe, Jr. also of Shrewsbury, 75 bushels; Mr. Daniel Mears, of Lynn, 87½ bushels; Messrs. Tristram and Henry Little, of Newbury, 116 bushels and 9 quarts; Payson Williams, Esq. of Fitchburg, 116 bushels and 12 quarts; and Mr. Daniel Burnham, of Newburyport, 117 bushels and 8 quarts. Mr. Jacob Wilkins, of Marblehead, raised 57 bushels of Barley, on one acre and ½ of an acre. "April 12, 1822, the land was ploughed about 8 inches deep, the soil loamy, inclining to gravel, descending to the North East from a ledgy knoll, which included a part of the premises; 13th, sowed three bushels of six rowed Barley, on what I considered the largest half of the piece—at the same time sowed one and a half bushels of two rowed Barley, on the remainder; sowed grass seed over the whole, and ploughed, and harrowed the same in. When the six rowed Barley was about six inches high, it was mowed down, and left on the ground; this was for experiment.—July 18, mowed the six rowed Barley, and put it into the barn. 21th, mowed, and put into the barn, the two rowed Barley. The six rowed Barley appeared to be about 12 days forward of the two rowed in ripening—both were stacked separately in the barn; and each quality thrashed and kept separate. August 30th, the Barley being cleansed, was measured—the six rowed measured 34 bushels; and the two rowed measured 23 bushels—the straw we consider in value to be equal to the labor." No premium was offered for raising the greatest quantity of Barley; but your committee are induced to recommend that the Treasurer be authorized to pay said Jacob Wilkins, the sum of Twenty dollars.

For raising the greatest quantity of common Beets, Parsnips, Ruta Baga, Cabbages, and dry Peas—for introducing any Grass not before cultivated in this Commonwealth, and proving by actual experiment, and produce satisfactory evidence of its superiority in any one quality, to

any now cultivated—for the most satisfactory evidence on "Soiling Cattle," not less than six in number, and through the whole season, together with a particular account of the food given, and how cultivated—for making the experiment of turning in green crops as a manure, on a tract not less than an acre, and prove its utility and cheapness, giving a particular account of the process and its results—for proving by actual experiment, the best season and mode of laying down land to grass, whether Spring, Summer or Fall seeding be preferable, and with or without grain or different soils—for raising the greatest quantity of Vegetables, Grain, Peas and Beans excepted, for winter consumption of the stock on his own farm, and not for sale, in proportion to the size of the farm and stock kept, having regard to the respective value of said Vegetables as food, stating the expense of raising the same, and the best mode of preserving the same through the winter—for taking up in one season, on his farm, the greatest quantity of good Honey, and shall at the same time exhibit superior skill in the management of Bees—for giving proof of having produced the largest quantity of dressed Flax raised on one acre—no claims for premiums have been exhibited.

The Board will perceive by the papers accompanying this report, that of the seven claimants for the premium for raising the greatest quantity of Indian Corn on one acre, the quantity produced by four of the competitors was very nearly the same. Your Committee in awarding the premium to Colonel Valentine, were induced to decide in his favor as well from the quantity of sound corn, as from the weight of the grain; it will be seen that Mr. Burnham's Council Bluff Corn, weighed only fifty pounds; that of Col. Valentine, fifty eight to fifty nine pounds the bushel.

For the Committee,
THOMAS L. WINTHROP, *Chairman*.

Boston, Dec. 23, 1822.

From the Northampton Gazette.

MR. EDITOR—In some places I have known a very simple expedient made use of for the security of Churches against fire, when neighboring buildings are burning. This is, the providing two or three barrels of brine, and placing them in some convenient part of the steeple.—If at any time the fire should endanger the church, a few men, with buckets, posted at the barrels, might be of great use. Brine possesses many advantages over water, for such a purpose. It may be kept through the winter without freezing—through the summer without becoming brackish or offensive; and is, as is well known, much more efficacious in quenching fire. The expense can certainly be no objection.

PENNY WISE.

French chesnuts.—At a meeting of the Philadelphia agricultural society, Nov. 19th, specimens of large French chesnuts were shown, which grew near Wilmington, (Del.) The tree was planted in 1806, and first bore fruit in 1816. The nuts came from France. In 1820 one nut was selected from a burr containing two others, which weighed more than 20 pennyweights. In Spain, Italy, and the south part of France, these chesnuts are said to constitute the principal part of the food of the peasantry.—*Ibid.*

Extracts from an Address delivered before the Worcester County Agricultural Society; by Hon. LEVI LINCOLN.

"The necessity of labor is interwoven with the condition of man; and its results are made inseparable from his very existence. Yet amidst the artificial arrangements of society, in which individual situation is so widely varied, and the immediate supports of life so differently derived, men do indeed appear to have lost sight of the first sources of subsistence, and to regard with indifference, or as of subordinate concern, the only means by which, under Providence, their lives are upheld. While enjoying the *wealth* which Commerce bestows, and the *honors* which Learning and Professional Eminence confer, the *Art of Husbandry*, and the humble employments of Manual Labor, are regarded but as of little moment. It is hardly considered that even *Commerce* consists in an exchange of the productions of the soil, and that the cultivation of the ground has preceded, in all ages, that state of civilization upon which Learning and all the distinctions of society are founded. The necessity, value, and the virtue of labor upon earth, are as certain as all earthly objects are important. Whoever doubts of this, need look no further for conviction than to the *savage* state, where man, for *food*, eats man—where letters and the arts are unpractised and unknown—and where, in the instinct of nature only, man lives a rude, fierce *animal*, and dies unconscious of intellectual and immortal being. To vindicate the arts of Husbandry, and the pursuits of Agriculture, can therefore neither be necessary, nor becoming the age in which we live. If civilization be a blessing, then is the agricultural state, which can alone uphold it, a primary good;—if the capacity of mind and the powers of intelligence constitute the superiority of human nature, their *exercise* will furnish to every man the highest assurance of the sources of their cultivation, and of the means, the scope, and the end of their improvement."

"While, in many of the most fertile parts of our country, the *grower* of the produce is either unable to make sales, or must receive the avails reduced by the charges of tedious and expensive transportation, and the commissions of consignees, agents and factors—a direct and ready disposition of the surplus of our farms, most generally, may be made at the very door of the farmer, or, at *his election*, may be carried, by his own domestic means of conveyance, at a profitable advance, to a sure, quick and not far distant market in the capital of the State. Strange, that so obvious an advantage should not be more highly appreciated! Of what avail is it that the boasted land of the *West* will produce its *hundred-fold* to labor, in comparison with the stubborn soil of our home, if the use for the product be limited by the consumption of the grower? Is it that there is a deficiency of that whereon to live, that the spirit of emigration has gone forth, to redeem the wilderness from the savage, and to reduce the waste to cultivation? What, though the hills are covered with verdure, and the vallies are filled with corn—if the value be in the inverse ratio with the plenty, how does the abundance advance the interest of the cultivator? Wherefore is it of consideration with him, that his garners should overflow, if the price be low, or there be no purchaser for the commodity? Be it, that he is

spared the hard labor of tillage, is there not a counterpoise in the privations of solitude, and in the loss of the aids, and comforts, and improvements of society? Ask the returning Emigrant from the *West* or the *South*, which *now* he most highly appreciates—the rough and hard, but vigorous soil of the *East*, with the necessity of labor to subdue and improve it, and the conveniences and pleasures of social intercourse for his recompense—or extent of territory, useless fertility and idleness, in a situation where neighborhood is unknown, the means for the education of children are denied, and opportunities for moral instruction and the public worship of God unenjoyed? Again: address yourself to his calculations of interest, and demand of him, upon his *practical experience*, in which is most profit, the smaller quantities of grain, at their greater value *here*, or the greater abundance at the diminished prices *there*?—his *one* bushel of corn, worth one dollar, raised for the home market *here*, or his *six* bushels to one, worth twelve and a half cents per bushel, grown for exportation *there*? Nor let your inquiries be thus easily satisfied. Hear from him the sufferings to which first settlers are exposed, of the terrors of the war-hoop, and of the wild beasts' howl—learn the new and painful diseases which an unused climate generates, and for which, with "the thousand ills which flesh is heir to," there is no helping, healing aid at hand. Then, when thus prepared for just comparison, turn to your own situation, and say, why have you not all which in human condition should make satisfied? Why leave the land of your nativity, and of generous reward to your exertions, rather than enrich it by your industry, and endear it by your labors?"

"*Habit and prejudice* are powerful opponents to improvement, and they are in a great measure incident to the business of Agriculture. The cultivation of the earth, is a *practical* lesson, taught to the Husbandman in earliest life. He is instructed in the ways of his father, and the *mode* which experience has approved as safe, will be reluctantly yielded to the mere promise of experiment. Hence, from generation to generation, men pass on in the track of their predecessors; believing that the path which is explored, is in the only direction to their object, and that those who deviate, wander to their destruction. To conquer this stubborn habit of reflection is the greatest effort and best result of Agricultural Associations. In vain may the *tongue* and the *pen* be employed to satisfy the practical man of the errors, which a life of labor has confirmed, and the experience of ages has consecrated. He is either deaf, and blind, and dumb to your appeals, or answers you in the language of distrust, and with the reproach that they are theories of idle speculation only. But make for him the experiment, explain to him the method, exhibit to his natural senses the successful result—he will hesitatingly yield credit to ocular demonstration, and tardily follow in the footsteps of improvement."

"Of the same pernicious tendency with confirmed habits in the *mode* of husbandry, is prejudice for *form, size, or color*, over useful properties, in domestic animals. Forgetting the trite saying, "that handsome is which handsome does," (the Ladies will pardon me—this vulgar adage is applicable only to brutes.) farmers

are too prone to consult *fancy* rather than *judgment*, and to prefer the beautiful, though indifferent in quality, to the more valuable of ordinary appearance. This bad taste is to be overcome by a sense of *interest*. When it shall be known that the *form* we least esteem may be best adapted to labor or fatten—that the *color* we most dislike is the characteristic of a breed by far the most productive to the dairy, the standard of excellence will become that of profit—and the kind which is best fitted to our particular object will be the first sought for attainment. The enlightened Agriculturalists of Europe, with the nicest care, select their breeds for the peculiar qualities they desire; and so distinctly preserved are they to the use for which they are obtained, that the characteristic husbandry suited to soil and situation in different districts, can be readily determined by a passing observation of their cattle only. In this respect, we are vastly behind the Farmers of England. While good animals of the ordinary race are common and cheap with them as with us, the immense prices which they willingly pay for the more rare and valuable breeds bear strong proof of their superior discernment, or better spirit of improvement. Happily here, also, correct opinions are becoming influential, and that *prejudice*, or *false economy*, which has hitherto excluded from our possession the finest stock of Europe, is yielding to a generous enterprize in its introduction, and to a liberal encouragement of the best means of improving our own race of valuable animals."

"One other most obvious impediment to our agricultural advancement, is of so general endurance, yet so easy of corrective, that I must solicit your patience, while I briefly notice it. The use of implements of husbandry of imperfect construction, or in bad condition, it is confidently believed, is a greater annual tax to the yeomanry of the country, than all the assessments imposed by law. The hindrance to labor *in time*, the greater hardship of its accomplishment, and its less effectual operation, by the "togg'd chain," the "rack'd cart," the "dull plough," the "toothless harrow," the broken *hoe*, and *spade*, and *rake*, and *fork*, if kept in accurate account by each individual, would present an aggregate of loss reproachful to many, and criminal even to the most careless. Good instruments in the business of husbandry, are no less important than in the mechanic arts; and to Farmers I appeal, what mechanic would they give employment in the use of tools out of order? or, what compensation would they make him for time spent to repair them? The great advance in agricultural skill, within the few last years of spirited enterprize, has been attended with corresponding improvements in implements to facilitate labor; and it is as decidedly for the interest as it is for the comfort of the husbandman, to possess those of the most thorough and approved models."

From the Metropolitan.

PLANTING OF STONE FRUIT.

On this subject, one pertinent fact faithfully related, is worth forty curious conjectures, and the following is such an one. On the 28th day of November, 1775, I removed a cherry-tree, the body of which was thicker than the calf of my leg, and on the 19th of June next following, gathered six pounds of very fine cherries from

that is six months and fourteen days from planting of the tree. Now, if this be an extraordinary fact, may we not set down the 28th of November as the best day in the year for planting cherry-trees? The hole in which this was planted, was dugged about eight inches deep; and a stake firmly fixed near the middle of it. The tree was then bound to the stake, so that the roots were four inches shallower than they stood where the tree grew originally.—The earth was then thrown into the hole until it was level with the surface of the ground and immediately plentifully watered so as to carry the earth among the roots: and then while the surface was yet wet, about eight inches more earth was added, which consequently covered the body of the tree so much deeper than it grew, yet leaving the roots not so deep as they grew. Conjecture may be allowed to say, that the season vegetation had entirely ceased, and the buds for next year's growth were perfectly formed, and ready to grow with the first appearance of the spring. Young peach-trees, moved but a small distance, at the time their blossoms are just beginning to open, will sometimes ripen their fruit the same fall; but their growth in the next year, will not be so vigorous as of those planted between the middle and end of November, or those planted early in the spring. The essential points in planting of fruit-trees, are, that they be planted rather shallower than they originally grew—that they are firmly and steady in their places, and that the water run from them both in the winter and the spring, rather than toward them. There is one observation in an old almanac, perhaps seventy or thirty years old, that is well worth remembering, because it is true, that "a free use of fine ripe fruit in this country, would on an average, add seven years to the life of each citizen, in addition to the advantages of sound health, and the indulgence of the highest luxury the world ever did or can afford." T. G.

FACTS AND OBSERVATIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY. FOR THE NEW ENGLAND FARMER.

VETERINARY COLLEGES—CATTLE-MEDICINE, &c.
An English writer says "The establishment of a veterinary college has had the very useful effect of turning the attention of a far greater number than formerly, of medical men, to veterinary pursuits and inquiries, and, in a great measure, to wipe away that false sense of shame, which many gentlemen of the faculty entertained at the idea of becoming horse and cow-doctors; a most groundless prejudice in any view, particularly when it is considered, that men of the first rank and fortune in the country, think no degradation, but a useful and patriotic employment, to obtain personal and practical skill in the management of live stock.

"The faculty of cattle-doctors, I shall hope, may be considerably improved by the addition and presence among them, of a number of regular professional men, in various parts of the country; indeed whatever turn improvement may take, the former must be generally dependent upon for a length of time. And in remote and secluded parts of the country, where even the lowest practitioners are not to be found, it inevitably results that the proprietor, or his servants, must fill the office of doctor to the locks and herds.

"Let the proprietors of cattle renounce, forever, the insane folly of offering premiums for specifics to cure incurable diseases! and the hope of providing medicines, which, by a miraculous operation, will enable men to continue in the habit of exposing their animals to the constant risk of such diseases: for example, sheep in those situations, which nature has decreed shall forever rot them. Prevention of disease is alone a grand improvement of the breed. It is a great profit; for in case of general disease in a flock or herd, we are not only to reckon the loss of those individuals which die, with the doctor's bill, and our own servants' time and attendance, but the loss of time and thrift in the survivors, sometimes the heaviest loss.

"Upon every farm, it is truly necessary to the well being of the cattle maintained, that there be houses or sheds, sheltered yards, and spare inclosures, for the comfortable reception of the diseased. The want of such conveniences, or an indolent prejudice against the use of them, is in itself a real malady, and one great cause why slight affections grow into incurable diseases. The proper instruments of administration or operation, should also be provided, and always ready for use; and where much cattle is kept, it would be of considerable benefit to set apart a piece of garden ground for the production of medicinal herbs, for though botanical simples are justly rated by modern practice far below their ancient character, yet infusions or decoctions of them, are excellent vehicles in cattle medicine for articles of superior efficacy, and, in fact, as I have often experienced, some of them possess, in a considerable degree, the virtues attributed to them."

Another writer observes—"It is well known, that uneducated farmers are fond of mystery in medical matters; and this very naturally, as they have always been led to believe that, for every disease, there is an infallible remedy, termed a receipt; and the more numerous the ingredients are in that receipt, the higher opinion have they of its efficacy. Upon this principle, perhaps it is, that the cow-doctor, or cow-leech as he is commonly termed, generally obtains their confidence; while the veterinarian, who adopts a more simple mode of treatment, relying wholly, perhaps, upon bleeding and a proper regulation of diet, does not appear to them sufficiently skilful; and any attempt he may make to explain the nature of the disease, or the principle upon which he acts, would be quite unintelligible. With respect to the qualifications of those cow-doctors, it is unnecessary to say much, in the operative part of the art, they are useful in a certain degree."

ARRANGEMENT OF AGRICULTURAL LABOR, AND DOMESTIC MANAGEMENT.

"At the foundation of a proper arrangement, it is necessary to have a plan of the farm, or at least a list of the fields or parcels of land into which it is divided, describing their productive extent, the soil, the preceding crops, the cultivation given to each, and the species and quantity of manure they have, severally, received. The future treatment of each field, for a succession of years, may then be resolved on with more probability of success.

"With the assistance of such a list, every autumn, an arrangement of crops for the ensuing

year, ought to be made out; classing the fields or pieces, according to the purposes for which they are respectively intended. The quantity of each crop, whether arable or meadow [plough land or mowing] as well as the extent of ground intended for pasture, will thus be ascertained. It will not then be difficult to anticipate what number of horses [or oxen] and laborers will be required during the season; nor the stock that will be necessary for the intended quantity of pasture land. The works of summer and harvest will be foreseen, and proper hands engaged in due time to perform them."

As nothing contributes more to facility and satisfaction in business, than to prepare for what must be done, a farmer should arrange his plans regarding his crops, for three or four years; regarding team labor, when frost and bad weather do not intervene, for as many months; and regarding hand labor for as many weeks, according to the season of the year.—A general memorandum list of business to be done, is therefore essential, that nothing may escape the memory, and that the most requisite work may be brought forward first, if suitable to the state of the weather. In this way, the labor will go on regularly, and without confusion, and a proper attention and force may be applied to every part of the farm.

The following rules, connected with the arrangement, and the successful management of a farm are particularly to be recommended.

1. "The farmer ought to rise early, to see that others do so, and that both his example be followed and his orders obeyed. In the winter season breakfast should be taken by candle light, by this means an hour is gained, which many farmers lose by indolence: though six hours in a week are nearly equal to the working part of a winter day. This is a material object where a number of servants are employed.

2. "The whole farm should be regularly inspected, and not only every field examined, but every beast seen, at least once a day. On a large farm, the whole day may be well employed in such essential duties.

3. "In a considerable farm it is of the utmost consequence to have the servants specially appropriated for each of the most important departments of labor; for there is often a great loss of time, where persons are frequently changing their employments. Besides, when the division of labor is introduced, work is executed not only more expeditiously, but also much better, in consequence of the same hands being constantly employed in one particular department. For that purpose, the ploughmen ought never to be employed in manual labor, but regularly kept at work with their horses [or oxen,] when the weather will admit of it.

4. "To arrange the operation of ploughing according to the soils cultivated, is an object of essential importance. On many farms their are fields, which are brought to a situation unfit to be ploughed, either by much rain or by severe drought. In such cases, the prudent farmer, before the wet season commences, will plough such land as is in the greatest danger of being injured by too much wet; and before the dry period of the year sets in, such land as is in the greatest danger of being rendered unfit for ploughing by too much drought. On farms where these rules are attended to there is no

ways some land in a proper condition to be ploughed; and there is never any necessity, either for delaying the work, or performing it improperly.

5. "Every means should be thought of, to diminish labor, or to increase its power. For instance, by proper arrangement, five horses may do as much labor as six perform, according to the usual mode of employing them. One horse may be employed in carting turnips during winter, or in other necessary farm work at other seasons, without the necessity of reducing the number of ploughs. In a hurried season, when driving dung from the farm yard, three carts may be used, one always filling in the yard, another going to the field, and a third returning; the leading horse of the empty cart ought then to be unyoked, and put to the full one. In the same manner, while one pair of horses are drilling for turnips, the other three horses may be employed in putting the dung upon the land, either with two or three carts, as the situation of the ground shall require. By extending the same management to other farm operations, a considerable saving of labor might be effected.

6. "A farmer ought never to engage in a work, whether of ordinary practice, or of intended improvement, except after the most careful inquiries; but when begun he ought to proceed in it with much attention and perseverance, until he has given it a fair trial.

7. "It is a main object in management, not to attempt too much, and never to begin a work, without a probability of being able to finish it in due season.

8. "Every farmer should have a book, for inserting all those useful hints, which are so frequently occurring in conversation, in books, or in the practical management of a farm. Loose pieces of paper are apt to be mislaid or lost, and when a man wishes to avail himself of them, for examining a subject previously investigated and discussed, he loses more time in searching for the memorandum, than would be sufficient for making half a dozen new ones. But if such matters are entered into a book, and if that book has an index, he can always find what he wants, and his knowledge will be in a progressive state of improvement, as he will thus be enabled to derive advantage from his former ideas and experience.

"By the adoption of these rules, every farmer will be master of his time, so that every thing required to be done, will be performed at the proper moment; and not delayed till the season and opportunity have been lost. The impediments arising from bad weather, sick servants, or the occasional and necessary absence of the master, will in that case, be of little consequence, nor embarrass the operations to be carried on; and the occupier will not be prevented from attending to even the smallest concerns connected with his business, on the aggregate of which his prosperity depends.

"Besides, an arrangement for carrying on operations without, a settled plan for the management of the family within, ought not to be neglected. In regard to house-keeping, the safest plan is not to suffer it to exceed a certain sum weekly, stating the value of every article from the farm. An annual sum should be allotted for dress, and the personal expenses of the farmer, his wife and children, which ought not to be exceeded. The whole allotted expense

should be considerably within the probable receipts; and at least one-eighth of the income actually received, should be laid up for contingencies, or expended in extra improvements on the farm, if it belongs to the farmer in property, or is held for a term of years."

TO THE EDITOR OF THE NEW ENGLAND FARMER.

I desire through the medium of thy useful paper, the advice and direction of some experienced gentlemen of the Eastern States whether there is not a better mode of boiling the sap of the sugar maple than in iron kettles over a fire? I am led to these inquiries by the circumstance of a young man, lately from an eastern State, having erected in this neighborhood a wooden distillery that is boiled by steam conveyed into the bottom of the cistern by wooden pipes from a small iron kettle, set in an arch some thirty feet distant.

Having had upwards of thirty years experience and observations in manufacturing maple sugar in the same orchard, I had thoughts of publishing some directions for public benefit, and wish to know if there hath been any late improvements in boiling down the sap by steam.

SAMUEL PRESTON.

Stockport, Pa. Dec. 23, 1822.

THE FARMER.

BOSTON:—SATURDAY, JAN. 4, 1823.

After tendering the compliments of the season to our patrons, subscribers and well-wishers, we shall presume on the privilege, which custom sanctions, on similar occasions, to make a few observations on such events of the past year as will probably stand the most prominent in the annals of the times. Our retrospect, however, will consist merely of a few transient glances, not of a regular survey. We do not profess to be so voluminous a chronicler of weekly novelties as most of our brethren, whose papers are not, like ours, devoted to some specific purpose. A less minute recapitulation of recent incidents will be expected from us, than from those wholesale dealers in diurnal occurrences, who print daily papers; or even from the conductors of those weekly vehicles of all sorts of intelligence, whose columns are almost exclusively occupied by such marvellous matters of fact as are technically called *news*.

The year past has not been signalized with any transactions or productions which can make much display in the records of ages. Some nations are struggling for liberty, some looking on with apathy, and others apparently with interest; and if their good wishes were as prevalent as those of Fortunatus, would be sure to break the yoke of the oppressor, and set the captive free. The Greeks are maintaining an unequal and sanguinary warfare with a ferocious foe. The U. States assist them with newspaper expressions of sympathy, sentimental toasts, and town-meeting resolutions. These, should they ever reach the ears of the belligerents, may encourage the hearts, if not strengthen the hands of the descendants of Leonidas. Great Britain, who might be the emancipator of Greece, has hitherto evinced a degree of coolness towards her cause which seems hardly compatible with that regard for the welfare of Christendom which is due from a nation whose kings have ever borne the title of "Defender of the Faith." The Emperor of Russia, although at the head of the Greek Church, appears to care but little about the Greek nation. It is possible, however, that those powers are actuated altogether by that pacific policy, which has of late, (at least ostensibly) been the

order of the day in Europe; and it may be that Congress at Verona will yet take measures to aid cause of men, whose unassisted efforts and suffer reflect disgrace on civilized mankind.

The Spaniards do not appear to know very well how to manage the little liberty which they have acquired. The king and constitution (to use a farmer's phrase) work as awkwardly together as a couple of off-oxen. The king is at the head of the constitutional, alias publican party, and the rebels are royalists, who rally against the king round his own standard, and under his own banner! They oppose the king in the name of the people, and in behalf of his majesty, and would, probably shoot or behead him for his own benefit, if that was the law of the land. Whether the elemental political contention will subside without settling in the calm of despotism, is a problem which time can resolve.

France seems settled on her legs. Political violence has occasionally been manifested by frolics in her legislative bodies. But nothing more formidable than bubbles and fumes has originated from the boiling of the political caldron; although it often seemed on the point of exploding like the boiler of a high temperature steam engine. We are apprehensive that the French nation would not make the best possible use of freedom if they had it in possession, and their apprenticeship to liberty under Bonaparte does not appear to have taught them how to be their own masters.

England of late has presented nothing novel or extraordinary, except the travels of Majesty; the loyalty of his Scotch subjects; the decease of Lord Castlereagh; the liberation of Hunt, the main spring of radical movements; and the accession of Mr. Canning to the office of Prime Minister. This last event it is thought is inauspicious to the cause of freedom in Spain; and is hoped that the Greeks have at least nothing to learn from his counsels. The season in England has been uncommonly productive, and Wheat so low that considerable quantities have been shipped to advantage to New York.

South America still remains a theatre of contentions. Freedom is a plant which does not appear to find congenial soil in that part of the torrid zone. There can be no doubt but Spain has lost the sceptre of dominion in S. America. But whether the South Americans will succeed in establishing free and stable governments on correct republican principles is somewhat problematical.

With regard to our own "happy land," we have every blessing bestowed which can lead us to be grateful to the Source of all benefits. Notwithstanding some unfavorable appearances, in consequence of early drought, the fruits of the earth were, perhaps, never more abundant. The rancor of political animosities seems to be nearly annihilated. The mists of party can now neither magnify nor conceal the merits or demerits of candidates for office, and he who deserves best of his country, in general way, has the fairest prospect of succeeding to its honors and emoluments.

After these brief sketches of "things in general" this passing peep at the great Babel, called The World, we hope to be indulged in a word or two relating to our own concerns. It is now about five months since we commenced the publication of the New England Farmer. Our subscribers are not so many as we wished, nor so few as we have feared. We have had less assistance from correspondents than our hopes had led us to anticipate; but we have received some valuable communications, and take it for granted that there are others in the germ, which will, in due season, be developed.

should not only be gratified, but the public good be promoted as well as individuals benefited, a larger proportion of our cultivators would subscribe for the *New England Farmer*. This we can evident by a very little reasoning on the subject, well observed by Lord Bacon that "knowledge is *cash* to a farmer—money in hand, and *at interest*. It teaches how to work to the best advantage; and he who "works it right," is on the way to fortune. The *New England Farmer* is a story of that kind of knowledge which is wealth to the husbandman. We say nothing of our own writings and at present will not boast of any communications which we have received or may receive from our intelligent correspondents. But the extracts and abridgments from the works of Sir John Smeaton, Sir Humphrey Davy, the various Dictionaries, works upon Farmery, Transactions of the different Agricultural Societies, both foreign and domestic, quotations from the *American Farmer* and the *High Boy*, and various other agricultural books and papers, cannot fail to prove profitable to every farmer who can think as well as read, and has judgment enough to make a proper use of the knowledge which is placed before him.

UNPLANTED SCIENCE AND ENGRAFTED LITERATURE.

Many of our brethren of the type and quill, who regard those learned hebdomadal publications, cyclopedias, Intelligencers, *Heralds*, *Messengers*, *Patriot*, *Pazettes*, *Journals*, &c. &c. &c. have, of late, been assiduous in decorating their literary parterres, with potatoe patches, and scientific pumpkin-yards, articles taken from the nursery and seed plot of the *New England Farmer*. Although we are not only willing, but truly solicitous that the public should reap an abundant harvest from our humble layet it would be no more than common civility (to say nothing about common honesty) would seem to require, for our co-adjutors to just intimate the source whence they generally derive their agricultural treasures. But, instead of this, many of the gentlemen whom we allude to, have, since we began our establishment, opened petty offices in one corner of their papers, for the disposal of agricultural and economical intelligence, and taken almost their whole income in trade (save their brass) from our premises, not without licence, but without acknowledgment! of these Georgical geniuses, by thus engrafting unscientific on their own stumps, contrive to pass for scientific agriculturists, when in fact they hardly know a pumpkin from a hoe, or a hay-cart from a horse, are, however, perfectly welcome to any or all our articles, provided they will be so good as to prefix to them the words *New England Farmer* to such of our words and chattels as they may from time to time consent to exhibit in their columns. Indeed, the more publicity they give to our productions, with the above-mentioned condition, the better we shall be served, and, perhaps, the more their readers will be benefited.

We do not intend to say any thing against gentlemen who are taking the liberty to select our selections, without intimating the source from whence they derived them. True it is that we have toiled through the mass of matter of foreign journals, cyclopedias, and other repositories of science, and employed ourselves in collating, condensing and compacting such passages as we thought might be proper for our publication, and made it official to the public, till our very spectacles waxed dim with fatigue, and our brains seemed in danger of

becoming dry as an anatomical preparation. True it is that after we have impressed on our columns these fruits of our researches, with a faint hope that somebody might appreciate our exertions, the same matter has been shortly after presented to us in some country paper, with every common indication of its being the result of the sapience of the Solomon who conducts it! These things, however, as we said before, we shall say nothing about. But when we have written an article which is as original as any thing can be, if composed of the letters of the alphabet, (which we do not pretend to have invented) with a great deal of that kind of toil which exhausts the mind without invigorating the body, and attenuates the thread of life till little or nothing is left for the destinies to snap with their scissors—when we have done this, to have the fruits of our labor come staring at us in a village paper as the production of some journalist, who

"Pretends to be a sage philosopher,

But never read Alexander Ross over;"

and who, by the courtesy of the public, and the indulgence of a free government, is suffered to soil white paper and blacken every thing about him with printer's ink;—this might "in Job or Griswold stir mood," and provoke to active indignation any one not as tame as an over-worked ox that lies down in the furrow.

FARMER SUMMARY OF NEWS.

CONGRESSIONAL.

Nothing of great general consequence appears to be on the carpet in our National Legislature. A motion for fortifying Thompson's Island, off Florida, has been adopted. Mr. Wright has offered a resolution for an inquiry into the expediency of arming all the militia with rifles, excepting those residing in cities, towns and villages. A bill has been before the House, and is committed, for incorporating an U. S. Naval Fraternal Association. A memorial of William Thornton and 137 other citizens of the District of Columbia, has been presented by Mr. Dwight, praying Congress to appropriate two or three millions, in provisions, or whatever may be necessary to the Greeks; which has been ordered to lie on the table. Bills have passed the House to regulate the collecting of duties on goods imported from Canada, and for making perpetual the laws for the punishment of piracy.

THE MASSACHUSETTS LEGISLATURE.

Assembled on the 1st inst. and immediately proceeded to business. The Governor's Message was received at 12 o'clock, and is an official document of too much merit for us to attempt to abridge or analyze it. The last paragraph announces the determination of His Excellency to decline being considered a candidate for re-election to the office of chief magistrate.

A late arrival at New York has brought London dates to the 6th of November. They contain a report that a battle has been fought on the frontiers of Spain in which the royalists had proved victorious, and the Constitutional Brigadier-General Torrigio, was mortally wounded. Letters from Paris, however, pronounce the foregoing to be mere rumours.

The Congress of Verona were sitting, without having hatched any thing of consequence.

Paris papers assert that Greek deputies were on the way to Verona, and that Alexander, and all his ministers were decidedly in favor of a war with Turkey; but are opposed by other powers.

The late account of Morales having gained a victory over the Colombian army is incorrect. On the contrary, Capt. Mason, lately arrived at Baltimore, gives information of two battles having been fought on the 22d and 24th of November, in which the Colombian forces proved victorious. The royal troops, in consequence, were obliged to evacuate Maracaibo on the 26th, and that place was taken possession of the same day by Gen. Montilla.

A system of outrage appears to be the order of the day in Ireland. An Irish paper states, that "the infuriated and desperate peasantry are again collecting

arms; and again have the gentry who were not able to remove to towns or to the capital, called upon the Government for assistance. But what can the government do more than it has done?"

We learn from the *National Intelligencer*, that Commodore Porter arrived at Baltimore on the evening of the 24th inst. and almost before he was known to have been in the city, bought, and sent off to Norfolk, under the command of Lieut. Newell, a whole squadron of eight vessels, intended for service against the pirates. The Commodore has proceeded to the North, to procure a steam-boat to form part of the expedition.

The *National Intelligencer* informs that Mr. Rich, Consul of the United States at Valencia, has obtained possession of the original manuscript of Columbus' account of his first voyage to America. Mr. Rich resides not far from the port from which the illustrious navigator took his departure, on his first voyage of discovery. The manuscript, it is said, will be translated and published in the Spanish and English languages, and the original deposited in the capitol of the United States, at Washington.

Precepts have been issued, appointing the first Monday of March, for the second trial to elect Representatives to Congress, in the two Worcester Districts, and Essex South District.

A philanthropic quaker, whose name is Allen, is at Verona, urging the cause of the enslaved Africans. He regularly appears before the sovereigns with his hat on, and they regularly admit him in the character of a privileged friend.

The Grand Jury of the City of New York have presented to the attention of the Court of General Sessions of the Peace, the Yellow Fever, and recommended that measures should be taken for the prevention of it.

It has been estimated in South Carolina, to take on an average 35 dollars per annum, to support a plantation slave; and that the average value of a slave is \$500.

In the village of Rochester, on Genesee River, N. Y. the first house was built in 1812. The village now contains 3000 inhabitants, has forty merchants' stores, six houses of public worship, a stone court-house, two factories, two printing offices, a paper mill, three iron foundries, six flour mills, six saw mills, an oil mill, two gun factories, a nail factory, two distilleries, and three tanneries.

A Huntsville, (Alabama) paper states that the quantity of Cotton grown, cleaned, and packed for market, in the county of Madison, in the state of Alabama, was, in the year 1821, upwards of six millions of pounds, amounting at the then market price of 12 1-2 cents per pound, to \$753,333. This year's crop, if equally abundant, will bring, at the present price of 8 cents per pound \$482,133. The population of that county, by the last census, taken late in 1821, was 17,481. The product for exportation, in 1821, was therefore within a fraction of forty-five dollars per soul, or, on a fair estimate, one hundred dollars for each working hand. The same rate would give to the Union a produce, beyond the consumption, of more than four hundred millions of dollars.

There are in a pond near Faversham, three trout, so domesticated, as to come at the call of the person who feeds them, and actually leap from their native element to eat out of the hand of their feeder.

At the Iron works of Truman Hart, Esq. in Pulteneyville, Ontario county, N. Y. there were manufactured in five days, at two fires, *forty-seven hundred* weight of wrought iron of various kinds.

Major William Howard, raised this season, on his farm in Kings' County, (L. I.) a turnip, weighing 7 lbs. 12 ounces, and measuring near thirty inches in circumference.

Three beautiful varieties of Tourmaline were deposited in the Cabinet of the Mineralogical Society in this town, last week, by Mr. Elijah L. Hamlin, of Paris, one of green, one of red, one of white, all taken from their native localities in that town. Also, a fine specimen of Emerald, of the subspecies Beryl, found in the same town.—*Portland Argus*.

James Pleasant, a member of the United States' Senate, is elected Governor of Virginia. The late president Madison was put in nomination, but declined being voted for.

ON GOVERNING THE PASSIONS

BY T. G. FESSENDEN.

"He that is slow to anger is better than the mighty;
and he that ruleth his spirit, than he that taketh a city."
SOLOMON.

The man who rules with absolute control
The angry passions, which deform the soul,
A more important victory can boast
Than he whose might has overcome a host.

The soul is sickened and the heart is pained
To trace the course of anger unrestrained,
Blasting the pleasures of domestic life
With bitter brawls, and scenes of savage strife.

The wretched wight, who yields to anger's power,
Has no security a single hour;
His life may soon be forfeited for guilt
Of guileless blood, in furious transport spilt.

Behold how bright the warrior's wreath appears,
Planted in carnage, fertiliz'd with tears!
And trace his trophies of heroic ire
Through seas of blood, and pyramids of fire!

Behold the conqueror, who won the world,
By ruthless rage from glory's zenith hurl'd!
Tost like a feather on the mountain wave,
Lord of the globe, but passion's paltry slave!

Then he who rules with absolute control
The angry passions, which deform the soul,
A more important victory can boast
Than if his might had overcome a host.

*Alexander the Great, in a fit of anger, slew his foster brother Clytus, for which flagitious act he was struck with such remorse, that he attempted to starve himself.

From the Boston Patriot.

HORSE SHOEING.

I have heretofore suffered much trouble and some danger, when riding on horse back in the winter time, from the horse having his feet loaded with balls of ice and snow; and I consider that horses driven in the stages often undergo a double share of fatigue and labor from this circumstance. I have for several years been endeavoring to devise some method to prevent or remedy this inconvenience; but without effect, until the year past; I directed my blacksmith to try the experiment of a shoe upon a different construction, and which I found to succeed so completely, that I wish to communicate it through your paper for the benefit of the public.

The smith in forming the plate for his shoe, should draw it wider in the middle and narrower at the end than for a common shoe. After the shoe is turned, let the inside of it be *peened* out, so as to leave it in the form of a *heater*, viz. narrow at the toe, and wide at the heel: In which case the snow, instead of being confined by a *circular* shoe and forming a ball in the hollow of the foot, is continually working out and discharging itself at the heel: and the horse instead of treading upon a round ball of snow and ice, will find and feel the benefit of his corks!

Printers who consider this improvement as worthy the attention of the public, will have the goodness to communicate it through their respective papers.

Hampton, Me. Nov. 29th, 1822.

From a late London paper.

CURED FISH.

Dr. Mac Culloch, of Edinburgh, has ascertained, that the antiseptic quality of Sugar is sufficient to preserve fish in the most excellent condition. He states that this substance is so active, that fish may be preserved in a dry state, and perfectly fresh, by means of sugar alone, and even with a very small quantity of it. He has thus kept salmon, whiting, and cod, for an indefinite length of time; and by this simple means fresh fish may be kept in that state some days, so as to be as good when boiled as when just caught.

It is added, that "if dried, and kept free from mouldiness, there seems to be no limit to their preservation; and they are much better in this way than salted. The sugar gives no disagreeable taste. This process is particularly valuable in making what is called *kippered salmon*; and the fish thus preserved are far superior in quality or flavor to those which are salted or smoked. If desired, as much salt may be used as to give the taste that may be required; but this substance does not conduce to their preservation. In the preparation it is barely necessary to open the fish, and to apply the sugar to the muscular part, placing it in an horizontal position for two or three days, that this substance may penetrate. After this it may be dried; and it is only necessary to wipe and ventilate it occasionally to prevent mouldiness. A table spoonful of brown sugar is sufficient, in this manner, for a salmon of five or six pounds weight; and if salt be desired, a tea spoonful or more may be added. Saltpetre may be used instead, in the same proportion, if it be desired to make the kipper hard."

From the National Gazette.

In "the General Views" contained in the Appendix to Mr. S. E. Morse's "New System of Geography," the following, among other interesting results, are stated in connection with the Tables of the Population of the United States.

In 1790, the States West of the Alleghany mountains contained scarcely one hundred thousand inhabitants—in 1820, those states, including Alabama and Mississippi, contained more than two millions of inhabitants.

The population of the United States has increased 32.9 per cent. between 1810 and 1820. At this rate it will double in about twenty-five years.

Taking the whole of the United States together, the Whites increase faster than the Blacks. During the last thirty years, the proportion has been as 117 to 133. But during the same period, in Maryland, Virginia, North Carolina, South Carolina, Georgia, Tennessee, and Kentucky, the Blacks have increased much faster than the Whites; in South Carolina, during the last ten years, more than three times as fast.

In the new States, the number of females is much less, in proportion, than in the old states. The difference is accounted for by the fact that the emigrants to newly settled lands, are generally young men, many of whom are without families. Hence the chances for marriage for females, are greater in the new than in the old states. In the latter, the number of females not married, is much larger in proportion than in the former.

Of the white population of the United States it appears that 12.17 per cent. are upwards of 15 years old, while, of the Black, the proportion is only 10.40 per cent. In the States south of Pennsylvania and the river Ohio, including Missouri and Louisiana, only 11.23 per cent. of the White population are more than 45 years old.

It appears that 2,065,499 persons in the United States, or more than one-fifth of the whole population, are engaged in agriculture; children and females generally not being included in the calculation. Only 421,644 persons, or 3.80 per cent. of the whole population, are engaged in commerce and manufactures, including not merely manufacturers in the common sense of the term, but mechanics and artificers of every kind.

In all our great cities, the females are more numerous than the males. The average of the cities gives nearly 109 females to 100 males, while that of the whole United States gives 97 females for 100 males.

In the six principal cities of the United States the proportion of females between 16 and 44 years of age, being on an average about 24 per cent. of the population, while in the country large, it is only 19.30 per cent. At the same time, the proportion of children under 10 years of age, is very small, being on an average 1 than 23 per cent., while the average of the whole United States gives 33.29 per cent. From this it appears that the causes which operate to retard the increase of population, exist to much greater extent in our cities than elsewhere. It is a singular fact, that in every one of the abovementioned cities, the females under 10 years of age are more numerous than the males, while in every State of the Union, the fact is reverse; and in the new States especially, the excess of males among the children is very great.

It appears that in the newly settled States Alabama, Mississippi, Indiana, Illinois and Missouri, taken collectively, there are, among children under ten years of age, 76,087 boys; 70,938 girls; that is, for every 100 boys there are only 92 girls; while in the old States New Hampshire, Massachusetts, Rhode Island, Connecticut, and the District of Columbia, there are 158,113 boys and 153,324 girls; that is, every 100 boys there are 97 girls; it appears also, that in our six larger cities, taken collectively, there are, under 10 years of age, 38,8 boys, and 38,223 girls; that is, for every 100 boys there are nearly 100 girls. This seems to indicate, that the state of society which is more favorable to the increase of population, is particularly favorable to the increase of males; perhaps, to be more particular, that the proportion of males among the offspring of early marriages is unusually great.

A gentleman riding through the town of— one day met an awkward fellow, leading a horse whom he accosted in the following manner: "How odd it looks to see one hog lead another!" "Yes, replied the chap, "but not so odd as does to see a hog ride on horseback."

Mrs. Garrick's letter of remonstrance against Kean's *Abel Druggier*, was brief. "Dear Sir you don't know how to play *Abel Druggier*." His reply deserves also to be recorded, and placed to the credit of his gallantry. "Dear Madam, I know it."

DISEASES OF CATTLE.

SELECTED AND COMPILED FROM THE BEST AUTHORS,
BY THE EDITOR.

Inflammation of the Stomach.

"The complicated structure of this organ, in ruminating animals, renders it peculiarly liable to disease; inflammation, however, does not appear to occur frequently as a primary disorder, but is more commonly a consequence of some offensive matter lodged in one of the four stomachs, or from the animal's feeding so greedily, as to weaken the organ, and prevent it from performing its functions. In either of these cases, the principal object is to get rid of the offensive matter, by invigorating the weakened stomach, and enabling it to expel the matter, by which it is oppressed. Should inflammation attack the stomach, independently of this cause, that is without any hurtful matter having been swallowed, or any improper accumulation of food, the principal remedies would be plentiful bleeding and abstinence from food."—*White's Treatise on Veterinary Medicine.*

Dr. Peck says that the symptoms of this disorder are violent pain in the stomach; large blisters rise sometimes on the inside of the mouth; the animal is very restless, and appears to have the pain increased by every thing that is swallowed, which frequently brings a cough; the body feels clammy with sweat; difficulty of breathing. He attributes the cause to overloading the stomach; cold water; acid matter, or poisonous substances; not sufficient water in dry summers. The treatment recommended by this author is to bleed freely every day, if necessary; keep the body open with castor oil, &c. afterwards give febrifuges [such as glauher's salt, nitre, salt of tartar, spirit of nitrous ether] as in other cases of inflammation. When the animal is recovering, give it food sparingly, a little warm, such as scalded malt with warm water, &c.

Inflammation of the Bowels.

The principal symptom of this disease is a griping pain, which causes the animal to lie down frequently, and rise with difficulty. He frequently turns his head towards his belly, and endeavors to strike it with his hind foot; the body is full; the eyes dull; the pulse strong and quick. The quickness of the pulse forms a distinction between this complaint and the gripes, in which latter disorder, the pulse is sometimes hard, but seldom quickened. When the pain is violent, a copious perspiration takes place.—When proper remedies are not employed, the disease terminates in mortification and death. In the treatment of this complaint, the circumstances of the case must be carefully attended to. If the pulse is much quicker than natural, the under surface of the eye-lid unusually red, and the breathing disturbed, let a large quantity of blood immediately be taken away, even five or six quarts; and then, unless the bowels are unusually open, give the following drink:

Sulphate of magnesia [Epsom salt], 3 oz.
Castor oil, 1 pint.
Gruel, 1 pint.

Dissolve the salts in the gruel, and add to them the oil, for one dose.

The operation of this drink should be assisted by clysters. When all the above symptoms, however, are not observable; if the under surface of the eye-lid is not redder than usual, or if it is rather pale; if the pulse is nearly in its natural state; and particularly if the animal is rather loose, or scours, the bleeding should be moderate; and if the animal be rather weak and in low condition, it had better be omitted. The following anodyne drink is to be given:

Tincture of opium, ½ oz.
Spirit of nitrous ether, 2 oz.
Water, 1 pt.

Mix for one dose.

When the animal has been kept sometime on dry food, and is apparently costive, relief can only be obtained by some laxative drink, like that first above mentioned, and clysters. Bleeding, however, must not be omitted, particularly if the pulse is quickened, the under surface of the eye-lid redder than natural, and the breathing disturbed. If the laxative prove ineffectual, in removing costiveness, it should be repeated.

Inflammation of the Liver.

"The structure of this organ in horned cattle and sheep, is different from that of the horse; the latter has no gall-bladder, but in the former, there is one of considerable size. It is on this account, perhaps, that cattle are more subject to diseases of the liver than the horse. I do not believe that inflammation of the liver often occurs in so acute a form, as to require bleeding largely; it is more commonly of a chronic or slow kind, causing a defective action in the organ, in consequence of which an unhealthy kind of bile is formed, which plugs up the ducts of the liver, and causes a derangement in the organs connected with it."—*White's Treatise.*

The symptoms of this disorder, according to Doct. Peck, are, difficult breathing; swelling about the short ribs; pulse hard, full and frequent; thirst; yellowness of the eyes; costiveness, &c. Fat beasts are most subject to this complaint in hot weather, by being overheated in driving, or running about the pasture; by being exposed to severe cold, when hot. The treatment recommended by Dr. Peck, is to bleed according to the symptoms; give cathartics, [purgers,] clysters, febrifuges, &c.; Diet, mashes made of scalded bran and malt; blister the sides of the belly, and rowel underneath.

Inflammation of the Kidneys

The following are the symptoms of this disorder:—quick pulse; loss of appetite; the animal is frequently endeavoring to stale, and voids only a small quantity with much difficulty and pain; pressure on the loins gives pain, and causes the animal to shrink or give way to it; there is generally, considerable stiffness in the hind parts, observable when the animal attempts to walk: the urine is commonly of a dark red color. This disease is, however, very different from that named red-water, [to be treated of hereafter] and unless properly treated at its commencement, often terminates fatally. Dr. Peck says, the symptoms that are of a favorable

nature, are, urine high, or of a coffee color, discharged in large quantities; afterwards copious, thick, and mixed with mucus. The unfavorable are, sudden cessation of pain; urine dribbling away in small quantities, of a black and fetid color and smell. The disorder is caused by violent blows across the loins; small stones or gravel being lodged within the kidneys; violent motion or hard driving in hot and sultry weather.

Let the animal be bled freely and take a pint of castor oil. If the dung is at all hard, or deficient in quantity, let clysters or warm water, with a little sweet oil, be employed. The liniment or embrocation, directed for inflammation of the lungs [see page 177, 3d column] should be rubbed on the loins; after which, let them be well clothed, or covered with a fresh sheep or lamb's skin. When the pain and difficulty, or rather the almost constant straining to stale continues, after the castor oil has operated, and the bowels have been sufficiently opened, an anodyne clyster may be administered, consisting of about one ounce and an half of tincture of opium, in one quart of gruel: or, from one dram to two of crude opium, dissolved in warm water, and mixed with gruel.

If the animal is very thirsty, he should be restrained from drinking; and what he takes should be impregnated with some mucilaginous substance; an infusion of linseed, or decoction of marsh-mallows is very proper.

Inflammation of the Brain.

This disease is a kind of madness, attended with ravings and constant watchings; slow respiration; a strong pulsation in the temporal arteries, and sometimes irregular; running at the nose; the animal appears in a very fierce state, as if seized with a turbulent kind of mania; the eyes appear much inflamed and ready to start from their orbits; the beast falls down of a sudden, and rises again with the same volatility, until nature is quite exhausted; a constant trembling and starting of the tendons; a dry and harsh skin; a suppression of the urine; grinding of the teeth, and a total want of rest; these last are unfavorable symptoms.

The cause of this disorder is found in too great an efflux of blood pressing on the temporal arteries; from which an increased action takes place; wounds or contusions on the head; suppressions of the natural evacuations.

The cure should be sought by bleeding freely, according to the violence of the symptoms and the strength of the animal, in the jugular-vein; keep the bowels open with castor oil, and other purging medicines. Blister the side of the neck with flies and spirits of turpentine.

From what has been said of the treatment of diseases, caused by inflammation of the internal organs of the body, it will be seen that they are all of a dangerous nature, and require the earliest attention; that they are generally the consequence of improper management or neglect, and may, therefore, most commonly be prevented; and that the most essential remedy is early and copious bleeding, with laxative medicine.

(TO BE CONTINUED.)

INTERNAL IMPROVEMENT.

CANAL FROM WORCESTER TO PROVIDENCE.

We have been kindly presented with a pamphlet entitled "An account of the proposed Canal from Worcester to Providence; containing the Report of the Engineer; together with some Remarks upon Inland Navigation. Published by order of the Committee for the County of Worcester;" and shall take some note of its contents, confining ourselves, however, principally to the facts which it contains. The project of opening inland navigation from the waters of Narraganset Bay, in Rhode Island, to Worcester, in Massachusetts, thro' the valley or basin of Blackstone river, was first attempted about the year 1796, by the late John Brown, who, with the aid of an Engineer, surveyed the route, and found the plan not only practicable, but easy of execution. Many intelligent gentlemen were disposed to aid in the work, but to effect it, an act of incorporation from each of the States of Rhode Island and Massachusetts, was necessary. The Rhode Island legislature passed an act, which vested a company with powers and privileges to prosecute the design, but the legislature of Massachusetts withheld its assent to a corresponding Act of Incorporation.

This vote of the Massachusetts legislature prevented for a time any farther attempts to carry the project into execution. Committees, however, have been recently appointed to investigate the subject, who engaged Benjamin Wright, Esq. Chief Engineer upon the middle section of the great Erie Canal, to make a topographical survey of the route. Mr. Wright, with the aid of two assistant engineers, completed a survey in September last, and made a Report from whence the following facts are obtained.

The distance over the route for the proposed Canal is 45 miles as a canal would run; and the descent is 151 1-2 feet, from Thomas-street, in Worcester, to tide water at Providence. The ground is remarkably favorable. The soil generally easy to excavate—the embankments neither large nor extensive—very little solid rock to be removed—the aqueducts and culverts are not numerous or expensive. A canal 32 feet wide at top, 18 feet at bottom, and 3 1-2 feet depth of water would be the proper size to be formed. Locks of 70 feet between the gates, and 10 feet in width, would be sufficiently large for the trade intended—bearing in mind a proper economy in the use of water, and in the erection of the locks. North Pond, lying two miles Northerly from the Court-house in Worcester, and Dority Pond, in Millbury, are calculated to be sufficient to afford, by means of dams erected at their outlets, lockage water for 19,602 locks of 3 feet lift each. Long Pond, which falls into Blackstone River, covers at least 1,500 acres, and may be raised 6, 8, or 10 feet above its present level, with a small expense, and would, in the greatest drought, secure an abundant supply for the Canal without injuring, in the smallest degree, the important manufacturing interests along the Blackstone and its branches.

The whole expense, as reported by Mr. Wright, will amount to \$323,319. In this estimate is included \$15,395 for contingencies.

We shall conclude this notice by the following extracts, given verbatim from the pamphlet before us:

"The Report states that 'the ground is remarkably favorable—the soil generally easy to excavate—the embankments neither large nor extensive—very little solid rock to be removed, and the Aqueducts and Culverts not numerous or expensive;' and it may be added that the route is remarkably direct. This fully accounts for the estimates of the Engineer, falling short of public expectation.

"The plan, then, is feasible, the supply of water abundant, and the expense much less than was contemplated; the only question, therefore, which remains to be settled is, whether it is *expedient*? On this point, those who have most carefully and deliberately examined the subject, would almost consider it heresy to doubt, so manifest are the advantages, and so obvious the importance to a large and fertile section of the country, whose prosperity probably experiences a severer check from the high charges for transportation on tonnage than from any other single cause. It is probable the question of expediency would not have slept, under the decision of the Legislature in 1796, until this time, without a renewed application for an Act of Incorporation, had there not been, during a large portion of that period, a peculiar concurrence of circumstances, which probably will not again recur."

"It is calculated that the expense of transporting on a Canal, exclusive of tolls, amounts to ONE CENT a ton, per mile, or *one dollar a ton*, for one hundred miles, while the usual cost of conveyance by land, is *one dollar and twenty five cents per hundred weight, or twenty-five dollars a ton*, for the same distance. "The celerity and certainty of this mode of transportation are evident. A loaded boat can be towed, by one or two horses, at the rate of twenty-five or thirty miles a day. Hence, the seller or buyer, can calculate, with sufficient precision, on his sale, or purchases—the period of their arrival—the amount of their avails, and the extent of their value. A vessel on a Canal is independent of winds, tides and currents, and is not exposed to the delays attending conveyances by land; and with regard to safety, there can be no competition. The injuries to which commodities are exposed, when transported by land, and the damages to which they are liable, when conveyed by natural waters, are rarely experienced on Canals. In the latter way, comparatively speaking, no waste is incurred, no risk is encountered and no insurance is required. Hence it follows, that Canals operate upon the general interests of society, in the same way that machines for saving labor do, in manufactures. They enable the Farmer, the Mechanic, and the Merchant, to convey their commodities to market, and to receive a return, at least *twenty-four times cheaper, than by roads*," [exclusive of tolls, which are usually very moderate.] "As to all the purposes of beneficial communication, they *diminish* the distance between places, and therefore encourage the cultivation of the most extensive and remote parts of the country. They create new sources of internal trade, and augment the old channel; for the more cheap the transportation, the more expanded will be its operation; and the greater the mass of the products of the country for sale, the greater will be the commercial exchange of returning merchandise, and the greater the encouragement to Manufacturers by the increased economy and comfort of living, together with the cheapness and abundance of provisions and raw materials. Consequently, Canals are advantageous to towns and villages, and to the whole country, by increasing population, augmenting individual and aggregate wealth, and extending foreign commerce."

Many who find the day too long, think life too short. But short as life is, some find it long enough to outlive their characters, their constitutions, and their estates.

AGRICULTURE.

From the Middlesex Gazette.

At a meeting of the Trustees of the Society of Middlesex Husbandmen and Manufacturers, holden at Concord, Jan. 1st, A. D. 1823, the following premiums were awarded:

To Col. Joseph Valentine, of Hopkinton, the sum of fifteen dollars, for the greatest quantity of Indian corn, raised on one acre of land, being 119 bushels, 3 pecks and 2 quarts. [For the soil and process of cultivation, see our last, page 178.]

To Ebenezer Little, of Shirley, the sum of ten dollars, for the next greatest quantity of Indian corn raised on one acre, being 66 bushels.

To James Kimball, of Littleton, the sum of seven dollars, for the greatest quantity of Barley raised on one acre of land, being 40 1-2 bushels of heavy two-rowed barley, weighing 50 lbs. the bushel.

Several other claims for premiums on Agricultural experiments were laid before the Trustees, and were deferred for further consideration, to the adjourned meeting of the Trustees, which will be holden at Darrah's Hotel, in Concord, on the 11th day of March next.

Agreeable to a vote of the Society in 1821, the Treasurer has distributed among some of the most intelligent and attentive farmers in the County, a quantity of Chili wheat and Riga flax-seed, for the purpose of having their value tested by various experiments. Seven of the persons, who received some of the wheat and flax-seed, have made reports to the Trustees, and although the experiments have been made in different parts of the county, and on a variety of soils, the result of each has been nearly the same. The wheat has in every instance failed. It grew with great luxuriance and apparent health and vigor, and seemed to promise an abundant product; but in each case there has been a general blast of the grain—no kernels have been produced which will equal either in size or fairness, those which were sown.

The success of the flax has been different. In every instance it has far surpassed any which has been ordinarily cultivated in this county. That which was sown on a rich soil grew to the height of six feet, and arrived at maturity in due season. No facts have yet been communicated from which the quality of the flax when fully prepared for the spindle, can be determined with certainty, but it is believed that it will be much superior to the flax usually raised in this vicinity.

By order of the Trustees,

N. BROOKS, Rec. Sec.

Description of a method of cultivating Peach Trees, with a view to prevent their premature decay; confirmed by the experience of forty-five years, in Delaware state, and the Western parts of Pennsylvania. By Thomas Coulter, Esq. of Bedford County, Pennsylvania.

From the Transactions of the American Philosophical Society.

The death of young peach trees is principally owing to planting, transplanting, and pruning the same stock, which occasions it to be open and tender, with a rough bark, in consequence of which insects lodge and breed in it, and birds search after them, whereby wounds are made, the gum exudes, and in a few years the tree is useless. To prevent this, transplant your trees

as young as possible, if in the kernel it will be best, as there will then be no check of growth. Plant them sixteen feet apart. Plow and harrow between them, for two years, without regard to wounding them, but avoid tearing them up by the roots. In the month of March or April, in the third year after transplanting, cut them all off by the ground, plow and harrow among them as before, but with great care, to avoid wounding or tearing them. Suffer all the sprouts or scions to grow, even if they should amount to half a dozen or more, they become bearing trees almost instantaneously, on account of the strength of the root. Allow no animals but hogs to enter your orchard, for fear of their wounding the shoots, as a substance drains away through the least wound, which is essential to the health of the tree, and the good quality of the fruit.

If the old stock is cut away the third year after transplanting, no more shoots will come to maturity than the old stump can support and nourish, the remainder will die before they bear fruit, and may be cut away, taking care not to wound any other stock. The sprouts when loaded with fruit will bend, and rest on the ground in every direction for many years, all of them being rooted as if they had been planted, their stocks remaining tough, and their bark smooth, for twenty years and upwards. If any of the sprouts from the old stump should happen to split off and die, cut them away, they will be supplied from the ground by others, so that you may have trees from the same for 100 years, as I believe. I have now trees from one to thirty six years old, all from the same stump. Young trees, formed in this manner, will bear fruit the second year; but this fruit will not ripen so early as the fruit on the older trees from the same stump. Three years after the trees are cut off, the shoots will be sufficiently large and bushy to shade the ground so as to prevent the growth of grass, that might injure the trees: therefore ploughing will be useless, and may be injurious by wounding them. It is also unnecessary to manure peach trees, as the fruit of manured trees is always smaller and inferior to that of trees which are not manured. By manuring you make the peach trees larger, and apparently more flourishing, but their fruit will be of a bad kind, looking as green as the leaves, even when ripe, and later than that of trees which have not been manured. Peach trees never require a rich soil: the poorer the soil the better the fruit: a middling soil produces the most bountiful crop. The highest ground is the best for peach trees, and the north side of hills the most desirable, as it retards vegetation, and prevents the destructive effects of late frosts, which occur in the month of April, in Pennsylvania. Convinced, by long experience, of the truth of these observations, the author wishes they may be published for public benefit, and has been informed, that Col. Luther Martin and another gentleman, in the lower part of Maryland, have adopted a similar plan with great advantage.

REMARK BY THE EDITOR.

☞ The method here described of managing peach trees will probably supply some useful hints for the culture of apple and other fruit trees. Old orchards might be renewed by cutting away in the proper season the old stocks, and leaving the most vigorous sprout to renew

the stock, or making use of the stump to ingraft upon; if the fruit be not of the best quality.—New varieties of fruit, however, ought to be occasionally sought for from the seeds, as ingrafted fruits in process of time degenerate. A valuable paper on this latter subject may be found in the Transactions of the Society for the Encouragement of Arts, Manufactures and Commerce, written by Thomas Skyp Dyot Bucknall, Esquire, and republished in the Repertory of Arts, 2d Series, vol. 2. p. 361.

Account of a method of preventing the premature decay of Fruit Trees. By John Ellis, of New Jersey.

From the Transactions of the American Philosophical Society.

The decay of peach trees is owing to a worm, which originates from a large fly, that resembles the common wasp: this fly perforates the bark, and deposits an egg in the moist or sappy part of it. The most common place of perforation is at the surface of the earth, and, as soon as the worm is able to move, it descends into the earth, probably from an instinctive effort to avoid the winter's frost. This may be ascertained by observation, the track of the worm from the seat of the egg being visible at its beginning, and gradually increasing, in correspondence with the increasing size of the worm; its course is always downwards. The progress of the young worm is extremely slow; and if the egg is deposited at any considerable distance above the surface of the earth, it is long before the worm reaches the ground. The worms are unable to bear the cold of winter unless covered by the earth, and all that are above ground after frost are killed.

By this history of the origin, progress and nature of the insect, we can explain the effects of my method, which is as follows. In the spring, when the blossoms are out, clear away the dirt so as to expose the root of the tree, to the depth of three inches: surround the tree with straw, about three feet long, applied lengthwise, so that it may have a covering one inch thick, which extends to the bottom of the hole. The but-ends of the straw resting upon the ground at the bottom. Bind this straw round the tree with three bands, one near the top, one at the middle, and the third at the surface of the earth; then fill up the hole at the root with earth, and press it closely round the straw. When the white-frosts appear, the straw should be removed, and the tree should remain uncovered until the blossoms put out in the spring.

By this process the fly is prevented from depositing its egg within three feet of the root, and although it may place the egg above that distance, the worm travels so slow that it cannot reach the ground before frost, and therefore is killed before it is able to injure the tree.

The truth of the principle is proved by the following fact. I practised this method with a large number of peach trees, and they flourished remarkably, without any appearance of injury from the worm, for several years. I was then induced to discontinue the straw with about twenty of them. *All those which are without the straw have declined, while the others, which have had the straw, continue as vigorous as ever*

FOR THE NEW ENGLAND FARMER.

It is not unfrequent to hear complaints of exorbitant taxation, and that the demands of pauperism form no inconsiderable item of the requisition, without the least advance to better the financial policy of towns in this particular. Many have been long accustomed to stipulate for the yearly maintenance of their paupers by auction, or other similar contract; a method, uniting great trouble with much expense. It is believed the adoption of other more judicious means would better subserve that beneficence embraced by the laws of humanity.

Therefore, to avail ourselves of the experience of past times, is a highly incumbent duty, so far as it will subserve the cause of humanity, and lighten the burthen of pauperism.

Should towns, having any considerable number of poor, provide lands proportioned to their wants and capacity, and place them under the superintendence of a practical farmer, aided by the united exertions of the most healthy of the paupers, it is believed that their labors, would in no small degree, contribute to the support of the whole.

The propriety of employing a practical farmer is self-evident—for to the profession of agriculture, he unites economy and industry, the most important requisites in such an establishment—and is a judge of the kind and quality of the different soils that may fall to his care, and their adaptation to the several growths of profitable vegetables; also, his knowledge of the working part would enable him to make just exactions of others.

An attention to the breeding of swine, is an important acquisition, for while it regulates the pigery, it contributes largely to the accumulation of manure, without which, profitable returns cannot be expected from culture.

Manure being the mainspring in agriculture, an attention to it is of the highest importance, whether of inland location, or contiguous to the sea board—the latter, however, combines many advantages in that particular, not comprised in the former, as large collections might easily be made from sea and rock weed, dock mud, and many other floating substances possessing salt and other qualities important, whether for compost or other manure.

Establishments for the reception and maintenance of paupers on a somewhat similar plan, would no doubt greatly lighten taxation, and contribute to the comfort of the dependant, while under the guidance of sound policy, bottomed on benevolent principles, together with a well regulated police, essentially necessary to the health and comfort of old age, poverty and decrepitude would rarely be deprived of the necessities and comforts of life, while the wants of the indigent would be provided for, at little or no expense to the community.

A MIDDLESEX HUSBANDMAN

From the Columbian Star.

There is a practical infidelity abroad, which derides the idea of Divine Providence. Whatever calamity may happen, "forth steps the spruce philosopher," and descants learnedly on the causes which have produced it; and he is satisfied with the most absurd conclusions, if he can succeed in excluding the all-sustaining and controlling Sovereign of the Universe from any agency in the event.

FOR THE NEW ENGLAND FARMER.

ON THE PRESERVATION OF THE TEETH.

Keeping the teeth clean is indispensable to their preservation. By suffering the particles of food and other impurities which are constantly collecting about them to remain, is to favor the production and operation of those causes which effect their ruin.

Whatever then is best suited to keep them clean, without the power of injuring them, is also best calculated to prevent their discoloration and decay. The same causes which produce caries of the teeth, tend likewise to injure the gums and breath, rendering the latter offensive, the gums spongy, and detaching them from the teeth. Most of the imported tooth powders, and those whose composition is kept secret, possess some acid property, or grinding power, which hurts the teeth by corroding or abrading the enamel, or protecting surface of them, leaving the comparatively soft and bony part within, to turn black and perish, without the possibility of the tooth's being restored to a sound state. These dentifrices often give the teeth an unnatural whiteness and brilliancy, very pleasing at first, and for a time, before their real character and effects are suspected. All that any preparation of this kind was ever intended to accomplish, by any one excepting an impostor, is to keep the teeth clean, of a natural whiteness, the gums sound, and the breath sweet.

All these effects the following powder is well suited to produce, without its possessing any quality which can, in any length of time or freedom of use, occasion the smallest injury of any sort. From its well known property of sweetening putrid and offensive substances, charcoal has latterly been, by some, much commended, and by many used as a dentifrice. After some time however, its particles were found to possess a grinding power, from their hardness, which soon wore off the enamel.

Engravers avail themselves of this property of finely pulverized charcoal, to grind down and polish their plates.

THE TOOTH-POWDER.

Take of Peruvian bark	2 parts.
Armenian bole	4 "
Prepared chalk	4 "
Myrrh	2 "
Loaf sugar	2 "
Carbonate of soda	$\frac{1}{2}$ a part.
Castile soap	2 parts.

These are to be pulverized, mixed, and passed through a sieve. Any apothecary can furnish this tooth-powder.

TOOTH BRUSHES.

The brush with which this powder is to be applied, should be sufficiently large and firm, and the hairs not too closely placed.

One reason for preferring hard brushes is, that they become softer by use, and another is that if not pretty stiff, they are not firm enough to clean the teeth thoroughly. They are never too hard unless they are so unyielding as to insinuate themselves between the teeth and gums, so as to separate them; this being guarded against, the firmer they are the better.

Having thus provided the powder and brush, the question is, how are they to be used?

The mouth should be rinsed with cold water, and the brush dipped into it before the powder

is used. A quantity of the powder should then be taken up on the end of the brush, and applied to every part of each tooth, not only to the anterior surface of the fore teeth, but the brush covered with the dentifrice, should be successively applied to the inner, as well as the outer, surface of the upper and lower teeth, and also to their ends. The last motions of the brush should be carried from the gums to the ends of the teeth, in the direction of their length. This serves to elongate the gum and to spread its points more elegantly over the enamel. The best time for using the tooth powder is after breakfast, and this should be done every day. In addition to this, we should be careful to cleanse the mouth with water and the brush, after every meal; and this should be particularly attended to before going to rest, otherwise the foulness which is too often permitted to accumulate through the day, cannot fail to commit its ravages on the teeth, gums and breath thro' the night. Benserade, a Frenchman, said of a young lady, who had a very strong breath, whom he heard sing, "What a beautiful voice, and charming words, but the air is worth nothing." Mais l'air n'en vaut rien.

Brushing the teeth once a day, if faithfully done, is preferable to many hasty and imperfect attempts to clean them.

Merely to pass the brush a few times lightly and rapidly over the teeth, is of little service; four or five minutes should be diligently spent in performing this operation.

The idea that the enamel of the teeth can be injured by brushing, is as unfounded and absurd as it would be to suppose that the palms of the hands might be worn out by moderate labor.

The same grateful and refreshing sensations which result from bathing the surface of the body, arise also from a proper attention to the mouth. No one who neglects his mouth can be said to be personally neat; nor can any one who omits this necessary attention to himself, justly expect the *voluntary* attention of others.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR,

I send you the following extract from a Memoir read before the Royal Academy of Sciences, as tending to show the great exertion, as well as the royal patronage, which is exercised in France, for the improvement of their manufactures. Though the success which attended this effort was not so complete as could have been wished, yet it appears to have settled a question as to which no satisfactory information could be before obtained. It had long been a question with the curious what animal produced the material of the Cashmere (or by some called Camel's hair) shawl, of which we see generally only those of the cheaper kind. The time taken as well as the intricacy of the manufacture giving to them a most prodigious value. It will be seen that the individuals in this expedition passed thro' Russia and Tartary. In Tartary was found the goat which produced this remarkable fleece, in the possession of some wandering tribes, who gave them the name of the Thibet goat. Thus the labor was prevented of passing to Thibet, Persia or Cashmere in India. It seems four hundred of these animals were brought to France, being only about one third of the number purchased. How far they may retain the fineness of their down in France, and what the utility in manufactures may be, time only can discover. It will be very long before the subject can be immediately

important to us. But the knowledge cannot fail to be very interesting to such of your readers as have not seen this memoir. It goes to establish a fact as to which there was till of late great doubt, and is indeed an object of much curiosity and gratification. W.

Cashmere Goat, and its Importation into France.

The sight of these shawls, which are brought from Asia, and which spread all over Europe, make a part in the presents of the sovereigns of the east, and adorn the heads and waists of the rich inhabitants of those countries, gave rise to the question among the naturalists of Europe, what species of animal produced the material from which such precious stuffs were made.— Travellers gave no satisfactory information upon this subject. The general opinion was, that cashmeres were produced from a goat, but the particular species was not determined. The importation which has just been made clears up, in part, this difficulty, for these animals produce a down exactly like that of which the most rare shawls are made; I say in part, because it is not impossible that wool may be also employed for this purpose, or that different kinds of the goat may unite to bring the manufacture to perfection. I shall describe particularly those which I have seen upon their arrival at two of our Mediterranean ports.

Their usual height is about 25 inches from the ground to the top of the back, and the length from the beginning of the tail to the head, three feet. Almost all have horns, which are straight, black, and for the most part round; those of some males, as well as females, are thick, furry, white in the majority of individuals, some brown or black, several spotted. They are formed of long hairs, which cover the legs, in part, and a very soft down. The latter is fine in proportion as the hair is long; the quality of one may be known from the other. This down grows near the skin, from which it separates and forms tufts, which can be drawn away by a comb or by the hand. Except in the case of an absolute prohibition, it appears as if our manufacturers could have no interest in importing these downy cashmere goats into France, for the material may be procured in the way of commerce: it would be sufficient for them to imitate the stuff which bears this name. M. Ternaux, so well known by his beautiful establishments, was not of this opinion. He had received, by the way of Russia, down enough to make some shawls; his success gave him the idea of procuring the animal on whose body nature had placed this down. The undertaking was not an easy one. He found in M. Jaubert, Master of Requests, and Professor of the Turkish language, a man of zeal and intelligence, who was not to be repulsed by obstacles, and who was much attached to this country. This gentleman had already travelled in the Levant, and could make himself understood among the different nations. He was willing to undertake the expedition.

In order to obtain the protection of Government, M. Ternaux presented him to the Duke of Richelieu, then Minister of Foreign Affairs. This Minister, who acknowledged the utility of the project, made a contract with Ternaux and Jaubert, in the name of the King, by which Ternaux was to receive a premium of encouragement if the expedition succeeded. The Government was to take a hundred goats at a

price. In consequence of this, Jaubert Paris in the month of April, 1813, recommended by the Duke of Richelieu to the notice of the Emperor of Russia. This Sovereign gave orders in his dominions that the French Consul should be furnished with all the facilities he needed. Jaubert went first to Odessa, Bessarabia, and Astracan, to the camp of General Jermoloff, under the Caucasus, taking everywhere information from the Boukars respecting the Kirghiz and the Armenians, who frequent and inhabit the last of the cities. He was informed that there existed among the numerous hordes of Kirghiz (a wandering people who are called Boukaria,) on the borders of Oueal, a species of goat which was almost always of a dazzling whiteness, and which bore every year, the month of June, a remarkable fleece.—The samples shown him convinced him of the conformity of this down with that which came to France by the way of Russia.

The discovery was the more interesting to him, as it saved his time and a troublesome journey in crossing into Thibet, by Persia and Cashmere. He was not deceived, and in some hundred versts from the Wolga, in the middle of the Steppes, which separated Astracan from Semurgu, he found thick down, which convinced him that he would not find it necessary to go much farther. He also remarked that they gave them the name of Thibet goats, in the language of the country, when they spoke of them. He then made his purchases, buying different lots among the Kirghiz of the horde called Cara Agedi (the black tree,) among the Kirghiz of the horde called Kaskas, in all 229 beasts. He directed his troop towards Zaritzin, where he passed the river Wolga. The season became severe, and the mortality among the goats was very great. He had formed a plan of embarking them at Turgarock, but the sea of Azoff was frozen. He was obliged to go along the coast with them to Theodor or Cassa. He arrived there the 24th of December, after having lost 263 of his animals.—The 14th of February he sent, in a Russian vessel, the only one he could procure, 566, together with some Austrian sheep, under the care of a French supercargo. The vessel arrived at Marseilles towards the month of April: Jaubert preferred not to come until he could bring the second troop, which he did not choose to leave behind.

It results from the experiment of Jaubert and Bernaux, that from 1,229 goats bought among Kirghiz, deducting all the losses which have taken place, there are at present in France 400 waxy goats of Cashmere.

From the Hallowell Advocate, Jan. 4.

In the Advocate of last week I observed a communication from Samuel Preston, of Pennsylvania, to the publisher of the New England Farmer, wherein allusion is made to a demonstration of friend Preston's rules for gauging published in the Advocate of 8th Nov. last. The author of that demonstration is pleased to see the reasons for the rule given in that communication by the person who invented or discovered it. The *Rationale* of the rule are satisfactory except that it is not perceived how the reasons for performing division by multiplication depend on the neutral properties of an unit. The principle as laid down by friend Preston, of per-

forming division by using a fraction, either common or decimal, as a multiplier, is familiar; but how this depends on the neutral properties of the unit is not readily comprehended. As Mr. Preston, from the tenor of his communications, seems to be a man of some science and ingenuity, and no doubt can fully explain his meaning, it is hoped he will make a more full and minute explanation of his ideas upon the neutral properties of the unit. The relations and properties of numbers are of that abstract nature, that more minute explanation is frequently required to convey ideas to others, than the person in full possession of them deems necessary. But as Mr. Preston has pledged himself to "explain and render" his rule (and of course all his reasons for it) "intelligible to any person master of the common rules of arithmetic," we have no doubt but his ideas upon the neutral properties of the unit, will be made public.

The writer of this would have no objection to a correspondence with any gentleman of intelligence upon a favorite science. Should Mr. P. mean to allude to any other than a public correspondence, and such a wish should be hereafter expressed, the name and residence of the writer of this, can be given him, through a channel of the writer's own choice. C.

On the danger of using vessels of Lead, Copper, or Brass, in Dairies. By Mr. Thomas Hayes, Surgeon, of Hampstead.

From the Letters and Papers of the Bath and West of England Society for the Encouragement of Agriculture, &c.

Many eminent physicians have asserted, that butter is very unwholesome; while others, equally eminent, have considered it not only innocent, but as a good assistant to digestion; and each have been said to ground their opinions upon experience. Perhaps both may be right; and butter may be innocent or mischievous, according as it contains many or few adventitious materials, collected from vessels, &c. used in the process of making it.

I am led to these conjectures by observing, that in almost all the great dairies, the milk is suffered to stand in lead, brass or copper vessels, to throw up the cream. The closeness of the texture of these metals, and their coldness and solidity, contribute to separate a greater quantity of cream from the milk than would be done by wooden trundles, or earthen pans, both of which are also sometimes made use of.

As I wish to establish the possibility of the fact, that milk may corrode or dissolve particles of the vessels above mentioned, and thereupon be liable to communicate pernicious qualities to the butter, I beg leave to submit the reasons from which I draw this conclusion.

Whoever has been much in great dairies must have observed a peculiarly sour, frowsy smell in them, although they have been ever so well attended to in point of cleanliness, &c. In some, where the managers are not very cleanly, this smell is extremely disagreeable, owing mostly to the corrupted milk. In some it arises from the utensils being scalded in the dairy, and in others from a bad construction of the building itself, the want of a sufficient circulation of air, water, &c. but in all, a great deal of the lighter and more volatile parts of the milk fly off from the surface of the pans, and furnish a great quantity of acid effluvia to the

surrounding air and ceiling; which is again deposited on every thing beneath it, and of course often on the vessels, after they have been put by clean, at the times of their being out of use. This may be observed to give a dull sort of an appearance to brass and copper, as if you had breathed upon them; for if you rub your fingers lightly over the vessels, you will have both the taste and smell of the metal.

It also happens sometimes, that after the vessels were washed, they are not carefully rinsed, nor perfectly dried by the fire; so that some of the milk, &c. is left on their surface, which dissolves the metals, either by its animal, oily, or acrescent qualities.

This is not the only way, nor the worst, by which the butter may become impregnated with mischief. The greater the quantity of cream thrown up from the milk, the larger the profit accruing to the dairy-man; therefore he keeps it as long as he can, and it is frequently kept till it is very sour, and capable of acting upon them; if they are of lead, a calx or sugar of lead is produced; if brass or copper, verdigris.

It is true that the quantity cannot be very great; this, however, will depend upon the degree of sourness, and length of time which the milk stands; but, independent of the acid, the animal oil in the cream will dissolve brass and copper.

That an acid floats in the atmosphere of a dairy, may be proved, by placing therein a bason of syrup of violets, for a little time, which will be found to turn red.

If then I am right in my conjectures, as I think I am, from the innumerable experiments and observations which I have made to satisfy myself of the fact, and which it would be trifling to relate here, may not the reputation of wholesomeness, or unwholesomeness of butter depend upon, or be owing to some of the above causes? And may not many a casual, nay, obstinate complaint, which physicians have labored in vain to account for, have originated from this source? Butter is found, very frequently, to occasion much disorder to very weakly, delicate and irritable stomachs, yet these stomachs will bear olive-oil: this cannot easily be accounted for, but from metallic impregnation.

I will not contend, that all the ill effects attributed to butter are caused by the mineral particles, which it gains by the means above stated. I only insist that it is possible, and indeed very probable; and that, when butter is free from these particles, it is not so unwholesome as asserted; though, when it does not contain them, it is found to disorder very tender persons.

To enlarge upon the subject, or attempt to explain the many ways by which a very small quantity of the above metals may prove injurious to the human frame, in some particular constitutions, would be only to repeat what has already been said by older writers*. Some will perhaps say that my ideas are very far fetched, and others that my opinions are ill-founded; but I trust, whoever has read the illustrious researches of Sir George Baker, on the effects of lead, and the melancholy case of a young lady, who died from eating pickled sapphire, very slightly impregnated with copper, and which others ate without being diseased, as related by Dr.

* See Sir George Baker's papers on the effects of lead, in the Medical transactions; Dr. Percival's paper on the same; and Dr. Falconer on copper vessels.

Percival, will receive my opinions with less objection. If I have erred, I have done it in honorable company.

I shall be very glad if the foregoing observations have sufficient influence on the dairy-men, to induce them to change their utensils. Very commodious vessels may be made of cast iron, equally well fitted for the purposes of the dairy, which will not be expensive, and will be more innocent and cleanly.

From the Connecticut Courant.

Useful but disagreeable hints on the approach of a New Year.

There is much good sense in the adage "frequent reckoning makes good neighbors." Settlements, however, are often postponed, because there is some trifling disagreement between the parties; and to look over old accounts is a dry undertaking. Add to this our propensity to put off 'till to-morrow, and the too prevalent grossness of feelings regarding the high obligations of justice, and we find the root, from whence spring many bitter quarrels and lawsuits. Wherefore, gentle reader, hear the voice of experience.

Fix on the *first day of January, every year*, as a date, beyond which no controversy of yours shall remain unsettled "so far as in you lies."

If your books are back, take care to have them "posted up" by that day.

If you find any person's account open, which has been paid, *balance it*.

Where the balance is against you, saddle your horse and go directly off and *pay it*—in money if you have it—if not, give your note.

Take especial care when your good easy neighbor, confiding in your honesty, has let his claim lie more than six years, not to permit that plea of rascals, "outlawed," to reduce you first to doubt whether it is due, and finally to offer to settle it, "if he will throw in a trifle." Pray, why did you not pay him before, when his witnesses were living, and the facts fresh? Such claims ought to be paid with interest, and that without delay, lest you die and the executor refuse to pay.

Where the balance is in your favor, do not, by any means neglect such a claim. 'Tis true, your neighbor may have said "he would take no advantage;" but he may die, or forget, or find on seeing your bill that "it is larger than you expected," and he may think you have omitted some credit. You do not meet on even ground.

Is there any matter that lies between you and any one of *doubtful honesty*? I beg of you to see well to that. Such a man, especially if poor, will have a heavy claim *against your estate*, in the event of your decease. Get a discharge from him, and call it even, though he may owe you a trifle. A release from such persons is as good as bank stock.

Finally, let not the light of another new year's morning rise upon you, until you shall have remitted "post paid" all you owe to *proprietors of newspapers*. Those are honorary claims, especially if due out of the state. Should the press stop for want of funds, the land will soon grow dark. You expect a pleasant song from them on that morning—but how can they sing if depressed with debt? They must "hang their harps on the willows," unless "cheered by your corn and your oil." ARISTIDES.

THE FARMER.

BOSTON:—SATURDAY, JAN. 11, 1823.

ON SAVING AND MAKING THE MOST OF MANURE.

(Continued from page 175.)

In our last number on this subject we adverted to WATER and EARTH, as the principal *absorbents* or *treasurers* of those particles or atoms, which constitute *manure*, or what is the same thing, the *food of plants*. We shall now proceed to further observations on those substances, considered as absorbents, treasurers, or receptacles of manure.

Water in its purest state, when it has been distilled, or filtrated through sand, still retains somewhat of the food of plants. Its component particles, oxygen and hydrogen, under certain circumstances, are seized by vegetables while in their growing state, and converted into the products which form the chemical constituents of all vegetables.* But pure water forms a meagre diet for plants. It may support life in vegetables, and some plants will maintain a feeble growth with very little nourishment excepting what is afforded to them by pure water and air. But when water is impregnated with certain salts and gases, particularly such as are evolved during the fermentation and decomposition of vegetable and animal substances, it becomes what is called LIQUID MANURE. Urine, or the stale of all animals is water holding in solution certain salts and other substances, which are the *essence of manure*, or the food of plants, in a concentrated state. Fresh urine is a very powerful and efficacious manure, when properly applied, but if not mixed with solid matter it should be diluted with water, as when pure it contains too large a quantity of animal matter to form a proper fluid nourishment for absorption by the roots of plants.—Urine is lessened in value, but its useful qualities are not entirely lost, by putrescence. During putrefaction the greatest part of the soluble animal matter that urine contains is destroyed, it should therefore be used as fresh as possible, with the precaution of diluting it with water, or mixing it with earth. Putrid urine, however, is a valuable manure. It abounds in ammoniacal salts; and though less active than fresh urine is still very efficacious.†

According to some writers, and practical farmers, the value of the urine of cattle, if properly preserved and applied to the purposes of vegetation, is greater than that of all the dung which the same animals would yield! A letter from Charles Alexander, near Peebles, in Scotland, addressed to Sir John Sinclair, in 1812, for publication, contains much valuable information on this subject. "This intelligent farmer had long been impressed with the great importance of the urine of cattle as a manure, and he set about to discover by a long and well conducted series of experiments, the best method of collecting and applying it. He began by digging a pit contiguous to the feeding stall, but distinct altogether from that which was appropriated for the reception of the dung. The dimensions of this pit, according to his own account, were 36 feet square, and four feet deep, surrounded on all sides by a wall; and the solid contents were 192 yards. Having selected the nearest spot where he could find loamy earth, and this he always took from the surface of some field under cultivation, he proceeded to fill it; and found that with three men and two horses, he could easily accomplish 20 cubic yards per day; and the whole expense of transporting the earth did not exceed 4l. 16s. sterling, [about 22 dollars.] When the work was com-

* See an account of M. Braconnet's experiments, p. 131.

† See Darg's Agricultural Chemistry.

plete he levelled the surface of the heap in a line the sewer, which conducted the urine from the interior of the building, on purpose that it might be distributed with regularity, and might saturate the whole from top to bottom. The quantity conveyed to it he estimated at about 800 gallons; but as this calculation founded partly on conjecture, for he measured not liquor, it will be better and more instructive to find and proceed on DATA that are certain and incontrovertible. The urine was supplied by fourteen casks weighing about 34 stone [476 lbs.] each, and here for five months on fodder and turnips. The contents of the pit produced 238 loads, allowing two casks to be taken out in three carts; and he spread of these on each acre, so that this urine in five months and from fourteen cattle, produced a compost sufficient for the fertilization of seven acres of land. He states further, that he had tried this experiment for ten years and had indiscriminately used in the same field either the rotted cow dung or the saturated earth; and in stages of the crop he had never been able to find a perceptible difference. But what is still more wonderful, he found his compost lasted in its effects as many years as his best putrescent manure; and he there boldly avers that a load of each is of equivalent value.

It appears, then, that in five months each cow charges urine, which, when absorbed by loam, furnishes manure of the richest quality and most durable effects for half an acre of ground. The dung pit, which contained all the excrementitious matter of the fourteen cattle, as well as the litter employed in bedding them, and which was kept separate for the purpose of the experiment, only furnished, during the same period, 240, and these, at the same rate, could only manure six acres. The aggregate value of the urine, therefore, when compared with that of the dung, was in the ratio of 7 to 6; so that we are borne out by the premises in this extraordinary inference, that the putrescible liquor, which in this province [Nova Scotia] and under the management of our farmers, is wasted and annihilated as far as regards any useful purpose is intrinsically worth more than the dung, as an efficacious and permanent dressing; and if we take into consideration that this latter manure is not treated with any skill and judgment, it will not seem surprising that the culture of white crops has never been carried here to any extent, since we have despised and neglected the only means of creating them."*

We apprehend that the farmers of the United States are not, generally speaking, any more solicitous to turn the urine of their cattle to account for manure, than those of Nova Scotia. There are some cultivators, however, who have taken measures to secure this substance, and to apply it to useful purposes. Mr. Robert Smith, of Baltimore, has his stables constructed in such a manner that all the liquid discharges of his cattle are conducted, together with the wash of the barn-yard into a cistern, pumped into a hogshead and applied in a liquid state to the soil which it is wished to manure. This mode of making use of this substance is likewise recommended in the *Code of Agriculture* as follows:—"The advantages of irrigating grass lands with cow urine almost exceed belief. Mr. Harley, of Glasgow (who keeps a large dairy in that town,) by using cow urine, cuts some small fields of grass six times, and the average of each cutting is fifteen inches in length. There are disadvantages, however, attending this mode of applying this powerful manure. It must be applied soon after it is formed, or oftentimes the putrefactive process will commence, and deprive it of a part of its efficacy. And as urine is of a scorching quality, it is

* *Letters of Agricola*.

† See N. E. Farmer, No. 6, p. 44.

to apply it to growing crops in great heat or
ht. Hence it is inadvisable to use it, except for
after the month of April or May, unless diluted.
particularly useful in the spring, when the appli-
of liquid manure gives a new impetus to the
and makes its growth more vigorous. This ma-
forces newly planted cabbages in a most remark-
nanner."

It is true that more manure can be obtained from
ale of cattle than from their dung and litter, in
proportion of 7 to 6 (as would seem by Mr. Alex-
's experiments as above detailed) and that by our
on modes of husbandry this stale is nearly or
squandered away, the discovery is of very great
tance indeed to agriculture. It is nothing less
a method by which farmers may, with a small
use, somewhat more than double their usual quan-
stable manure. And if farmers should "value
re as a miser does his strong box—should grasp
and hoard it as eagerly and anxiously as a cove-
nan accumulates treasure,"* surely the wise cul-
tor will not grudge some labor and expense to ac-
more than double the usual quantity of so valua-
an article. It is very true there are many things
taken into consideration in all these economical
sses. A principal inquiry should ever be whether
aving will cost more than the benefit arising from
be worth. Many improvements, which are high-
luable in old and populous countries, where labor
cap and land dear, cannot be advantageously
ed in this country, where the object, in general,
her to make the most of our labor than of our
It is to be recollected, likewise, that in New
nd, during a considerable part of the time in
a cattle are usually housed, the liquid manure is
converted into ice, and, in that state, must be
ferred to the dung-heap, or inconvenient accumu-
s will take place before a thaw would render it
icable to separate the liquid from the solid parts
manure. Still, with all these disadvantages, we
re, in most cases, it is highly advisable to preserve
iquid portion of stable manure separate from the
part; especially where cattle are soiled, or horses
d during all or the greater part of the year. In
ext number, on the subject of these essays, we
se to state some means by which such separation
preservation may be conveniently and economi-
effected.

These expressions, we believe, belong to the Hon.
Peters, of Pennsylvania, but we do not recollect
we found them.

(TO BE CONTINUED.)

stake Corrected.—In our paper of Dec. 28, p. 174,
article headed "Satellites of Venus," which is
tributed to the Buffalo Patriot of 26th Nov. This we

h newspaper above a year ago. We are moreover
l that the magnifying power, which that article
as the property of the common mirror, does not
x, but that a mirror will sometimes reflect double or
triple images of objects. This circumstance led the
Jautta gentleman to suppose that the planet Venus
accompanied with satellites, when for any thing
now to the contrary, her ladyship is as destitute
f attendants as a belle of the last century, whose
ons have long since faded into non-entity.

FARMER SUMMARY OF NEWS.

CONGRESS exhibits appearances of industry, and
he is every indication of the session's being less
lively, not so windy, and more efficient than some pre-
cious ones. Mr. Cannon has shewn himself to be a
go piece of ordnance by sundry reports, which we
na not calibre sufficient to repeat. They relate, how-
er, to improving the Militia of the U. States—Of in-

quiring into the expediency of continuing the prefer-
ence given to West Point Cadets in entering the public
service over those of Partridge's Academy and others—
Of employing the regular army in building fortifications
—A statement of the duties performed by navy officers,
&c. A bill has been reported for allowing the mother
and sister of the late Wm. H. Allen, \$150 per annum
each, for five years.—Resolutions have passed both
Houses for inquiring into the present state of the trade
and intercourse between the U. States and the Island
of Hayti, and report what measures would be neces-
sary to improve the commerce of both countries.—Mr.
Taylor, of N. York, has moved a resolution, That the
Committee on the Judiciary be instructed to inquire
into the expediency of allowing costs in all cases where
damages may be recovered for the violation of the
rights of patentees, under the several acts concerning
the issuing of patents for useful discoveries and inven-
tions.

FOREIGN.—An arrival at New York from Havre,
brought Paris papers to the 19th November, containing
the latest advices from Europe. By them we learn that
the Congress at Verona held their first business session
on the last day of October. The assembly deliberates
with closed doors, and of course, nothing to be depend-
ed upon, can be gathered respecting their proceedings.
With regard to Greece, the accounts look encouraging.
Letters from Trieste, [no date given] inform that a
large body of Greek troops had penetrated from Liva-
dia to the southern part of Thessaly, where they at-
tacked and entirely defeated the forces of Chourschid
Pacha, collected there—details not received. The
Turkish fleet which suffered so severely in the Morea,
had finally arrived in the Dardanelles, and its distress-
ed condition had spread dismay throughout the whole
city. It is said, likewise, that the Greeks had gained
great advantages over the Turks in Candia.

A rumor has been issued by the Turkish government,
prohibiting the use of furs, gold lace, cashmere shawls,
&c. which has excited much agitation in Constantinople;
and the English merchants there, were seriously
affected by its operation.

A Vienna article, dated Nov. 2, states, on the author-
ity of letters from Verona, that the Ministers of the five
powers there, have unanimously voted to disapprove of
the progress of events in Spain, and that the interests
of Europe will not allow them to remain as they are.
This is to be formally and officially notified to the
Cortes by a manifesto. Should they refuse to listen to
this memorial, the ulterior measures of the Cortes will
be looked for with anxiety. And it is said that the only
answer which the Cortes will give to any Manifesto
from the Congress at Verona, will be a decree to raise
an additional army of 100,000.

A Paris paper says "it is believed that Russia, Aus-
tria and Prussia are determined to extinguish every
spark of revolution." The French government, how-
ever, says a London paper, are determined to abide by
the decision of England, in regard to Spain.

The Caledonian Canal, in Scotland, which opens a
communication between the eastern and western seas,
was opened the latter part of October. It is nearly 20
years since it was commenced, and it cost 900,000*l*.

Three bottles of green Gooseberries were lately acci-
dentally dug up in England. They were in excellent
preservation, although it is thought they had been buried
a century or more. So says an English paper.—
Might it not be well to try some experiments suggested
by this fact?

DOMESTIC.—An ingenious mechanic in Philadel-
phia, has invented a new safety lock, to which he has
given the name of *Patent Trap Lock*. It is contrived
so that any key but its own being introduced into the
lock, is made fast, and cannot be removed. The con-
struction is simple, yet if five hundred locks were made,
no key would fit any other than the one for which it
was intended.

Counterfeit three dollar bills of the Eagle Bank of
New Haven are in circulation in New York. They are
intended to imitate those of the letter C, and are made
payable to J. Ingersoll, dated Dec. 1st, 1818. The
imitation is said to be very good, and well calculated
to deceive.

A meeting of Printers and Booksellers of Philadelphia,
has been called to choose a person to attend the four
hundredth grand anniversary of the invention of the Art
of Printing, to be celebrated at Haerlem, in Holland,
in 1823.

The Hon. James Lloyd has been elected a Senator
in Congress for six years from 4th March next.

The Hartford Brewing Company offer a premium of
twenty dollars, or a silver cup, or any other plate of
that value to the Farmer who shall raise, sell, and deliv-
er to the said Company, at their Brewery in that city,
the best lot of Barley, the growth of the ensuing season,
not less in quantity than one hundred bushels, being
the produce of one farm—the quality of the barley to
be ascertained by the weight of it.—For the next best
lot of one hundred bushels, on the same terms, they
will give a premium of ten dollars, in addition (in both
cases) to the current price of barley. The barley to be
delivered before the first day of January, 1824, on which
day the premiums will be declared and paid. This no-
tice is signed by Lorenzo Bull, agent.

On the 1st inst. during the snow storm, a barn was
burnt at Hebron, Con. belonging to Mr. Daniel White,
of that place—supposed to be the work of an incendiary.
A horse, wagon, and a considerable quantity of
grain were thus destroyed.

Ripe cherries were gathered near Norfolk, on the
4th of December last.

Miss Ann Robins, aged 22 years, was lately drowned
in the river, opposite Middletown, in Connecticut. A
number of young persons went to the river for the pur-
pose of sliding; the deceased, with another lady, and
two young gentlemen ventured on the ice, when she,
with one of the gentlemen, slid within four or five feet
of the glade, before they perceived it; but they were
moving with so much rapidity as to be unable to check
themselves, and plunged into the water. She had hold
of the gentleman's arm, when they went in, but im-
mediately released her grasp; he turned round and
took her by the arm; she then got hold of the ice but
it gave way; he continued supporting her till his feet
becoming entangled in his cloak, he could support her
no longer. He succeeded in getting hold of the ice,
and was saved, but was unable to stand when taken
out of the water.

The paper-mill of Gen. L. Burbank, in Fitchburgh,
with its contents, was destroyed by fire on the 2d inst.

BROWN'S PATENT VERTICAL FAMILY SPINNER.

FOR SALE, at the Agricultural Warehouse, in
Chambers No. 20, Merchant's Row, (opposite
the East end of the Old Market)—a number of

Brown's Patent Family Wool Spinners,

which are found on trial to be one of the most useful
domestic implements that have ever been invented for
that purpose, being of so simple and easy construction
that a girl of the age of 15 can well do the work of six
persons in spinning, and so compact in its form as not
to require so much space as a common family spinning
wheel. The advantage of this machine over and above
the common mode of family spinning, is at once tested
in a few minutes' operation with the machine; it at
once discovers its immense saving of labor, its accuracy
in spinning a good thread, and the quantity it will
spin. It requires no further examination to judge of
its utility than to see it operate. It is afforded at so
low a price as to bring it in common use to every prac-
tical farmer, and is well calculated for the employment
of the inmates of our common town's poor houses.—
Any number of Machines can be furnished at the short-
est notice, and warranted. Jan. 31

FOR THE NEW ENGLAND FARMER.

From Silliman's Journal of Science.

*The Pig and the Connoisseurs; or Nature out-acted.
An Apologue for Critics.*

[Altered from SMART, a British Poet.]

A wealthy cit, the other day,
Having a notion for display,
Built him a large, commodious stage
To show the mirror of the age,
Invited all of Thespian fame
All critics too of any name,
The chiefs and followers of the ton
For actors, or for lookers-on.
To this assemblage with the rest
There came a genius who profess'd
To have a curious trick in store
To set an audience in a roar.
Throughout the city this got air,
And every body came to stare.
The actor soon his entry made
With neither prompter nor parade—
'Twas all attention, all suspense,
And silence gagg'd the audience.
He hid his head behind his wig,
And with such truth took off a pig.
All swore 'twas serious and no joke,
And doubtless underneath his cloak
The man had hid a grunting elf,
Or was a real hog himself.
A search was made, no pig was found,
With thundering claps the walls resound—
Box, pit and galleries jointly roar,
"O rare! O brave! encore! encore!"
Old Roger Grouse, a country clown,
Who yet knew something of the town,
And like some other countrymen
Would have his notions now and then.
Thought it not fair that our metropolis
Such genuine humor should monopolize—
Beheld the mimic, and his whim,
And on the morrow challeng'd him,
Declar'd 'twas true, as scale of Gunter,
He could out-grunt the famous Grunter.
The trial came, but each spectator
Was prejudic'd, and rank ill nature
Usurp'd the minds of men and wenches.
All came to hiss, and break the benches.
The mimic took his usual station,
And squeak'd to general approbation.
Again "encore! encore!" they cry,
"This beats the Old Nick, high and dry."
But Hodge conceal'd, amid the racket,
A real pig beneath his jacket—
Then forth he came, and with his nail
Pinch'd the poor noisy urchin's tail.
The tortur'd pig, from vocal throat
Pour'd forth the natural swinish note;
Fit, box and gallery bawl'd "egad,
"Sure never stuff was half so bad,
"Was never actor made a greater
"Departure from the line of nature—
"That like a pig?" each cried in scoff,
"Pshaw! non-sense! bockhead! off! off! off!"
The mimic was extoll'd, but Grouse
Was hiss'd and hustled from the house.
"Hearken—one word before I go,"
Cried honest Grouse, and stooping low
Produc'd the pig, and thus aloud
Address'd the stupid, partial crowd:
"Behold and learn from this poor creature,
"How much you critics know of nature;
"Fools will be fools in spite of art,
"While nature acts a natural part."

LEGHORN HATS.

On the Material and Manufacture of the Italian Bonnets, and the Habits and State of Society of the Manufacturers.

Chateauvieux, in his agreeable and instructive letters, written from Italy, to Pictet, in 1812 and 1813, describes the persons who manufacture the Tuscan bonnets, and their state of society. In his sixth letter, which is dated at Florence, are the following observations:

"The road I travelled, was bordered on both sides with village houses, whose distance from each other did not exceed one hundred paces. They are all built of brick; and the architect has bestowed upon them a justness of proportion, and an elegance of form, unknown in our climates. They consist of a single pavilion, that has often but one door and two windows in front. These houses are always situated along the road, and separated from it by a terrace and supporting wall, some feet in breadth. Upon this wall usually stand several vases of the antique shape, containing aloe plants, flowers and young orange trees. The house itself is entirely covered with vine branches; so that, during summer, one knows not whether they are so many pavilions of verdure, or dwellings prepared for winter.

"In the front of these houses, swarms of young country girls are seen, dressed in white linen, with corsets of silk, and straw hats, adorned with flowers, inclining to one side of the head. They are constantly occupied in braiding the fine plait, the treasures of this valley, from which the straw hats of Florence are made.

"This branch of industry has become the source of the prosperity of the valley of the Arno. It produces, yearly, three millions of livres; which are distributed exclusively among the women; for the men never engage in this occupation. Each young girl buys for a few pence the straw she wants: she then exerts her skill to braid it as fine as possible; and she herself sells, and for her own profit, the hats she has prepared. The money she thus earns constitutes her portion. The father of the family has nevertheless the right to require of the women belonging to his house, a certain amount of rustic labor on the farm. He receives this labor from the females of the mountains (the Appenines,) whom the girls of the plains pay, out of the produce of their hats, for performing the task in their stead. One of them can earn from thirty to forty sous a day in braiding her straw, while she can hire a poor Appenine woman to do her field labor for eight or ten; and they secure, by this commutation of service, the delicacy and flexibility of their fingers necessary for their nice and fine work, and which would be spoiled by such exercises as harden and stiffen the hands.

"Such, Sir, are the female peasants of the vale of the Arno; whose grace and beauty are so celebrated by travellers; whose language, Alfieri went there to study; and who seem, in fact, born to embellish the arts, and to furnish them models. They are shepherdesses of Arcadia, but they are not peasants—they possess only the health and freedom from care of that state, and never know its anxieties, its sun-burnings, and its fatigues.

"I have been informed, that a crop of acres is sufficient for all the straw of the manufacture of Tuscany. This straw is a product of a headless wheat, harvested before it is quite ripe, and whose vegetation is weakened by the sterility of the soil. This is selected among the calcareous hills; it is never manured, and the seed is sown very thick. These habitations, so near to each other, show of themselves that the domains to which they belong are very limited, and that property is remarkably subdivided in these valleys. In fact, the extent of these little plantations is often from three to ten acres. They lie around the dwelling, and separated into lots by small canals and rows of trees. These trees are sometimes mulberries, almost always poplars, whose leaves serve to feed their animals. Each of them sustains a vine, whose branches the cultivator twines in a thousand directions.

"These lots laid out in long squares, are extensive enough to be cultivated by a plough without wheels drawn by two oxen. There is one pair of these creatures among ten or dozen of these tenants; and they are employed in succession, for working all the farms in connexion. These oxen came from the state of Rome and Maremmes; they are of the Hungarian breed, and are exceedingly well kept, being covered with white clothes, decorated with a great deal of embroidery, and with set tassels.

"Most of these land laborers keep a horse of a fine and elegant form. He is harnessed to a small two wheeled cart, neatly constructed, and painted red. It serves for all the purposes of transportation on the farm, and more especially to convey the good man's daughters to the market and the ball. Accordingly, on holidays, the roads are filled with hundreds of these little carts, moving in all directions, and carrying young girls, adorned with flowers and ribbons.

"The farms of the valley of the Arno have not forage enough to support cows: the cultivators, therefore, feed heifers only. They buy at the age of three months, and keep them until eighteen, when they are sold to the butcher, and young ones bought in their place from the pastures of Maremmes that the drovers bring the heifers to the fair in the valley of Arno.

"You will comprehend the motive for this practice, when I shall have explained to you the feeding systems adopted in these valleys. There is no natural meadow. The leaves of the tree, the trash of the legumes, and a little clover are the only feed for the animals. In this country, every thing is reserved for men, whose numbers have augmented beyond measure, under the most ancient civilization, &c. &c.

The plant it will be remembered, of which the finest Leghorn bonnets are made, is a white variety of the summer and winter wheat of the Arno.

Consellor Littienstern, of Frankfort on the Maine, has published a very singular work, which he attempts to prove, argumentatively and methodically, that the predictions respecting Anti Christ are now on the eve of being accomplished. Anti Christ, he asserts, will appear in 1823; his arrival will be succeeded by ten years religious wars; after which the Millennium, as he assures us, will commence in 1836!

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

VOL. I. BOSTON, SATURDAY, JANUARY 18, 1823.

No. 25.

DISEASES OF CATTLE.

LECTED AND COMPILED FROM THE BEST AUTHORS,
BY THE EDITOR.

Fog Sickness, Hoven, or Blown.

"We come now to treat of a class of diseases all more important, with respect to horned cattle, than the foregoing; that is, obstruction, or imperfect action, in the organs subservient to digestion. Under this head will be brought Fog Sickness, Hoven, or Blown; Gripes, or Flatulent Colic; Indigestion, loss of the Cud; and Rindice, or Yellows. These diseases, however, will be better understood, if we give, in the first place, a short description of the cow's stomach. All animals, which ruminate, have more than one stomach; in the cow there are four; the first is considerably larger than the rest, lies on the left side, and is commonly called the paunch. The food, having been sufficiently macerated in this stomach, is forced up gradually into the mouth, where it undergoes a complete mastication, which is termed chewing the cud. The food is then again swallowed, and conveyed to the second stomach, for the gullet opens indifferently into both. It ends exactly where the two stomachs meet; and there is a smooth gutter, with rising edges, which leads into the second stomach, and thence to the third and fourth: the animal, however, has the power to direct it into which it will. The second stomach is named the *bonnet*, or *ing's hood*. Its internal surface consists of cells, resembling a honey-comb; where the food undergoes a farther maceration, and is then conveyed to the third stomach, called *manplies*; because the internal surface rises up into many folds. Some of those folds are longer than others, and on their surface small glands may be seen, something like millet seed. From this it passes into the fourth, or red stomach, commonly called the *caul*. This much resembles the human stomach, or that of the dog; only the inner folds are longer and looser. Here the food is perfectly digested, and prepared for the nourishment of the animal.

"When cows or sheep are turned into a fresh pasture, of a different kind from that they had been accustomed to, they sometimes eat so greedily, that the stomach is incapable of contracting, or forcing back its contents into the mouth. When this happens, the food undergoes a kind of fermentation, in consequence of which a great deal of air is generated, and the paunch so excessively extended, that, if the animal is not relieved, it will either burst or destroy him by suffocation. An instrument has been invented by Mr. Eager, for giving vent to the confined air, which is very simple and appears to have answered the purpose completely. It consists of a cane six feet in length, with a round knob of wood, perfectly secured at one end. An assistant is to lay hold of the cow's horn with one hand, and the part which divides the nostrils with the other. The operator is to take the tongue in his left hand, and with his right he is to force the instrument down the gullet. As soon as it enters the paunch a great deal of air will rush out. The instrument may

remain in the stomach, without injuring the animal, until the air is perfectly evacuated.

"It sometimes happens, that the distention of the paunch takes place so suddenly, and in so dangerous a degree, that no time is allowed for using the instrument; in this case a sharp pointed pen-knife may be plunged into the paunch through the skin, by which the confined air will immediately escape. There is no difficulty or danger in the operation; nor is any other instrument required than a sharp pointed pen-knife. Should the opening be plugged up with the contents of the paunch, they may be removed, or the orifice kept open with a probe or feather. When all the air has escaped, let the wound be closed with any kind of sticking plaster, or pitch. This opening is to be made on the left side, between the haunch bone, and the last rib."—*White's Treatise*.

Clayton, an English writer on Farriery, directs this last mentioned operation to be performed in the following manner.

"Take a sharp pen-knife and gently introduce it into the paunch, between the haunch bone and the last rib on the left side. This will instantly give vent to a large quantity of fetid air; a small tube of a sufficient length may then be introduced into the wound,* and remain there until the air is sufficiently evacuated; afterwards take out the tube, and lay a pitch plaster over the orifice. Wounds of this kind are seldom attended with danger; when it has arisen, it has been occasioned by the injudicious operator introducing his knife into the wrong part. After the wind is expelled, and the body has been reduced to its natural state, let a cordial drench be given."

Dr. Monro, Professor of Anatomy at Edinburgh, invented an instrument, which was intended to answer the same purpose with the invention of Mr. Eager, above mentioned. It consists of iron wire about one sixteenth of an inch in diameter, twisted round a rod three eighths of an inch in diameter, and made of polished iron, in order to give it a cylindrical form; the wire, after being taken off the rod should be covered with smooth leather. To the end of the tube, which is intended to be passed into the stomach, a brass pipe two inches long of the same size, or rather bigger than the tube, is to be firmly connected; and to prevent the tube from bending too much within the mouth, or gullet, an iron wire, one eighth of an inch in diameter, and of the same length as the tube, is put within, but afterwards withdrawn, when the tube has entered the stomach. As Dr. Monro has ascertained that the distance from the fore teeth to the bottom of the first stomach of a large ox, is about six feet, the tube ought to be at least two yards long, that it may operate effectually in the largest oxen. When the instrument has been introduced into the stomach, it may remain there for any length of time, as it does not obstruct the respiration of the animal: the greater part of the condensed air will be speedily discharged thro' the tube;

* This may be of elder, sumach, or a turkey, or goose quill

and should any ardent spirits, or other liquor calculated to check the fermentation, be deemed necessary, it may be safely injected through this pipe. In short, the flexible tube here described, has been found of infinite service in saving the lives of cattle and especially of sheep, when subject to similar disorders, or any other swelling peculiar to those creatures."

The 33d vol. of Mr. Young's *Annals of Agriculture*, announces the following recipe as a specific for this disease, even in the most desperate cases; effecting a cure within the short space of half an hour. Take three quarters of a pint of olive oil, and one pint of melted butter or hog's lard; give this mixture by means of a horn or bottle; and if it does not produce a favorable change in a quarter of an hour, repeat the same quantity and walk the animal gently about. For sheep attacked with this malady, the dose is from a wine glass and an half to two glasses.

The following simple remedy we have been told is effectual, but cannot say to what extent it may be relied on. Make about a pint of lie, either with hot embers thrown into a sufficient quantity of water, or by dissolving therein about an ounce of pot or pearl ash, and turn it down the throat of the ox or cow affected. A proportionably less quantity is said to answer for a sheep. This medicine, we are informed, operates by neutralizing and absorbing the carbonic acid gas in the stomach of the creature, which causes the swelling and other symptoms to subside. We wish this remedy might be tried, and its results made public. We suspect, however, that in extreme cases, it will be necessary either to make an incision, or make use of Dr. Munro's flexible tube, or Mr. Eager's cane with a knob of wood at its end. Where the danger, however, does not appear to be imminent, there is little doubt but that either the oil and lard, or the lie, as mentioned above, would prove effectual.

When the animal has obtained relief by the means mentioned above, one of the following drinks is by Dr. White recommended to be given.

No. 1.

Powdered ginger,	1 oz.
Spirit of nitrous ether,	2 oz.
Oil of peppermint,	30 drops.
Warm water,	1 pint.

(Mix for one dose.)

No. 2.

Powdered caraway,	1 oz.
Ginger,	1 dr.
Warm ale, [or warm water,]	1 pint.

(Mix.)

No. 3.

Powdered gentian,	1 oz.
Cascarilla bark,	2 dr.
Warm ale, [or water,]	1 pint.

(Mix.)

An infusion of camomile flowers and ginger is also a good stomachic in such cases.

When cattle have suffered a severe attack of this disease, the stomach is generally weakened by it; great care, therefore, is necessary, in or

* See Domestic Encyclopedia, Art. Cattle

der to prevent a return. For several days after, they should be fed rather sparingly, or not be allowed to eat much at one time; and every morning and evening, for three or four days, may take one of the above drenches.

Sheep are liable to a similar disease, and may be relieved by the same remedies. The instrument, however, employed for sheep, need not be more than three feet in length; it should also be smaller and more flexible. It has been said that a common cart whip, may, on emergencies, be made to answer the purpose, if used with dexterity.

Any one, unaccustomed to handle cattle, would find some difficulty in using Mr. Eager's instrument; but if the horn be held firmly with the left hand, and the part which divides the nostrils be grasped firmly with the right hand, the animal will generally submit quietly to the operator.

(TO BE CONTINUED.)

Although we do not fully concur with the author of the following Address in all the opinions it contains, we fully appreciate its general merits, and are therefore pleased with an opportunity of giving it a place in our paper. We have taken the liberty to attach a few notes to such passages as do not fully coincide with our own ideas. We would not, however, be tenacious of our sentiments, unless founded on truth, and will readily retract them if shewn to be erroneous.

ADDRESS, delivered before the Ontario, (N. Y.) Agricultural Society, at its fourth Annual Meeting, October 22, 1822. By THOMAS D. BURNALL, Esq.

Gentlemen of the Agricultural Society,

In addressing the present assembly, almost every member of which is probably as well acquainted with the details of agriculture as myself, I can hardly hope to offer much matter that will prove interesting from its importance, or pleasing from its novelty.

We live in an age in which every field of useful knowledge is eagerly and successfully explored; and in a country, throughout which the means of correct information are as free and extensive as the air we breathe.

A spirit of inquiry has gone abroad, through every department of science; and, what may perhaps be justly claimed as distinguishing and elevating the present age above former times, is the fact, that the lights of science, and the laborious investigations of learning, have been called to the aid of useful arts, and no longer waste their strength in toiling through metaphysical disquisitions without end, or the discovery of truths that can have no practical use.

Learning is no more subject to monopoly, but is actively engaged in the service of the arts; and what has heretofore been claimed as the privilege of sects at schools, is now the property of the community, for the benefit of all.

Agriculture, which had long been degraded from its just place in the scale of human occupations, has assumed its proper rank in public estimation, and the name of "Farmer" has ceased to convey to the mind any idea of boorish inferiority or servile dependence.

Agriculture is no longer a plodding art, in which we blindly persevere in inveterate hab-

its, for no better reason than that our fathers have pursued them before us; but has become an interesting science, in which all the powers of the human mind have been called into action, and all the various resources of mechanical power have been put in requisition to aid its progress.

The advance of knowledge has been bold, rapid, decisive. Improvements have been introduced, that leave us to wonder how so many centuries should have rolled away without their discovery and practical application.

All this has been effected, not by chance or accident, but the mighty force of the human mind, steadily directed in pursuit of truth, guided and governed by reason and observation.

Chemistry, botany, mineralogy, and the principles of mechanical power are no longer the sources of useless experiment to the philosopher and scholar, but are pressed into the active service of Agriculture and Manufactures—and in short, every branch of science is rendered subservient to the supply of our wants, and the gratification of a refined taste.

One cause of this rapid increase of useful knowledge, has been the practice universally adopted, of following boldly the evidence of experiment, wherever it may lead, rejecting theory on mere authority, and especially of reasoning from facts to general principles.

The want of this habit of correct investigation, and of arranging and systematizing our ideas, often perverts and defeats our best endeavors in the pursuit of knowledge; and it is to this point that I wish, at present, to direct your attention; and though I should fail to present any new facts to your observation, yet should I convince you of the utility of establishing general principles, and of applying them to every thing connected with your pursuits and occupations, I shall not deem my labor altogether vain.

In glancing our eyes over the mass of matter already accumulated for the improvement of Agriculture, we feel, not so much the want of materials, as of skill to select and apply them to advantage.

Facts and experiments have been so abundantly multiplied upon us, that the field of agriculture is completely overrun by them, and the plain practical farmer, although abundantly supplied with the means of improvement, is still at a loss how to use them to advantage. Within the last few years particularly, since agriculture may be said to have become fashionable, new experiments are so eagerly pursued, that it may be well to pause a moment, and while delighted with the novelties of the day, to profit by the idea before suggested, of searching for evidence, and rejecting authority. In doing this, we shall find much to approve and adopt, and very much to discard, as erroneous or useless. And here I would be understood not as answering or disapproving the efforts that are making to advance the agricultural interest. In every art, a great proportion of experiments must necessarily prove unsuccessful; but it is the part of wisdom still to profit by them, for even an unsuccessful experiment may at least furnish the basis of improvement in more skilful hands, and thus often lead to some unexpected and satisfactory result. But I would suggest to those whom I have the honor to address, while engaging in new

schemes of improvement, the importance establishing in our minds some fixed principle of testing such facts and experiments as are presented to our observation. And here it may be well to remark, that agricultural experiments are subject to many variations and errors, which must not be overlooked in forming an opinion.

In the first place, much depends on the care and accuracy of the experimenter, in every science. But in addition to this, experiments in vegetable economy are subject to all the accidental changes and variations of the seasons—untimely droughts, excessive rains, &c. beside such mistakes as occur from the difficulty of distinguishing the difference of soils, &c.; but what demands peculiar care in receiving foreign experiments, is that we are exceedingly liable to errors arising from the different character of soil and climate, which may essentially vary the result of a particular experiment in mode of husbandry. Hence arises the necessity that the practical farmer should scrutinize facts closely, reason clearly, and reject authority boldly, unless supported by repeated and satisfactory experiment. These principles, combined with patient industry in their practical application to our farms, contain the element of that promethean fire, which can warm and quicken the cold and inanimate earth into life and action. In the character of the American farmer, accurate observation, and close industrious discrimination in experiment, are more wanting, at present, than ingenuity in inventing, or boldness in adopting theories.

In the paths of science as of life, the careless traveller may range delighted through the universe; and still return as ignorant as he went but to him who observes attentively, and digest and arranges his observations closely and methodically, every step adds new interest to his inquiries, and furnishes fresh food for his mind. With a keen and observant eye he examines each object, profits by the skill of others, and improves each discovery to some useful purpose. But in roving abroad for new sources of profit, we should never overlook or neglect those already in possession.

The flow of knowledge has been so rapid that we seem at times, in our eagerness for improvement, to have almost lost sight of many of those landmarks that are necessary to our security. I would not in the least check a spirit of inquiry in my countrymen, but would only refer to the proper means to render that spirit efficient and profitable. To this end, I would recommend the practice of often examining our own grounds, for the purpose of ascertaining their soils, situations and capabilities of improvement; to search for causes of failure or success in our various experiments, and above all, to form a general plan of operations, which may never be lost sight of in the eager pursuit of novelties.

In doing this, it is useless to confine ourselves with speculative disquisitions, or refined theories on the processes of vegetation—to inquire, for instance, how plants grow, whether they are nourished by the earth, the atmosphere, or both—it is sufficient for our purpose that they do grow, and their health may be promoted by our care, or destroyed by our neglect—Whether smut in wheat springs from disease or insect, or a parasitic plant—Whether plaster acts by being calcined and then imbibed as nourishment;

merely by its attractive properties on the atmosphere—Whether certain applications to the trunks of our fruit trees afford nourishment to the bark, or act mechanically as a shield to protect it from the attack of its enemies—are of less importance, than to know what is necessary, in each case, to produce the desired effect. These questions form subjects of inquiry to the curious and attentive observer, and are more or less important; but should serve rather as pleasing sources of amusement and relaxation during the hours of leisure, than as claiming our labor or care.

And here permit me to explain my ideas more fully, by a few plain practical rules and observations:

1st. Every farmer should form to himself a *general plan of husbandry*, to be pursued on his farm.

To do this to advantage, let him regard attentively his grounds as to soil and situation—let him ask to what are they best adapted—ploughing or grazing, or are they fit for both? What is my supply of labor and money, and how are they to be rendered the most productive?—Where is my market, what articles command the best price and readiest sale, in proportion to the expense of raising them?

2d. Having chosen your course generally, see that your buildings and grounds are arranged in the most convenient manner for your purpose; & in our lovely and fertile country we may justly be reproached for want of taste, if we do not generally give our fields a pleasing and regular appearance, as this not only adds to the beauty of the farm, but also saves labor and materials. And we may remark, that small fields are most profitable, especially for grazing. For pasture, twenty acres, divided into three fields, and pastured in rotation about ten days or a fortnight at a time, may be considered equal to thirty, if kept one, by the relief the parts afford each other. Look to your fences—see that they are good and substantial. Without this, you may consider yourself at best, but as a joint tenant with all the marauding flocks and herds in the neighborhood. Let your fences then, especially the better ones, be sufficiently high and strong to resist not only your own cattle, but also those that rest the highway, and live by plunder.

In apportioning your grounds, do not forget to reserve an abundance of your best timber for fuel, fences and other purposes. To many, this may seem a needless caution, while so large a portion of the country is covered with wood;—but I have no doubt there are some who hear of it, who have reason already to regret their wanton destruction of this necessary article. I know it is perfectly natural, on entering our new lands, to feel that there never can occur a want on this head; but it is astonishing to mark how fast these forests disappear before the axe of the woodsman. Estimate then the amount necessary for your use, and a perpetual supply to the farm, and be sure rather to overrate than to undervalue the least to fall short in your estimate.

3d. In trying new experiments, or making improvements, still keep your *general plan* in view—try nothing but what will be profitable to yourself if successful, and nothing *inconsistent* with your other pursuits. Whatever you attempt, do it thoroughly and accurately—be sure of your *facts*, for false premises necessarily lead

to wrong conclusions. Above all, let your work be done in season. The best tillage is but labor lost, unless bestowed in time to render it productive; and I remark upon this because it is too generally neglected. We often put off our work until the moment is past to render it profitable, and are then driven in our haste to do it imperfectly and unprofitably. This is particularly the case with our fall sowing; or rather we feel the pernicious effect most in this, because it is our most important operation. Generally speaking, early sowing is advisable in our country, where none of those objections, which operate against it in old countries, exist to any great degree. Rye, if sown early, yields an abundance of excellent pasture, sufficient in fact to pay the whole expense of cultivation, and may be fed down without the least injury to the crop, in the spring when it is most needed.

4th. Endeavor, as far as practicable, to remedy physical defects, such for instance, as the want of water, by leading in streams, or digging wells—superfluous moisture, by draining, &c.—want of materials for fences, by planting trees or hedges.

Remove loose stumps, stones, logs and other obstructions that impede the plough, and render the cultivation imperfect, and of course unprofitable; for remember that a field half tilled is better left alone. Never starve your stock or your farm from a desire to save too much. Furnish to your teams and stock of every kind an abundance of generous food, to your farms a supply of manure, and they will soon repay you with interest—much is lost by ill-timed economy—never spoil a crop to save expense—whatever should be done, is worth being well done.

But here it may be asked, what is meant by good cultivation, and when is the farmer to think his work well done? I answer generally, our work is well done, when our lands are cultivated in a way to give the *greatest amount of produce at the least expense of forming capital*.—And *farming capital expended*, consists in the yearly value of the land, and the labor and money expended in its cultivation; hence no particular amount of culture can be called good husbandry, but in reference to the relative value of land and labor: for as the price of land is higher or lower in proportion to that of labor, so must the degree of culture be varied in order to render it more productive.

Thus, in Great Britain, where land is dear and labor cheap, much labor should be applied to little land, as the land is in this case the principal part of the capital; and for the same reason a course of farming may be profitably pursued there, which requires much labor in its prosecution. Here, the case is reversed, and of course, we should apply our labor to more land, and should adopt that style of farming, in which most land may be well cultivated with the least labor, as with us the labor is the most expensive part of our farming capital—thus, for instance, if the rent of an acre of land is worth two dollars, and by expending six dollars in cultivating it, we produce twenty bushels of wheat, then the capital expended would be eight dollars, giving a return of two and a half bushels for each dollar expended. Again, if we expend double the former amount on the same acre, then the capital expended would be fourteen dollars, and we ought to receive in return thirty-five

bushels, in order to render our capital as productive as in the first case. Hence the importance of reasoning clearly and boldly on the subject, without regard to authority, as every thing depends on the judicious application of general principles to the concerns of our farms.

When we see high cultivation succeed abroad, we should inquire how far the circumstances that render it good husbandry there, are varied with us, or whether the same mode could be rendered profitable here, since the work that is well done here, might be very imperfect husbandry in England or Flanders, and utterly ruinous in China.

It is certainly pleasing to see fine crops and perfect culture; but this alone does not constitute good husbandry. If fifty bushels of grain can be raised at a less expense of capital from two acres than from one, then we are losers by attempting to force them from one. We have in our country more land than labor; that is, we have more land than can be cultivated perfectly. Of course, then, we want to apportion and apply our labor to our land in a way to render both most productive, and he must be pronounced the best farmer who does this most judiciously, rather than he who produces the greatest number of bushels from an acre by inordinate means.

From the preceding remarks, it would appear, that grazing should be encouraged among us, in preference to ploughing, as in that way most land may be well cultivated by a given amount of labor; and I might also draw another powerful argument to prove that it is too much neglected, from the fact, that while it costs, on an average, one half of the value of grain to transport it to market, cattle, horses, sheep and swine may be taken there for one tenth, and fine wool for one fiftieth part of their value.*

* These observations do not apply to farmers who live in the neighborhood of a good market; and perhaps the rule "that grazing should be encouraged among us in preference to ploughing," cannot correctly be applied to the country at large. If wheat can be imported from Great Britain, and sold in New York for a profit of 25 per cent. as we are told it has been, we should encourage the growth of that, if no other arable product. We believe that what is called the *convertible system* of husbandry, where a proportion of a farm is cultivated for grain and roots, and a part employed in raising grass for pasture and mowing, &c. is, in general, to be preferred. Exceptions to this rule, are, however, of continual occurrence. Straw is one of the products of arable land, which is very useful where a stock of cattle is kept, if not for food, at least for litter, and to imbibe and retain the strength and richness of the liquid part of the manure. If the preference is long given to any one branch of husbandry, (such as ploughing or grazing) that branch is at length rendered scarce worth pursuing by too many competitors for its profits, and some despised and neglected branch is taken up to greater advantage. A farmer, therefore, will, in general, do well to raise as great a variety of necessary articles as his soil, means of culture, climate, &c. will admit, that he may be able to meet every fluctuation of market, as well as supply his own wants. In other words, he should have something of every thing for sale, and but little of any thing to buy. But even this good general rule may be liable to many exceptions. A farm may be very moist and good for nothing but grass. It is then folly to plough it. It may be dry, and fit for no grass but clover. In

In order then to direct our labor aright, we should accustom ourselves to calculate the expense of raising a given amount of each article of produce—to ask for instance, how much capital, viz. how much land and labor, are required, to produce one hundred dollars worth of grain or stock of any kind, and what is the expense of sending it to market; and we may thus ascertain pretty nearly which may be rendered most profitable.

From the above reasoning too, we should encourage labor-saving machines in husbandry; as this tends to give us an advantage over those countries where lands are dear, by enabling a smaller capital to yield a greater profit. Thus, if labor in England be worth two shillings per day, and here it is worth four shillings, then a machine performing the labor of two days in one, is of double the value to us that it is there.

Again, from a neglect of reasoning, we often waste our labor, and of course throw away so much of the active capital of the country, by directing it to unproductive objects, from a deference to authority. We adopt foreign productions and modes of farming, without inquiring why they are valuable abroad, or whether these reasons do not fail here. I might mention many cases of this kind—for instance, in England, turnips form a cheap and invaluable winter food for stock: they are therefore made a leading crop. We are thence led to think them equally important here for the same purpose, while we neglect to remark, that there the ground is open nearly the whole winter, and the frost never severe; so that most of the turnips are fed without even the labor of removing them from the ground; but that here, they must be secured from frosts at great risk and expense, for months, and are moreover useless for feed at the time when most needed, from the severity of the weather. The ruta бага is of the same class—it is valuable there, as wintering better than the turnip, and thus supplying a chasm in feeding between turnips and grass in the spring. To us, as a crop for feeding, it fills no chasm, and serves no purpose that is not equally well done by potatoes, which are as easily raised, more easily preserved, and nearly four times as nutritious; and yet, to support a theory, we are asked by an individual* to believe that the potatoe (which to us is of more worth than the collective value of all other esculents,) is a mere compound of "dirt, water and straw."

Our climate is such that we can never expect to have a supply of green feed for our stock through the winter on a large scale, because, (aside from the difficulty of preserving it,) it is impossible that it should be eaten in the open air, at those times when it is most needed.†

that case grass should make one in a rotation of crops; and the plough will become the implement in most constant requisition. In short, no general rule on this subject can be given, which has not about as many exceptions as coincidences.

* Mr. Cobbett.

† But perhaps it is as difficult to preserve potatoes, and apply them to the feeding of stock in very cold weather, as it is to preserve turnips, ruta бага, or mangel wurtzel. We have already given a mode of preserving these roots, [N. E. Farmer, No. 14, page 106] which has not only been successfully practised by Mr. Bucl, of Albany, from whose essay it was copied, but has been in use by a gentleman in this vicinity for a

number of years, and as we are informed with perfect success. On the whole, we will copy again this mode, to save our readers the trouble of turning over our files (which we wish may be preserved to the third and fourth generation) any oftener than is necessary.

“Be it known, therefore, that mangel wurtzel, turnips, ruta бага, and we presume potatoes and other roots, may be preserved by digging about one foot deep upon the side of a hill, leaving the bottom inclining, and sufficiently broad each way to be able to pile in the space, in the form of a cone, 100 bushels [not more lest they heat, ferment and spoil.] Place the roots in it, and bring the top to a point as far as practicable. Cover with straw and then dirt. They will bear considerable frost without injury. Take care to dig a trench round the mound to turn off water. In March, or perhaps February, you may break through the frost, and take out the roots, lay them on your barn floor, and cover them with hay or straw; from whence they may be fed to cattle.”

When the roots are placed in their winter quarters care must be taken not to heap too much dirt on them at first, lest they should heat and spoil. More may be added as the weather becomes colder.

In the last number of the Massachusetts Agricultural Repository [June 1822, page 165] Mr. Prince, a practical farmer, of Roxbury, Mass. says, “I really wish farmers generally, would be prevailed on to raise a greater quantity of vegetables for the use of their stock than they have been in the habit of doing. Swedish turnips, and mangel wurtzel (of the true sorts,) are very easily raised, and every farmer has land suitable for them. These roots with care, even in pits, out of doors, may be preserved till May or June, and yield generally double the quantity that the same land would yield in potatoes. Indeed, with me I have usually had more than three times as many bushels to the acre, and with, I think, no more labor. Mangel Wurtzel will by their thinnings and trimmings, if done with care, pay all the labor of the crop, and give a fine evening food for the cows, and is also an excellent food for swine.”

The Hon. Timothy Pickering has given his opinion likewise in favor of Mangel Wurtzel, and we believe the credit of that root is too firmly established to be easily shaken in this part of the country.

With regard to potatoes being nearly “four times as nutritious” as well as being “as easily raised” as the other roots above mentioned, we must beg leave to enter our dissent; and in addition to our preceding remarks would observe, that, although according to Sir Humphry Davy, the quantity of soluble or nutritious matter in a thousand parts of potatoes is from 260 to 300, while the soluble or nutritious matter in the same number of parts of the Swedish turnip, or ruta бага, is but 64, yet the saccharine matter or sugar in the Swed-

the season. And though the practice of green feeding through the winter is much talked by theorists, it is presumed there is not a practical farmer in the state, who pursues it regularly to any great extent.

So with regard to leguminous crops, as starting point in our rotation of crops, which are so constantly recommended. They are profitable in England, for reasons before given, but with us, with the exception of peas, and in some few of beans, they are utterly inadmissible on a large scale, in any general system farming—for two reasons, first because they cannot be regularly fed through the winter when most needed—and secondly, because they require too much labor in their cultivation. We have not the labor to spare, and half our fields would lie waste, if we had first to cover them with turnips, cabbage, ruta бага, or carrots, before we were permitted to sow the wheat.

Much is said of a proper rotation of crops, but I apprehend it all results in this—that each farmer should regard his own peculiar place and vary his crops to his wants, taking care never to exhaust his lands by long continuous cropping, or by successive crops of the same kind; and above all, being careful to lay his fields down often to clover or other grasses.

In Great Britain, and in some of the old parts of our own state, flax forms a valuable staple for market, and we, overlooking material facts, are thence led to think it equally valuable here, where the expenses of raising, rotting and dressing, are equal to its whole value in market. We neglect to mark, that labor is dearer with us than them, and that as a large part of the capital expended on the crop is labor, it is therefore profitable to them, but loss to us, we expend more capital on the crop than they.

These remarks upon flax, are of course predicated on the present tedious and expensive mode of rotting and dressing it. Should the machines now offered to the public, answer to

ish turnip exceeds that in the potatoe in the proportion of 51 to from 20 to 15; and the sugar in the mangel wurtzel exceeds that in the potatoe in the proportion of 119 to from 20 to 15, and every one knows that gar is perhaps the most nutritious of any vegetable product.

It will also appear by the report of the Committee of the Massachusetts Agricultural Society on Agricultural Experiments [published in our paper No. 23, p. 17] that Payson Williams, Esq. received a premium for raising the greatest quantity of Potatoes, being bushels on one acre; and that the expense of cultivating the acre of potatoes was \$54. And that Mr. Daniel Little received a premium for raising 970 bushels; one half a bushel of Mangel Wurtzel on an acre, sides two bushels of carrots and 109 cabbages, at expense of but \$23.96—That six swine were mowed with the thinnings from the beginning of weed until about the first of October, that all this was excessive of the produce of apple trees on the same lot. These, and many other experiments which might be cited, equally conclusive, lead us to believe that potatoes are not generally so easily nor so cheaply raised as Mangel Wurtzel. And we are constrained to believe, notwithstanding the “authority” of Mr. Burr, that potatoes may be less profitably raised as food for stock than Mangel Wurtzel. We may, however, in an error, and if so, are open to conviction, and refer to acknowledgment our aberrations.

urpose intended, that of dressing flax at a small expense, without rotting, (and that they may be confidently expected.) then may we assuredly find it this as a new era in agriculture, inasmuch as we shall be in immediate possession of an elegant staple, to which our soil is generally well adapted, equal at least in value to the cotton of our southern brethren, and which we can furnish at a less expense per pound than they in their cotton, with all their unenviable and unhallowed aids of "sinews bought and sold."

5th. In selecting implements of husbandry, pay no regard to fashion, but examine each article for yourself. See that it is fit for the use intended. If choosing a plough, for instance, never buy it for its name, whether made by Mall, or Wood, or Burden, or Wright. Is your land free from obstructions, and do you wish to do your work well, and with the least possible power of team, choose a plough that presents the least resistance to the soil, and which, from its length and just proportions, enables you to make neat and thorough work: but if your land is still covered with stumps, which leave you scarce room between one stump and another, to parade your team with a plough a dozen feet long at their heels, then try to contract the length of your plough as much as you can, and still be enabled to make tolerable work, as this will save you many balks in your field, and much difficulty and delay in managing your team. Is your land new, and filled with roots which you wish to exterminate—see that your plough be firm, compact and strong, relying on your additional strength of team to carry you through. In short, suit your means to the end designed, and this single simple rule will save you a vast deal of loss and trouble in all respects.

From the foregoing remarks, we may see the necessity of examining facts on general principles, and the danger of relying on authority in the importation of grains, implements and modes of husbandry from abroad, and of trusting to experiments made under circumstances that are unexplained or misunderstood. We see that in England, whence are drawn many of our most valuable improvements, things are often profitable and necessary, that are useless here.—Hence, often, English farmers, on first viewing our style of farming, think it utterly inferior to theirs, when, perhaps, it would be no difficult task to prove, that in the legitimate pursuits of agriculture, viz. the comforts and moral improvements of our population, and for profits of capital employed, we far excel them. Hence too, we are often urged to adopt modes and projects, which, though justified by favorable circumstances abroad, are preposterous here.

To illustrate this, I might refer you to the opinions of many respectable men daily published among us, which are utterly fallacious. Let me point you to a single instance: In one of our most valuable agricultural publications, I have noticed several able letters on Flemish husbandry recommended to our attention—one leading trait of which style of farming is, that the lands are to be dug over with the spade to the depth of eighteen inches, every three or four years! Now this may doubtless be good husbandry in Flanders, where the country is crowded with a population that must be employed and fed, and in order to which the last bushel of grain must be wrung from the earth, without regard to the labor required to produce it—

while in our fertile and happy country the case is entirely different, and the attempt would be absurd and ridiculous.

Here then let us pause for a moment, and call to our aid sober reason and observation. Let us scan closely the claims of every innovation, in order to adopt it if useful or reject it if useless. So far from retarding improvement, this will accelerate its progress, by sweeping from its path much useless matter that now encumbers it. The fashion of the day leads us too far into wild theories and visionary projects;—we go on loosely and unprofitably, without accuracy and without method. I repeat it then, we want at present, not so much crude materials, as accuracy and system in *investigating* and *arranging*, that we may reject or adopt for practical purposes.

I might proceed to remind you, Gentlemen, of various rules which should not be forgotten, but I have already been led to detain you longer than I had intended. My object has been chiefly to draw your attention from splendid theories and experiments, to the ordinary but important concerns of your own farms.

Permit me now to add a few remarks on the objects of our agricultural association, and particularly on the rewards we bestow on prize stock and crops. Their effects are, I fear, in some respects injurious to the true interests of agriculture, by encouraging the growth of *monsters* by inordinate means.

So far as extraordinary crops can be produced from improved modes of culture, or superior stock raised by introducing new species from abroad, or skillful crossing at home, they add to the valuable interests of the community; but to know how to produce one extraordinary animal only by *storing his mate*, or to make two blades of grass flourish where but one grew before, only by robbing the next field of its due proportion of nourishment, adds nothing to our stock of valuable knowledge, or the prosperity of the country.

Beauty, in every system, is founded on the symmetry of its parts, and whatever tends to destroy its just proportions in one particular, must be viewed as injurious to the whole. If, then, premiums for large crops, without regarding expense, tempt to an undue use of our farming resources, and this is evidently their direct effect, then it must follow, that they are injurious to our interests. This idea, however, is suggested with great deference to the present general opinion and practice; but may I not ask, has not this practice grown out of the erroneous position, that good husbandry consists in producing the greatest crops? whereas, to judge of its excellence, we ought first to know the expense of producing them, in order to estimate the profit on the capital employed.

Should not the premium be more justly due to him who should instruct us by a skilful and judicious application of labor to land, how to raise a hundred bushels of grain at the least possible expense, than to him who, by an unprofitable and extravagant use of his farming resources, should force it from a single acre? In short, have we not adopted a wrong principle on which to ground our rewards, by mistaking the object to be attained, and bestowing them on the gross amount of produce, and not on the net profit of the capital employed?

Let us then require of each claimant, at least

a statement of his *expenses*, as well as the mode of culture—we may then judge whether his mode be profitable, and ought to be adopted. We want chiefly to learn economy in the skilful application of labor to land, in order to render every acre most productive; for we must still bear in mind, that with us labor forms the principal item of capital expended in our farming operations, and that we are limited in our supply of it.

Again—might not a competition of a higher order among us be excited, by inviting each farmer who wished to compete with his neighbor in good husbandry, to keep for exhibition a general account current with his farm, and then award premiums in proportion to his profits on the capital employed, and his skill in managing it? This plan would seem difficult at first view, but forms might be drawn and blanks furnished by the society to its members, so plain and simple that every man of common capacity might soon learn to keep his accounts correctly. This would tend directly to the practice I have before recommended: it would enable us to take more correct and comprehensive views of our own operations, and shew in what respects our efforts were well directed: it would exhibit to us the amount of our farming concerns, and prove to us whether we were applying our labor to the best advantage, and rendering our capital productive: it would, in fact, render each man's grounds a pattern farm for his improvement, as it would not only show him what was most profitable, but would record the facts for his future use; and thus much valuable information, which is now daily acquired, and gradually lost for the want of some place in which to treasure it up, would be preserved, and the *farm book*, if fairly kept, would soon become an interesting repository of valuable knowledge.

To conclude—let us never deceive ourselves with the expectation of sudden or extravagant gain. In every course of life, but more especially in farming, such hopes are entirely fallacious. Every thing depends on patient industry, properly directed, and a well regulated economy in the use of means. It is an error to suppose that this country is in want of valuable staples for market, in order to render it prosperous, although I am aware that a different opinion has prevailed. The difficulty lies, not in want of subjects of profit, but of skill in selecting and improving them.

"Knowledge is power."—On looking around us, we see that each farmer who improves the advantages of his situation with a moderate degree of skill, industry and economy, lives comfortably, and renders his farm profitable; while his neighbor, who may be equally industrious and economical in his style of living, but wants skill to direct his efforts to advantage, is continually toiling on from year to year in difficulties, and left to complain that the country is going to ruin for the want of something that can be raised worth carrying to market.

General prosperity is composed of individual successes, and where every farmer has it in his power to succeed, we must conclude the country is prosperous, or that causes operate of which we are not aware. May not these causes be traced to other sources than bad farming, to wit: to *bad living*—to habits of indulgence and ease, of waste and general extravagance?

It may be confidently asserted, that there is

not throughout the known world, a country where so great profusion reigns among all classes of society, as our own. Half the waste and expense in foreign luxuries in which we indulge, would impoverish the finest country in Europe; and while we retain these habits, we may ever expect to hear the cry of poverty through the land, though every vegetable production of the universe were flourishing around us, or the wealth of India were devoted to their culture.

Let us cease then to look abroad for sources of sudden wealth—Let each of us attend to his farm understandingly—Let him know his own plan and pursue it steadily—Let him do his work well and in season—See that all is in order, and fit for what it is designed—Contribute cheerfully to objects of usefulness and public improvement, regarding with anxious care the interests of his church and schools—Let him discountenance idle and vicious habits, and promote good conduct and vital piety in the circle around him, by his own example—Let him, in short, strive earnestly to discharge his duty to himself, his neighbor, and his God, and he cannot fail of success; but with an approving conscience, and the smiles of heaven, may justly claim to himself the enviable rank of an honest, intelligent, and independent *American Farmer*.

From the Old Colony Memorial.

I observe in your paper of the 30th November, under the head of agricultural economy, an account of the clearing an acre of swamp, which was covered with stumps and roots, and which was with the hoe, entirely subdued by the labor of one man in eighteen days, and an half!

It is understood also that the land which produced the hay, for which the premium was bestowed by the Plymouth County Agricultural Society, was two years before, in the state of nature, a swamp, covered with alders and whortleberry bushes!

It is gratifying to observe the attention of the husbandman turned to this object; as this species of land affords the best resource for grass of any in the country, and has been heretofore too much neglected, from an ignorance of its value, or an imaginary difficulty, or overrated expense of labor, in reclaiming it.

There is in every town, large tracts of this description of land (viz. swamp, bog, or morass) perhaps on every farm more or less, perfectly waste, and which if reclaimed and cleared, is capable of becoming the most productive, and permanently valuable, for mowing or for grass of any in this part of the country, it is imagined that expediency, if not necessity calls for more attention to this object of improvement.

The climate of our country, and consequently the seasons, have undergone a great change even within the memory of many now living, and a consequent change in the attention of the farmer has become necessary, to obtain the object of his supply. I do not allude to the drought of the last season; nor to any occasional drought to which we have always been more or less subject—but it is notorious the climate has become more arid, there is less rain, and less snow; many of the ponds are nearly dry—some quite, where there were formerly seven or eight feet of water—the springs are uniformly lower—the swamps not so much overflowed. This is by some, supposed to be the natural consequence of the clearing off the forests, and laying the

face of the earth more open to the evaporation of the sun and wind—whatever may be the cause, it is no part of my present object to account for it; I will leave that to the philosopher.—Assuming such to be the fact, my object is to invite the farmer to turn his attention to such improvement of his means, as to secure himself and his country from part of the evil, which may otherwise ensue on the failure of crops; either from drought, or from the infinite variety of devouring reptiles: the security from both, is perhaps, to be sought for, with the most flattering prospect of success, by the recurrence to this species of land for improvement and cultivation; as the Grub, from which we have suffered so extensively, for the three last years, has never been observed to resort to those lands, which are sufficiently saturated with moisture.

It is an observation frequently made, that farmers are peculiarly wedded to their habits, are inordinately attached to their particular mode and process of cultivation, because they are derived from their ancestors, and are sanctioned by their experience—this is all natural—but farmers like other men, must change their habits with the change of circumstances, they are hawk eyed to see where there interest may be promoted, and if they are not much given to speculation and enterprise, when any improvement is introduced they are not slow to discern its advantage, and adopt it.

When the venerable Pilgrims, our fathers, first migrated to this country, they were a feeble band, and in slender circumstances; they had a wilderness before them, and wants and hunger pressing on their rear—they could not adopt the slender improvements in agriculture then known in the mother country—they could only avail themselves of the few plats of ground cleared by the natives to deposit their seed corn; when that was done, they necessarily cleared for their further improvement, that which was within their means, that which could be effected with the least possible labor, and would make them the most immediate return; this of course, was the upland, and those of the lightest consistence, as best calculated to furnish them with that necessary article (and of difficult acquisition) *bread*; this was necessarily their first object of pursuit; and this the foundation of that system of farming, which by a view of the present face of the country, will be judged to have been too literally followed by their successors, although relieved from that "imperious necessity," whose iron grasp pressed so heavily upon their fathers. The circumstances of the Yeomanry of the country, are now easy and independent, and this is the day of improvement—their industry if excited to enterprise, under the wise and discreet patronage and encouragement of agricultural societies, is capable (if not of counteracting the seasons) of subduing nature, and making her tributary to their necessities, comforts and luxuries. It is with satisfaction I observe the Agricultural Society of this county, have wisely turned their attention to this neglected object of agriculture, and have offered their premium for the encouragement of those, who shall successfully reclaim a specified quantity of swamp or fresh meadow to English mowing—this is wise and discreet in them, and there are perhaps some whose circumstances and situation may enable them to avail themselves of the encouragement, and to their own exceeding

profit; but it is no part of my desire to excite a quixotic enterprise, even in this laudable pursuit—such an undertaking as may induce individual embarrassment—my wish is to route the general attention of all those who may have such waste lands near or on their homestead, and make it a sort of *common-place* object, where they may profitably employ themselves and their laborers, in their *broken hours or days*, when our objects are not imperative; and if this way they may reclaim forty rods in the year they will have added so much to their capital and will have placed it at compound interest.

I am aware that this county can never be distinguished as an agricultural county; if it ever arrives at distinction, it must be as a manufacturing district, for which its numerous streams offer so many facilities, but in this view its agriculture is of importance as the hand-maid, or even the pillar on which manufactures must be supported—and manufactures also when more largely established and endowed, will react on the improvement of agriculture; for they must have observed but very little, who have not remarked the bold and liberal spirit of improvement, which persons bred to trade or manufactures have often exerted on the improvement and embellishment of their land estates that they usually come to them with a more abundant command of ready money, than most farmers possess; and that they have generally by long habits of calculation, better and more enlarged ideas of the propriety of expending, in order to acquire; and by these means numerous, beautiful and flourishing villages have already been erected in the wilderness, and some where nothing before but the footsteps of the savage, or the prowling wolf were known to roam, and how has agriculture had reason to bless that happy alliance—and how miserable must the policy of that government be which would disjoin the agricultural, manufacturing and commercial interests, or make one tributary or subservient to the other. YEOMAN.

THE FARMER.

BOSTON:—SATURDAY, JAN. 13, 1823.

IMPROVEMENTS IN HUSBANDRY, AND NEW IMPLEMENTS OF AGRICULTURE.

The excellent Address of Mr. Garnett, delivered before the Fredericksburgh Agricultural Society, in Virginia, and published in our paper, No. 21, page 164, contains some humorous and happy illustrations of the slow march of improvements in husbandry, and the pertinacity with which some farmers adhere to old customs, although very absurd and inconvenient. It is owing, principally, to this obstinate predilection to established usages, that agriculture has, till within half a century past, been so much in the rear of some other less useful arts, and exhibited but feeble traces of that march of mind, which has been evinced by advances in chemistry, botany, mineralogy, and the whole circle of those sciences, which give to civilized man his best founded claims to superiority over the undisciplined and unlettered savage. The prejudice of the Virginia cultivators in favor of their unwieldy, inconvenient, old-fashioned ploughs, was ridiculous enough, and the folly of that foolishness, which induced them to persevere in the path of error, after experiment, the unerring test of utility, had pointed out a better way, may as well be laughed at as gravely rebuked.

ut this reluctance to adopt evident improvements
thing new in the history of man, and has ever been
iculary prominent in the annals of agriculture.—
have no doubt but even our New England farmers
wrought with poor tools, when better might be
, and which would, at least, "in the long run,"
e cheaper than those which they ought to super-
e.

We would, not, however, censure our cultivators for
blindly and precipitately adopting every practice
ch is stated to be an improvement. But as res-
ts tools of every day employment, when many times
are inspection, and almost always a short trial would
ve some to be more useful than others, to adhere to
e which are least commodious, and to refuse to
e even an experiment with a new one, merely be-
se "father didn't do so," or "neighbor Blueskin
s it won't do," is a kind of pertinacity which de-
ves to make its possessor a mark for all the arrows
ch the quiver of wit can furnish.

We believe, however, that many farmers of Great
ain are more obstinately attached to silly, expen-
sive, and unhandy customs, than any of our yankee
tivators. And if Brother Jonathan is sometimes a
le backward about embracing new and useful im-
vements, John Bull is often a very paragon of awk-
d obstinacy. An English author (Lawrence, on
at Cattle,) mentions a report of "a gentleman who
ks eight large oxen on a plough, whatever the soil,
ng or weak, fresh or fallow;" and says he has wit-
sed "in an English district, where as good laboring
n are bred as we have in England, farmers often
e ten oxen together to one plough, and stand to it
ily, as a matter of necessity; which I should by no
us controvert were the exertions of the brutes equal
tiffness and energy to the prejudiced arguments of
ir masters."

It is likewise observed by Sir John Sinclair, that
e introduction of new implements into a district, is
n a matter of the greatest difficulty, owing to the
rance, the prejudices, and the obstinacy of farm-
rants and laborers. Many farmers, therefore, very
urdly retain their old implements, though convinced
heir inferiority, rather than sour the temper of their
rers, by attempting to introduce new ones. In
ay cases, however, they have succeeded by atten-
n, by perseverance, and by rewarding their servants
o have been induced to give the new machines a
trial."

The yeomen of New England are too enlightened to
under the dominion of such unprofitable prejudices.
ey will assent to our assertion, when we say that a
n who works with a poor instrument, when a better
conveniently be had, is himself

But little better than "a tool,
Which knaves do work with, call'd a fool."

We are therefore happy to perceive that a Shop or
arehouse, for the sale of Agricultural Implements, is
established by Mr. J. R. Newell, No. 20, Merchant's
w, Boston, where Ploughs, Cultivators, Forks, Hoes,
, &c. &c. of the latest and most improved construc-
as, are to be sold, at a cheap rate, and of an excel-
l quality.

NEW SYSTEM OF SHOEING HORSES.

In our paper of Nov. 20, page 142, we took notice
a work entitled Goodwin's "New System of Shoe-
g Horses," &c. and beg leave once more to turn
t attention of such of our readers as are, or ex-
pt to be, benefited by the labors of that valuable and
ble animal the Horse, to this little treatise, which
ay be had at any of the principal bookstores in this
y. If a horse has naturally all the good qualities

that ever belonged to his species—is fleet as the Bu-
cephalus of Alexander, strong as the largest and most
powerful English dray horse, and docile as a lap-dog,
still, if his feet are defective, he is good for nothing.
An attention, therefore, to the "Diseases of the Foot
connected with shoeing," (the principal object of this
treatise,) is of primary importance. Dr. Franklin,
somewhere, tells us of a horse's being badly shod,
which caused the loss of the horse, and the loss of the
horse occasioned the destruction of his rider; and this
last greatest of all disasters was the consequence of the
rider's not possessing such a treatise as we are recom-
mending, and paying a proper attention to its direc-
tions. Should any person hereafter, who has a dollar
to spare for this work, refuse to purchase it, and thus
meet destruction in the way warned against by Dr.
Franklin, the verdict of the Coroner's Jury ought to be
felo de se; or in English, *this man's neck was broken in
consequence of his own carelessness*.

Plan for doubling our Subscription List.

We have thought of a scheme, which, if put in ex-
ecution, will be sure to benefit the public, as well as
prove serviceable to our establishment. This is, sim-
ply, for each of our subscribers to procure us at least
one other subscriber; and we hereby authorize each
and every lady and gentleman, who takes the N. E.
Farmer, to become our agent for that purpose. Those
who do not like this project, will of course let it alone,
but we can assure them that our advice is dictated by
pure patriotism, with a slight tincture of regard to our
own interest.

FARMER SUMMARY OF NEWS.

In CONGRESS but little business capable of detail in
our paper has yet been completed. The MASSACHU-
SETTS LEGISLATURE is likewise principally engaged in
concerns of a local and private nature. In both
those bodies as much harmony and unanimity prevail
as is consistent with freedom of discussion, and that
amicable collision, which is necessary to elicit the
light of truth.

FOREIGN.—A late arrival at New York, has brought
London dates to December 5th, which are much more
interesting than usual. The Congress of Verona is
broken up, or rather split into several sections. That
part which is to regulate Spain, is to sit in Paris; the
portion which is to control Italy, is to hold its meetings
at Vienna; and the Emperor Alexander, wherever he
may be, is to take charge of the rest of Europe.

France seems to be determined to restore the old or-
der of things in Spain, either by force or menaces. Some
accounts say that a body of the French army of Obser-
vation has already penetrated into Spain, others that
Spain is to have a little time to accede to the decisions
of the Congress, and to ward off the meditated blow
by submission. The Cortes, on the contrary, shew no
disposition to submit to French dictation, and appear to
be determined to manage their own affairs in their own
way. If war does not follow, one or the other party
must *haul in their horns*, and if it should take place, it
is impossible to foresee how many nations will become
parties. Great Britain seems determined on neutrality.
Probably the government tends one way, and the people
the other, and in this way John Bull seems suspended
on the horns of a dilemma, and will, it is to be hoped,
be kept out of mischief.

On the 20th of Oct. the Turkish and Greek fleets
met, and a combat took place which lasted six hours,
and was obstinately contested. A part of the Greek
fleet was kept out of action by adverse winds and cur-
rents, but they succeeded in repulsing their opponents.
The Greeks fought bravely, for they fought in presence
of their wives and children who covered the hills and
shore.

It is estimated that more than a million bushels of
bones, human and inhuman, were imported last year
from the Continent of Europe, into the port of Hull in
England. The neighborhood of Leipsic, Austerlitz and
Waterloo, and other places, where, during the late

bloody war, the principal battles were fought, has been
swept alike of the bones of the horse and his rider,
shipped to the port of Hull, and forwarded to the York-
shire bone-grinders, who have erected steam engines,
with powerful machinery, for the purpose of reducing
them to a granular state. In this situation they are
sent, chiefly to Doncaster, one of the largest agricultur-
al markets in that part of the country, and sold to farm-
ers to manure their lands. The oily substance gradu-
ally evolving as the bone calcines, it is said, makes a
more powerful and substantial manure than almost any
other substance. This is remarkably the case with
human bones. A dead soldier is thus made an article
of commerce; and it is possible that the Yorkshire farm-
ers may thus be indebted to the bones of their child-
ren for their daily bread.

There has lately occurred a terrible hurricane, ac-
companied with an inundation, in Genoa. Bridges,
trees, and houses, were swept away by torrents descend-
ing from the mountains. The Lazaretto, a fine and
massy building, containing a large quantity of merchan-
dize, was borne away by the violence of the waters.—
The environs of the city presented an immense lake of
muddy water, with here and there tops of trees and the
second stories of houses, rising above the element.

The town of Port-au-Prince, St. Domingo, was nearly
destroyed by fire, which broke out on the night of the
16th ult. and was not got under until the 19th.

A Frenchman named Jacques, who is termed the
French Giant, is exhibiting himself in England.—He
is seven feet four inches in height, (and is yet a youth.)
is well formed, and of amazing muscular powers.

DOMESTIC.—The whole number of passengers ar-
riving from foreign ports, in the ports of the U. States,
from the 1st of Oct. 1821, to the 30th Sept. 1822, is
reported by the Secretary of State to have been 6482;
5241 males, and 1136 females—the sex of the remain-
der not being reported to the Department of State.

Edward P. Perley, who kept a store in Market St.
was arraigned before the Police Court last Saturday,
charged with having purloined goods from the store of
Messrs. Draper & Stone. He was ordered to recognize
in the sum of \$4000, with sureties, for his appearance
at the Municipal Court.

Gen. Chandler has been re-elected to the Senate of
the United States, for the State of Maine, for six years
from the 4th of March next.

Counterfeit \$5 and \$2 bills of the Concord, N. H.
bank, are in circulation. The paper is of a lighter
and more spongy kind, than the genuine. None but
the above description, are known to be counterfeited.

At Richmond, Va. on the first of Jan. nearly all the
printing materials in the office of a paper called the
Hornet, were destroyed by a mob of 15 or 20 persons
with blackened faces.

The Legislature of N. Carolina has abolished impris-
onment for debts contracted after the 1st of May next.

The U. S. NAVY list shows that one hundred offi-
cers, or one eighth of the whole number, have resigned
or died during the past year.

Flour 110 dollars per barrel!—The Baltimore A-
merican of Friday says, "Late accounts from the Pa-
cific, received in this city last evening, via Panama and
Chagres, announce that flour had risen to one hundred
and ten dollars per barrel at Guayaquil."

Fashionable Amusement.—Among the holiday sports
of the season, a writer in the Freeman's Journal de-
scribes a *Bull-bait*, witnessed by him at Rose Hill, near
Philadelphia, on Tuesday last, in colors calculated to
excite the attention of the magistrates of a country
less distinguished for humanity than the "city of brother-
ly love."—N. Y. Statesman.

Several families have recently sailed from N. York
for St. Augustine, L. Florida, to settle upon the Alachu-
ua tract, so called, which is represented to be the rich-
est tract in Florida, producing sugar cane and rice in
abundance. These lands are valued from one to two
dollars per acre.

Purcell, the free man of color, who gave information
of the late intended insurrection in the state of South
Carolina, has been handsomely rewarded by the Leg-
islature of that state. They have allowed him \$160 a
year for life, and exempt him and his family from taxa-
tion.

From the New-Brunswick Advertiser.

A SONG,

Written by John J. Barker of this city, and sung at the Spring meeting of the Agricultural Society of New-Brunswick, on the 24th April, 1821

A Farmer's life's the life for me,
I own I love it dearly;
And ev'ry season, full of glee
I take its labor cheerly—

To plough or sow,
To reap or mow;
Or in the barn to thresh, Sir.

All's one to me,
I plainly see
'Twill bring me health and cash, Sir.

To customers the merchant show
His best broad-cloths and satin;
In hopes to sell a suit of clothes—
But lo! they beg a pattern—

Which pinn'd on sleeve,
They take their leave—
"Perhaps they'll buy—since low 'tis"—
And if they do,
The sale he'll rue,
When paid, Sir, with a "notice."

The Priest has plagues, as undesir'd,
When flatter'd with a call, Sir,
For tho' he preach like one inspir'd,
He cannot please 'em all, Sir.

Some wanting grace,
Laugh in his face,
While solemnly he's prosing;
Some sneeze or cough,
Some shuffle off—
And some are even dozing.

The lawyer leads a harass'd life,
Much like a hunted Otter,
And, 'twixen his own and others' strug,
He's always in hot water.

For foe or friend
A cause defend,
However wrong, must he, Sir,
In reason spite
Maintain 'tis right—
And dearly earn his fee, Sir.

The Doctor's styl'd a gentleman,
But this I hold but humming;
For like a tavern waiting man,
To ev'ry call he's "coming"—
Now here, now there,
Must he repair,
Or starve, Sir, by denying;
Like death himself,
Unhappy elf,
He lives by other's dying.

The soldier deck'd in golden lace,
Looks wond'rous fine, I own, Sir,
But still I envy not his place—
When batter'd to the bone, Sir
To knock my head
Against cold lead,
I never had a notion;
If that's the way
To rank, I say—
Excuse me the promotion.

The sailor lives but in a jail,
With all the risk besides, Sir,
Of pillage, founder, and of gale—
This cannot be deny'd, Sir.

While I so snug
Enjoy my mug,
Or kiss my wife and so forth—
When rain and storm
The nights deform,
His duty bids him go forth.
A farmer's life, then let me live.
Obtaining, while I lead it,
Enough for self, and some to give
To such poor souls as need it.
I'll drain and fence,
Nor grudge expense
To give my land good dressing.
I'll plough and sow,
Or drill in row,
And hope from Heav'n a blessing.

AGRICULTURE.

From the New Hampshire Sentinel.

CHESHIRE AGRICULTURAL SOCIETY.

At a meeting of the Cheshire Agricultural Society at Col. Drew's in Walpole, on the first day of January instant, the following premiums upon Agricultural products were awarded by the executive committee.

To Bela Chase, of Cornish, for the best crop of wheat on old ground, being 44 bushels on one acre and 22 rods of land, \$4.00

By the statement of Mr. Chase, accompanying his application, it appears that this piece of land is a part of a loamy pine plain. That previous to 1820 it had been for some years alternately in tillage and mowing. In 1820 and 21 was planted with corn, and in the latter year highly manured, quantity not stated. In the spring of 1821 the land was first ploughed deep, the manure spread and covered by a shallow ploughing, planted, and the corn carried off the ground the first week in September. The produce as estimated by measuring in the ear, and shelling one basket, was 102 bushels. The land was again ploughed deep immediately after harvesting the corn and sowed, 5 pecks on the piece, harrowed once and bushed—produce as above.

To Samuel Grant, of Walpole, the second premium on wheat, \$2.00

Mr. Grant's field contained 2 acres 3-1 and 14 1-2 rods. The produce 94 bushels. The wheat, a specimen of which was exhibited to the committee, of a superior quality; weighing 64 lbs. per bushel. The field in 1821 was tilled—a part of it sowed with peas and the remainder planted with corn. The peas were harvested about the first of August—a large crop of weeds then ploughed in and the ploughing repeated three times before the 20th Sept. From the part of the field planted, the corn was removed on the 15th Sept. and stooked up on grass land where it ripened well. The land was ploughed between that time and Sept. 20th, three times, at the last of which ploughings it received a dressing of chip manure. Sept. 20th, the whole piece harrowed and sowed with four and a half bushels. The seed was prepared by washing and mixing with each bushel two quarts of slacked lime. May following it was dressed with two bushels of plaister and one of slacked lime. Mr. Grant expresses the belief that the frequent ploughing and turning in of the weeds contributed very much to the increase of his crop.

To Samuel Jennison of Walpole, for the best crop of potatoes, a premium of \$4.00

The quantity of land, one acre, produce 45 bushels of the long red or Spanish potatoe. The land had laid in green sword mowing, 12 or 15 years. Ploughed again and harrowed in the Spring of 1822—manured with 30 loads of coarse manure spread. Again ploughed and harrowed—furrowed 3 1-2 feet distant one way—manured in the furrows with 11 loads of rotten manure—bills 1 foot and an half distant; hoed twice and harvested last of October. Set whole, about one large potatoe to each hill.

SAMUEL FINDLEY, Chairman.
THOMAS M. EDWARDS, Secretary.

JANUARY.—Carefully watch cows, near time of their calving; see that they are not allowed to leap fences or ditches, or go on the ice; house such as have just calved; increase their feed; put ewes to rowen that are soiled to lamb, house your calves and colts, finish killing and curing pork, lay up your tools carefully that were used in fall work, finish your threshing, get home your wood, dress flax for your daughters to spin, and settle your accounts. *Agri. Almanac.*

BROWN'S PATENT VERTICAL FAMILY SPINNER.

FOR SALE, at the Agricultural Warehouse, Chambers No. 20, Merchant's Row, (opposite the East end of the Old Market)—a number of

Brown's Patent Family Wool Spinners, which are found on trial to be one of the most useful domestic implements that have ever been invented for that purpose, being of so simple and easy construction that a girl of the age of 15 can well do the work of persons in spinning, and so compact in its form as to require so much space as a common family spinning wheel. The advantage of this machine over and above the common mode of family spinning, is at once testified in a few minutes operation with the machine; it once discovers its immense saving of labor, its accuracy in spinning a good thread, and the quantity it produces. It requires no further examination to judge of its utility than to see it operate. It is afforded at a low price as to bring it in common use to every practical farmer, and is well calculated for the employment of the inmates of our common town's poor houses. Any number of Machines can be furnished at the shortest notice, and warranted. Jan. 11.

THOMAS W. SHEPARD,

RESPECTFULLY informs his friends and the public that he executes all kinds of

BOOK AND FINE JOB PRINTING, in the most fashionable manner, and on reasonable terms, at the Office of the NEW ENGLAND FARMER, ROGERS' BUILDING, CONGRESS-ST.

NEW ENGLAND FARMER.

Published every Saturday, by THOMAS W. SHEPARD, Rogers' Building, Congress Street, Boston; at \$2.50 per ann. in advance, or \$3.00 at the close of the year.

Vol. I.

BOSTON, SATURDAY, JANUARY 25, 1823.

No. 26.

DISEASES OF CATTLE.

SELECTED AND COMPILED FROM THE BEST AUTHORS,
BY THE EDITOR.

Gripes, or Flatulent Colic.

This disease, in horned cattle, is generally the effect of costiveness, or a retention of food in the third stomach. Sometimes, however, it happens when the bowels are in a lax, or natural state. Cows that are fed upon grains are very liable to this complaint; such, also, as are kept upon dry food are often attacked by it. When colic takes place, independent of costiveness, it is generally occasioned by feeding greedily upon fresh succulent grass, or by drinking cold water when heated by exercise, and comes on rather suddenly; but when it is caused by costiveness, the attack is generally more gradual.

The symptoms are at first, an appearance of stiffness in the animal, often lying down, moaning, or striking against the belly with the hind feet or horns. The body is often swollen, which is most observable on the left side. The pulse is generally in its natural state. If proper remedies are not administered, the pain becomes more violent, and at length inflammation takes place, which is indicated by the pulse coming very quick, and the ears, horns and feet cold; when this happens the disorder most commonly terminates in death. When the colic appears to arise from costiveness, purging medicines are of course the essential remedy; but they should be combined with aromatics, or mulants, as in the following prescriptions; and if the animal is in good condition, or the inner surface of the eyelid is unusually red, it could be bled freely; but if the complaint is attended with looseness, or the bowels are in their natural lax state, particularly if the animal appears rather weak, and the inner surface of the eyelid pale, the following carminative drink should be given, and no blood taken away. When the purging drink is found necessary its operation may be promoted by clysters. It may not be unnecessary to observe that when the colic is caused by feeding greedily on grains, or any other kind of food, the cow must be fed cautiously for several days after, and take the carminative drink, hereafter mentioned, once or twice a day, in order to restore the tone or energy of the stomach. On the other hand, should the disease have been occasioned by costiveness, or feeding upon dry food, the state of the bowels must be attended to after the animal has been relieved by the operation of the purgative drink; as the tendency to costiveness will probably continue, unless it be removed by a change of food. When this cannot be done, some salt should be mixed with the food if the animal will eat it; if not he should be drenched with three or four ounces of salt dissolved in water daily, which will serve to open his bowels in a slight degree, and increase his appetite for water, with which he should be freely supplied.

Purging Drink.

Barbadoes aloes	1/2 oz.
Carbonate of potash, or common potash	3 dr

Powdered ginger	1/2 oz.
Water	1 pt.
Oil of turpentine	1 oz.
Linseed oil	3 oz.

Mix for one dose.

When the above medicine cannot be procured in time, the following may be substituted for it.

Common salt	1/2 lb.
Sweet oil, linseed oil, or any kind of oil which is not very rancid, or even melted hog's lard	1/2 lb.
Flour of mustard	1 oz.
Water	1 qt.

To this a glass of spirit may be added.

Stomachic Drink.

Powdered ginger	1/2 oz.
Powdered gentian	1 oz.
Carbonate of ammonia [volatile salts]	2 dr.
Infusion of camomile flowers	1 pt.

Mix for one dose.

Carminative Drink.

Oil of turpentine	1 oz.
Tincture of opium	6 dr.
Spirit of nitrous ether	2 oz.
Water	1 pt.

Mix for one dose.

White's Treatise.

Indigestion, or loss of the Cud.

Mr. Lawrence says that in this disease, "the beast mourns, and has no appetite, or drops its food without attempting to swallow it. Probably from defective irritability in the fibres, or contracting muscles of the rumen or cud-bag, the animal is unable to throw up or ruminate, of course the bag remains loaded and obstructed. The intention is to remove the obstruction and re-invigorate the animal fibres. Let the animal fast some time, then give a warm bran, or pollard mash, with good hay and warm water with salt. This treatment alone may succeed with patience, even should the maw be obstructed by acorns or crab-apples. An aloes tincture made with brandy and ginger or capsicum [red pepper] might be of use in this case. After conquering the obstruction, bitter infusions made of camomile, hoarhound, oak bark, &c. in beer, may be required, as restoratives, although perhaps good dry nourishing feed will have an equally good effect."
